# STUDY OF SHAPES AND CONCEPT OF

## FIELD OF COHERENCE

Presentation for beginners

### INTRODUCTION

This course is written for the first time. It has been given many times since the 1975s. It is a simplified presentation which serves as a starting point for those interested in what relates to forms and what we have been developing for a number of years, and which we call *Coherence Fields*. Theoretical developments will not be discussed here. It will be necessary to refer to read the works of Jacques Ravatin "Theory of Coherence Fields" <sup>1</sup> and of Jacques Ravatin and Anne-Marie Branca "Theory of Forms and Coherence Fields", work in the process of being finished. The latter makes it possible to enter completely into this new theory which contains a model of thought.

Many congresses have been organized by the ARK'ALL group. The last was held in Camac in July 1996. It was organized by Anne-Marie Branca and Bernard Menguy, the latter an architect in Camac and a member of the ARKOLOGIE association whose creators are Serge and Françoise Hennemann, both architects. These people can be contacted for any housing project, as can Luc Labat and Sophie Nouvel of Sté Barka.

## Chapter I

### The Forms Seen by the Ancients and the Moderns

Shapes are linked to marks or are marks themselves.

The benchmark, for this study, is fundamental. It allows the observer to describe what surrounds him. He projects his landmarks into the infinitely large or the infinitely small. It describes itself by reference points.

The coordinate system can be a system of axes from an origin and a unit of measurement; it can be of a comparative order: better than, more beautiful than... It can even correspond to a vague nature which will make it possible to give a more precise description. It may be linked to the notion of belonging: to "contained in...".

This landmark is important because we are going to postulate "existence without landmarks".

Thus, in human life, we use concepts where there is no measurement, no benchmarks. Also we find the following concepts: love, kindness, unbearable pain, both physical and moral, etc.

This existence without landmarks will be called "*the Global*", the existence with landmarks being "*the Local*".

There will only be a *Global* while we can find "*Local*". The world described by rational thought is a particular "*Local*", but other "*Locals*" are possible. Travelers have sometimes described it. Our society refuses these contributions that it cannot assimilate.

All of this is part of "Coherence Field Theory <sup>2</sup>".

We will not say that the concepts of love, fear, intense pain, state of well-being... are in the *Global* because it would then have a notion of belonging, therefore a setting up of benchmarks, but rather linked to the *Global*. "To be bound" in the language of forms as we develop it does not entail the concept of landmarks.

<sup>2</sup> See the works of Vladimir Rosgnilk, Jacques Ravatin and AM Branca

The form is for us more or less identifiable - It can be in the *Local* for example the usual local, that is to say as it was presented to us, imposed

It can be only partially in the *local*, "another part" of this form being linked to the *global* - here we must be careful because the expression "another part" entails a delimitation, therefore a location; it is then necessary to know that this expression is not adequate, but one can employ it without fear of errors because one will see that to test a form it is necessary to have a correct representation of it. Representation, that is to say everything that is arranged as knowledge, point of view on the arrangement of concepts and concepts themselves, is fundamental.

One can ask the question, from the moment when the form is more or less present or more or less absent in the space-time structure [ E - T ], that is to say is as fundamental as this structure, what one can still express by saying that the form emerges or is immersed in the ET structure: how did the Ancients see the forms? - the Ancients being the Greeks, Egyptians, Hebrews, Sumerians, Chinese 6000 years ago, or even the Toltecs, Aztecs, Mayas, Incas... finally the Pre-Columbians, or the Eskimos, the Aborigines of Australia, etc.. They perhaps did not see them as modern man, that of the civilization in which we live and which we will name "Rational Civilization" or "Rational Coherence Field". For example, were the Egyptian pyramids - Cheops - seen 3500 years ago as they are now? It seems that denial is the answer to this question! The new concepts developed by the ARK'ALL group, then the DECALUM association and the EUREK'ALL® company as well as the ARKOLOGIE association are on this path. We must not delude ourselves about the concept of progress often used in our society, this progress that results from the superiority of the present compared to the past from the point of view of knowledge, technology, attitude, etc... It is not like this must be reasoned because past civilizations were undoubtedly quite different from what rational thought can describe about them. To absorb certain domains, one needs adequate thought and not to wallow in "the rational thought which can afford to approach any domain".

So to look at bas-reliefs on walls and monuments and to describe them is simply to force them into the Field of Rational Coherence (C. de C.

for Field of Coherence) when they are not adapted to him - the rational C. de C. only deforms them as one deforms a hat that one wants to fit into a box too small for him. We can only hope, in the case of the hat, that after coming out of the box it will return to its original shape. Whereas the bas-reliefs are totally deformed if one is not aware of the existence of another thought than the usual (rational) C. de C. This other thought is called “ *Other Coherence Field* ” or “ *Dynamic Coherence Field* ”. In the other C. de C., the bas-reliefs, ancient monuments, ancient languages, ancient history and legends, will give their true meaning.

We can ask ourselves the question :

By postulating the existence of the Other C. of C., by building it little by little, is that enough to be sure that we catch up with the thought of the Ancients, or the Thoughts of the Ancients? It seems that the answer is positive when one discovers the operability of certain found or manufactured forms! But it is still necessary to take into account the fact that these forms are going to be in the rational representation of the ET, all that constitutes a representation, which is certainly not those of the /Anciens. So we can cause transfers between the form of the present and the more or less distant past.

Thought has this good thing: it can create the concept that allows access from one knowledge to another unrelated to the first. It is therefore the “Transfer”. The world is a creation of the brain; at the same time as the brain imagines, the observer is immersed, diluted in its construction. The process is not rational <sup>3</sup> even for the construction of the rational C. of C..

The transfer makes it possible to pass from the usual C. of C. to the other C. of C., forms like old alphabets contribute to facilitate the access to this knowledge, this feeling, this comprehension; moreover, there are multiple forms that allow this passage.

For the /Anciens, the forms were fundamental whereas in our modern world, they are consequences, functionalities for the realization of Technical Objects (OT) except when we are faced with Aesthetic Objects (EO) [4] and [14 ], [2], [3] and [15].

<sup>3</sup> See the works of Vladimir Rosgnilk, Jacques Ravatin and AM Branca

The Phenist Objects (OP) are made from delocalized functionalities. They correspond to most of the objects made by the Ancients.

Partially localized shapes can be used as landmarks. Every living being is a partially localized form, and even very little localized. Does every description lead to a landmark? One can always imagine an abstract space to which a form is associated. This abstract space is attached to the usual C. of C. by our presence in this C. of C.. form, they are fleeting.

What is very important is the concept of “necessity” [1], [2], [3], [4], [15].

It will not be developed in this first year course, like many other concepts.

But, as Léon Delpech wrote in the preface to [1], this approach which gradually emerges in this course "is not a game of thought nor a group attitude that wants to stand out or isolate itself, nor fruitless complications...this is a constructive step in understanding and new awareness. Nor is it a result of the crisis of rationalism, a vain escape, but much more the beginning of an emergence in human thought, an emergence that contains the thought of the Ancients... Researchers whose work is remained ignored by intolerance on the part of the rationalists or the fact that the technological society could not support their contributions, these being embarrassing for its stability, are highlighted in these courses. So there is JW Keely, N. Tesla, TH Moray, E. Hendershot, L. and MT Sprink, Coutelen, F. Dufourg, L. Rota, S. Bignand, G. Calligaris, G. Bergé, G. Lakhovsky, Enel, Prioré, A. Béchamp, L. Boutard, A. Morichini, D. Ghadiali, F. Crombette, W. Reich, H. Mayer, Geitel and Wilson, Abbé Fortin, Laithwait, H. Krayner, A. Schmidt , Mathias, T. Brown and many more... »

Creation is an ideal mirror  
that the Spirit presents to itself  
so that its beauty appears to it freely  
and as if from outside.

OV by L. Milosz

## Chapter II

### Shapes - Imprints - Delocalization

#### *I. Introduction*

One cannot find an exhaustive classification of the forms - in spite of that one develops here a particular type of forms called forms-imprints. There are 3 that are fundamental. The first 2, which will be presented here, make it possible to establish the so-called Eifs at the EFF level.

#### *II. Heuristic presentation*

It was discovered by Enel researchers (Prince Skariatine) around the 1920s, then pursued by Chaumery, Bélizal, Lafforest, La Foye, then by Ravatin, Pagot, ..., sorts of emissions related to colors, shapes .

These are not electromagnetic waves as researchers initially believed. Here we come across existence without landmarks, these "waves of form" as Enel called them around the 1920s are linked to the *Global*. We are therefore not faced with a phenomenon linked to a rational process but at the entrance into an immense domain that is existence without landmarks.

A completely delocalized form emits a lot of these "emissions" which we have called "EIFS <sup>4</sup>" for each.

One can also find these kinds of eifs... which are not linked to the shape but to the mass <sup>5</sup> . They are called EIMS. We will not study them in this course. You can go from eifs to eims and vice versa.

One can still wonder if there are such entities that are related to both form and mass. This only finds mixtures of eifs and eims.

<sup>4</sup> EIF: E for emergence, I for influence, F for form, plural Eifs

<sup>5</sup> This was established by Pierre de Montgrand

We are therefore going to consider the first 2 shape-imprints <sup>6</sup>. They will be placed vertically. They make it possible to detect the eifs discovered by Enel, called "color eifs" or by abbreviation "colors" because they were discovered from blue, green, yellow, red rags... Other "colors" had to be added, which are not, like white, black, infra-red, ultra-violet. We therefore speak of the "color" spectrum.

We have tried to build this spectrum of "colors" differently, so as to justify this supplement which is not, if not inspired by the electromagnetic spectrum, in the visible part of this spectrum.

This is where the first two form-imprints come in.

### ///. Forms-imprints and eifs

It should be remembered that what is detected in this domain is not found there, in our usual field of coherence, since it is linked to the *Global* ; on the other hand, the effects occur in

**Figure 1**

certain places. We can say that the structure AND serves as a support. But will it still serve as support for another reality that does not concern her? It may not! At that time (if we can say so), we will have phenomena which can not be detected in any way, which would have an existence linked to the *Global* and perhaps even to something else that we will not develop here [15] . The human being will then have to imagine a support other than the ET structure and, if no support presents itself,

Let's see the first imprinted shape: we consider a circle with center O and radius OA. On this circle, let's place the points B, C, D such that  $AOB = 75^\circ$ ; C is diametrically opposed to A;  $DOC = 30^\circ$ . We can

<sup>6</sup>We gave them this name because they appear like footprints in a plan.

**Figure!**

iei

extend OC outside the circle. The shape thus described without the circle is called shape

-

imprint of the first kind (figure 1).

Consider a circle with center O and radius OA. Points B, C, D, E, F are on the circle, such that  $AOB = FOA = EOF = 30^\circ$  (Figure 2)

$$DOE = 50^\circ$$

C is diametrically opposed to A

We can extend OC outside the circle.

These two forms (from the et 2<sup>ème</sup> espèce)

can be placed in

vertical planes, the point A will then be considered the highest and AC is perpendicular to the horizontal plane.

We will use them like this.

Consider a semicircle and a diameter MN in a horizontal plane. Let K such that  $MKN = 40^\circ$  and trace KM and KN.

Let us plant in K the imprinted form of the first kind, vertically. It is in the vertical plane of trace OK on the horizontal plane (see figure 4).

This gives the eifs (figure 6).

But we can keep only the horizontal flat shape and plant in K, the shape -imprint of the second kind, vertically, entirely in the same plane as before, with a KO trace (see figure 5).

We detect a new eif vertically from A, O, C that we write V and the

We thus arrive at 8 eifs. These are the “colors”.

**Figure 3**

**Figure 4**

**Figure 5**

Reminder : in the works of Enel the "colors" were placed on a circle and to the green to which it corresponds the  $V^+$ , was diametrically opposed an eif which was written V.

This is the one we found in this montage. Thanks to this new eif we will bring up new ones listed by Enel, Chaumery, Bélizal, Lafforest, La Foye: IR, BC, N, UVi. These no longer correspond to colors but in this spectrum they keep this denomination.

We will keep it.

**Figure 8**

To make these 4 news appear, you have to take the figure above, always in a horizontal plane: you draw the complete circle. We send in K some  $V''$ . We detect the 7 eifs previously found, the  $V'$  diametrically opposed to  $V^+$ , as well as IR, BC, N, UVi.

In summary: we found 12 eifs.

## Exercises

- 1) Build these imprinted forms of lie and 2nd kind.
- 2) Detect so-called undifferentiated spectrum eifs; naturally it is not a question of determining the eif specified by its name, that will be seen later. We will only search for eifs.

## *IV. Supplement to Chapter II*

### Detection of eifs

These eifs must be detected.

They are not electromagnetic waves as some have believed; they thought they were in the electromagnetic spectrum, either below the hard y-rays or above the Hertzian waves. Below the y are the hard y and beyond the hertzian waves, the ultra-hertzian waves.

There have been multiple approaches to this field; we thought in the way of Enel and those who more or less followed him: Chaumeray, Bélizal, Chaisemartin, Lafforest, La Foye, Pagot, Philippe, and even the researchers of ARK'ALL and those of ARKOLOGY, by BARKA; the way of Morel was slightly different on what is detected on the forms, then there was that of Béasse and still many others like that of the Servranx brothers.

We realize that the form is not apprehended in the same way by everyone and that if we do not attach ourselves to a school, we will describe a form by its "emissions" in very different ways.

So, we can say that by this remark, we are not dealing with electromagnetic waves; ditto for sound waves or more generally any type of wave.

We have therefore entered a domain where we no longer measure and yet there is existence.

It is the existence without landmarks, linked to the *Global*.

The eifs are linked to the *Global*.

To detect them, you will need:

or measure the phenomena linked to the *Local*, they are because they are an integral part of our rational world, the usual local.

either use mancies.

Why the mazes? ! : they seem as old as the world.

Pendulum, rod, throwing stones, flocks of birds, interpretation of signs etc... function in the sense that they give information because the observer forces himself to redo his cerebral process.

The human brain works in wandering and finds itself faced with the unexpected: by this process it “discovers”. That is to say, it extirpates from itself what is potentially existing. The human being, the observer <sup>7</sup>, is not only what we think of in the usual C. de C., but he is largely undetectable and this is how mancia takes on its value.

### Some tips

In research by mancies, phenomena are triggered - which vary according to the person - and make it possible to work, in certain cases without tools - rod, pendulum, etc... -. Extra-sensory means are placed which are odors, tastes in the mouth, sensation of wet feet with the passage of currents of water, indefinable sensations on certain parts of the body and even sometimes painful sensations, a muscular reflex.

The practice of the pendulum is called pallomancy. This term has been forgotten for dowsing which is there to remind us that we are linked to phenomena close to radiation when it is not that at all.

Rhabdomancy is clairvoyance using the wand. It is assumed, by analogy with rational vision, that between two points, if information from one is found in the other, something is detected between the two. Thus, in the area that concerns us, statements such as: “objects radiate”, “emit”, “this place is charged”, are frequent and unfounded statements.

<sup>7</sup> In the works of Vladimir Rosgnilk, then of Jacques Ravatin then in the work to be published by J. Ravatin and AM Branca "Theory of Forms and Fields of Coherence", the word observer is replaced by that of obs which is more general than that of an observer as we discover it in physics.

These ideas have only served to establish pseudo-theories and directed experiments which Q limit themselves by the principle mentioned.

In our society, we know the effect of inert objects like the refrigerator which emits infrared radiation, a television set X-rays on the sides. They create influence around them often from a great distance.

But electromagnetic radiation should not be imposed wherever there is influence. This radiation is perfectly described by Maxwell's equations.

Regarding objects, forms, effects are actually felt, are perceived by sensitive people - fortunately there remain some in the rational world - from the object, or even far from the object, without any link between the object and a place, or another form.

It should be noted that the volume of influence has nothing to do with that of the object, sometimes it seems to be linked to its mass but again, there are many exceptions.

Let's see the example of the empty glass, placed on a table without a drawer, alone on the table and in the center if the foot is not central. A special eif is detected in the axis of symmetry of the glass above the table and above, but it can happen that the eif (which, as we will see later, is a VE) is detected in the horizontal plane of the surface of the table. Naturally, only an investigation by mancy or direct clairvoyance will confirm this.

The rationalists sought to explain the dowsing act by excitation of the brain in connection with these famous radiations from where nervous control leading to a muscular reflex determining the gyration of the pendulum or the rotation of the rod.

Experiments show that it is quite different.

The Baron de Reichenbach who lived in his castle in Germany until around 1865 had set up, among other things, the following experiment:

<sup>8</sup> Private communication from J. Pagot to J. Ravatin

After a while the pendulum moves. You have to understand that the technical pendulum object - a wire with a weight at the end - is no longer quite that; we will say that it has partially delocalized, which means that the criteria that usually establish physics are no longer completely valid.

The same goes for the stick: even with little training, you realize that the movement of the stick is not due to a muscular reflex aimed at rotation. The rod rotates 100 to 180° while the clenched hands oppose the movement, so much so that in these conditions the rod breaks. You can make a fork with dry grass, bend it in a V. Being very flexible, it does not turn but bends downwards, a movement impossible by muscular action of the hands. We can also take 2 springs linked at one end and held at the other, placed in a V, point down. This V, too heavy and too soft, must be held vertically. When you pass, with a mental convention on an underground watercourse, the V-shaped tip rises forwards or backwards which is impossible to achieve by muscular action.

If the wand rises, he comes to the idea of involving a vertical force which acts from bottom to top on the wand. But during its movement, this instrument is no longer a technical object; one cannot reason about it as one does for the objects described in the rational world. Gravity no longer seems to act in the same way in the case of the levitations of objects or human beings. Indeed other characteristics appear on these objects and human beings which show that their relocation is accentuated. Measurement processes hardly work anymore. And want them

imposing is not enough to observe the phenomenon correctly; this can disrupt the unfolding story <sup>9</sup>.

About the levitations of objects and human beings, it happens much more frequently than is known, the RBB <sup>10</sup> not wanting facts to get in the way of the few assumptions they learned in school, postulates that serve them to hum a partial knowledge, which they want to be total.

When we write partial knowledge it is naturally a question of knowledge coming from rational thought which for them is the one and only form of adequate thought to approach the world. They do not understand that thought creates the world and therefore, depending on the chosen field of coherence, the world built will be different.

<sup>9</sup> Yves Rocard, in his book “Le signal du Sourcier” attempted to prove, with supporting experiments, a completely rational explanation of the pendulum effect. There he describes experiments proving the action of a weak magnetic field on muscular reflexes. He absolutely did not believe in the possibility of working from a plan; yet it works very well; then the explanations of this little book collapse. Moreover in this book it is denied the possibility of detecting still water because water must move in the earth's magnetic field. But we must congratulate Y. Rocard for having had the courage to discuss this subject in the scientific entourage that was his. Besides, this book is not for everyone!

<sup>10</sup> RBB: Stupid and Stupid Rationalist. Not all rationalists are RBBs, but in our time many of them have become. And this in the name of Science, which they invoke as a fearful little boy wants to scare people by calling on his big brother for help.

He who feels that his own life  
and that of his fellow  
men is meaningless  
is not only unhappy,  
but he is barely able to live.

A. Einstein

## Chapter III

### Eifs at EFF level

#### */1. Rules of caution*

The eifs which have just been presented are said by J. de La Foÿe to constitute the undifferentiated spectrum.

They will be detected by a mania:

- pendulum,
- rod made of various materials, however they must be flexible.
- Lecher antenna.

You can also use direct clairvoyance, without an instrument. This is the fastest method.

It remains that whatever the method chosen for detection, the question must be asked very well to avoid any ambiguity. We must also not forget the representation chosen by the observer. Excellent researchers do not agree on what appears to be the same test because they do not have the same concepts in mind, nor the same arrangement of these concepts, nor the same meaning associated with these concepts, nor the same stories attached to these concepts, which goes into what is called tacit knowledge.

It is necessary to get into the habit, in this domain, of probing one's tacit knowledge. This should, moreover, be done in the rational domain; this would lead many researchers to question the basic assumptions of the scientific world.

You have to learn to detect these eifs.

We will start to simply detect an eif on a set of eifs without trying to bring them back to this spectrum.

For this we use flat shapes or volumes. Care must be taken when using flat shapes, for example drawn on a sheet of paper,

- so that the sheet has no lines,

- the position of the sheet relative to the observer, which places the shape.

The observer must realize that he imposes by habit, his tacit knowledge, an orientation: we say the top of the sheet, the bottom of the sheet...

This is in reality, what we will see later, what J. de La Foye called the “North of form”.

Some forms are sensitive to an orientation, to a neighborhood, the neighborhood can even extend to the positions of satellites (Moon), planets, sun, constellations. We know the effects of the Moon on the growth of plants: we can put this on the cause of certain eifs if the chosen representation wants it to be justifiable only by eifs, we will therefore find a justification by the eifs linked to the phases of the moon.

A model based on such a representation is not rich enough. We must then reflect on what the Moon is,

what it means.

We can represent it as a satellite with its movement around the earth, that is to say, starting from a usual, rational representation, in which we add its light and eifs which are absolutely not elements of rational thought.

We can imagine it as a form which could even be considered flat, moving on the dark background of the sky, like a window in the sky, with associated eifs - the questions of gravitation absolutely not intervening except for the vertical of the place in a pinch - the Ancients must have used such a representation.

We can associate an entity with it which will come into existence because other entities are attached to other stars. These entities belong to the kingdom of the living. It is the set of associated entities that makes each one exist. To a set of forms we make correspond a set of entities. These entities interact with each other and also with the shapes. Animists follow this path.

A question then arises: which representations will choose the cultures subjected to the light of the moon, or even more, to the presence of the moon?

The observer will therefore choose his model in a representation and will thus explain the effect of the moon on the plants. We are not going to talk about one explanation truer than another but about explanations that are richer than others.

In the Dordogne, 35,000 years ago, the human beings living in these regions had other representations which were operative at their time; they may not be now.

### Planar shapes

Back to planar shapes; they are more delicate to handle than the shapes in volume because they intervene in more diverse representations than the other shapes, for example icons.

There is a cerebral path to take to approach an icon, unless you understand what the icon is. If this path is not respected, the icon will remain a shape in a flat surface which can be tested for its associated colors and eifs. We see that even if someone is informed about this unorthodox field, his ignorance of many concepts which do not belong to the usual C. de C. will mean that he cannot test the icon correctly - We are of course talking about the real ones icons. Modern icons or copies of icons absolutely do not have these properties - . We can work on flat shapes to practice. But you will have to be very careful about what you are looking for: for example, if you place 3 points in a plane and you are looking for the eifs then coming out of the plane, you will not have to represent a triangle if they are not not aligned, a straight line if they are aligned.

Remember that when we speak of eif in a given place, especially of a given form, it is an excess of language, the eif not being identifiable. Simply the effects are detected there.

### Volume shapes

It will be to your advantage to begin training on forms with cylindrical symmetry: reel, drinking glass, carafe without handle or spout, vase, etc... Place the form on a table without a drawer, free of any object. Avoid a table with a central leg and place the shape to be studied in the center.

Then we will move on to forms: cubic, spherical, etc... then to shapeless forms and then to systems of forms. By varying the arrangement of each part in the system, one arrives at enormous possibilities.

## *II. Dowsing*

The experiments carried out in parapsychology, the domain of forms, incomprehensible healings, and much else, tend to set up a world which is not at all that described by the rational C. de C..

Unfortunately, people contrive to return to this C. de C. which is not adequate for the understanding of these phenomena.

So it is with dowsing.

It is used in a binary way - especially when the person who practices it is just starting out -.

That is, the pendulum oscillates or rotates <sup>1</sup>.

We have one and only one answer to a clear question. There must be no ambiguity in the question, no hesitation in the expression of its wording. For example, we will not say "is he okay?" », but « he goes! and the answer will be yes or no.

In the "does" an indeterminacy exists that can be found in the answer.

So we throw the pendulum swinging, we ask the question. If the answer is no, it will continue to oscillate; if the answer is yes, it will turn one way or the other.

The direction of rotation may be levorotatory or dextrorotatory. This makes it possible to impose one more condition. We leave it to the reader to find his own.

## **The world is not Cartesian**

We know the effectiveness of analytical science with respect to all that is artificial since precisely most of the constructions made by man come under this concept of analysis.

We like to have systems like technical objects: a motor turns or it doesn't. If it does not turn, for example for that of an automobile, it is

<sup>1</sup> We will not consider the case where we place the pendulum at rest and wait for it to move. It is often long and certain external conditions can be troublesome.

there is no more fuel or there is a fault. Troubleshooting is self-directed.

A gear turns in one direction or the other, etc.

They are binary systems. Not all are binary. But Cartesian reasoning removes the ambiguity. Life does not correspond to Cartesian systems. The usual Coherence Field models that want this are seriously mistaken.

To imbue your model with what was inspired to set up all the tools is to pollute Life.

### *HI. Exercises*

#### Planar shapes

- A circle is traced on a flat white sheet without pointing to its center. We detect in the center of the eifs.
- Likewise a square, likewise a regular convex or star polygon.

To think that we have tacitly oriented the sheet by its position with the top and the bottom, which orients the shapes drawn.

#### Volume forms

- We take a glass with cylindrical symmetry that we put on a table that does not have a drawer. It is not placed above a leg of the table.
- Check that an eif is detected on the lens axis, above and below the table.
- Sometimes we detect one in the plane of the table, check it.

#### Tips :

1. This axis or this plane can extend over a few decimeters or meters, without us being able to know it a priori. Only a mantic detection will tell.

There will be cases where on the axis above a certain distance nothing is detected. It is necessary to check always further on this axis; one can detect again further.

2. In dowsing you have to be passive, or better, available, let the answer come.

You have to be as if you had all the libraries in the world in your head and you let yourself go and find the book, the page, the paragraph where the answer is. We are confident.

However, there comes an answer that seems wrong. You must not admit defeat. It may be a good answer but the question was badly posed or it may come from the tangle of concrete situations that our lack of experience does not allow us to suspect.

Exercise : we practice looking for objects.

For that I take 5 envelopes and I put a postage stamp in one of the envelopes. Find the stamp?

1. Mix 5 envelopes.
2. Take a pendulum or a rod in order to find the stamp: do not forget the mental conventions.

I throw the pendulum in oscillation in a plane.

When the answer is positive, it will start rotating (regardless of the direction of rotation).

Corrected :

- we find the stamp.
- the stamp cannot be found - it is possible that we pass above the correct envelope, the one which contains the stamp, but that we do not pass above the stamp -.

So we modify the question: find the envelope that contains the stamp.

When we have found it, we will begin a similar experiment. We see that there is a sequence to respect.

- Do not forget that we hid, we intended to hide. This, in the test, can adversely affect the appearance of a positive response. Beware of games.
- If you don't like the game, don't provoke the game.

So do not have an approximate, poorly formulated question.

We call back because it's important: “ Do not say, do you ? In this expression there is already an indeterminacy that can be found linked to the answer and it will then be indeterminate, which will lead to discouragement.

Be wary of the advice of other people, even other dowzers, it depends on their culture, on what they represent. For example in front of "613" an operator will say "digit", or "digits" or number. In fact it is a number made up of digits. Then there is the tacit knowledge already mentioned. 613 for a Kabbalah enthusiast will bring to mind the 613 commandments in the background.

Then notions, although precise, are used inappropriately in everyday language; for example pressure, force, tension are used one in place of the other.

In this domain that we are dealing with, it is not because the landmarks are variable, that we have existence without landmarks, that we must speak of vagueness and drown in vagueness. On the contrary, it requires great rigor.

Then if a detection exercise is repeated too often, for a beginner, it can happen to errors.

Exercise: we throw a dice under a handkerchief, the figures that come out are

1) look for what comes out?

### Advice

- If you find the correct result, don't say to yourself: I had a chance in 6 of finding the result.
- If we start again not to say to ourselves it is the 5 that came out, there is little chance that it will still be the 5. We fall back into a rational approach and the dowsing is not.
- A person says to the operator "I challenge you to find such an object" What to do?

Advice :

- don't take up the challenge.
- any failure or semi-success is immediately held against the operator. We have N possibilities in front of an action; what about the test on the N possibilities?

Advice: be careful because it may happen that the positive answer is not in the N possibilities, and then if we have the preconceived idea that it is in all the N possibilities, we will find one for sure.

We must therefore think carefully about what we have present in its representation when we begin to test.

2) *The operator is presented with 6 eggs, one of which is in plaster, and is asked the sex of the chicks to be born. What to do ?*

Tip: do nothing because the problem is skewed. We can very well pass over the plaster egg and give the sex of a chick since we are adopting the story of the one who chose the eggs.

#### *IV. Differentiated and undifferentiated spectra*

Another spectrum has been discovered: the differentiated spectrum.

The eifs of the undifferentiated spectrum are not at all those of the differentiated spectrum. If we look closely, we realize that Enel had already spoken of the differentiated spectrum without naming it.

Differentiated and undifferentiated spectrum eifs have been used to heal.

We will see the implementation of these spectra in the next chapters as well as the completion of these spectra of eifs.

The differentiated spectrum was discovered by Enel then taken up by J. de la Foÿe, R. de Lafforest, Chaumerey, Bélizal. Nevertheless the first presentation, that of Enel, was not completely followed by those who were inspired by it.

<sup>2</sup> Colonel de Rochas, deputy director of the Ecole Polytechnique until 1905 had discovered 2 “rays”, one red and one blue. He could restore certain dysfunctions of the human body by playing on one or the other. Enel knew C. de Rochas personally and worked under his direction until 1904

## Chapter IV

# The Eifs - Full spectra

*/. The complement of the undifferentiated spectrum*

We have seen that the eifs are distributed over a circle which can be opened and extended along a line segment; Which give :

V<sup>+</sup> JOR IR NV Bc UVi In Bu V<sup>+</sup>

[illegible]

Between two “colors”, for example O and R, are all the points of the interval  $O \in \mathbb{E} \in R$ . The segment is divided into 12 parts of equal length.

The presence of the 12 colors makes it possible to associate new eifs with each of these points.

We will say that the model of the undifferentiated spectrum has an extension. This was used by Jean de la Foÿe.

Thus we will detect:

- or colors that appear as lines on the diagram: e.g. J, V', Bu.

V + JOR IR N V' Bc UVi In Bu V +

```
LLLLLLLLLLLLLL| LLLLLLLLLLLLSS^JSSSSSSSSSSSSL|N|NSSSSSLSSSSS
```

- or lines that are inside an interval: e.g. that of the OLLLLLR

those

I ban

ViLLLLLLIn

AB

- either bands: e.g. NLLLLLV" that is to say that in this case we detect in  $A$ .

and B and all that is found in the interval AUUB The entire spectrum will be said to be an undifferentiated continuous spectrum .

## H. The tree trunk

Suppose we are testing the trunk of an almost cylindrical tree. Let  $R$  be the radius of this trunk. The trunk is vertical; by thought one cuts through a horizontal plane.

On the trunk, in this plane, one can detect the 12 colors and the entire undifferentiated spectrum.

But Jean de la Foÿe found on a concentric circle, of radius  $2R$ , something else <sup>3</sup>.

These are new eifs.

These eifs had been discovered by Enel. He had attempted a rapprochement with magnetism (M) and electricity (E). So there were M-type eifs and E-type eifs.

He had split the undifferentiated color spectrum into 2 spectra, one M-type and the other E-type.

Thus we found:

|                |   |   |   |    |   |   |    |     |    |    |    |    |        |
|----------------|---|---|---|----|---|---|----|-----|----|----|----|----|--------|
| V <sup>+</sup> | J | O | R | IR | N | V | Bc | UVi | Vi | In | Bu | V* | type M |
| V <sup>+</sup> | J | O | R | IR | N | V | Bc | UVi | Vi | In | Bu | V* | type E |

for example on aura BUM, RM, V<sup>+</sup>M, V'M

et on aura BUE, RE, V<sup>+</sup>E, V'E

This means that we have 2 spectra and the whole will be called a differentiated spectrum.

Jean de la Foÿe had supposed that any color of the undifferentiated spectrum was composed of 2 colors of the differentiated spectrum of the same name but of type M and type E; for example :

- Bu would be composed of BUM, BUE
- V<sup>+</sup> would be composed of V<sup>+</sup>M, V<sup>+</sup>E
- V\* would be composed of V'M, V'E etc...

<sup>3</sup> Nothing will be found on circles of radius  $3R$ ,  $4R$  etc... nor on intermediate circles.

That's a bit of a strong assumption. If we have this idea a priori, by testing out of fear, we will indeed find confirmation of this hypothesis.

Tip : If we use a mancy to find an answer to a question, we don't have that answer. But we must not have a small idea otherwise the result will be directed and therefore the answer will be false. This is the great difficulty, we must let the answer come.

Gradually we will move on to mental conventions associated with abstract ideas but at the beginning, we must ask clear questions which will allow quick and unequivocal answers.

Exercise 1 : Either to find a cure for a sick person. We have the list of remedies of a given range or the box of witnesses.

- 1) In mancy we will use the pendulum. What do we do ?
- 2) We throw the pendulum in oscillation, what do we think?
- 3) We move on to the second remedy, the pendulum swings, what do we think?
- 4) For 4 remedies, it is the same, should we deduce that the 4 remedies are good?
- 5) What conclusion can be drawn from such a test?

Solution : see end of chapter.

Notes :

- 1) Avoid starting the dowsing operation with the pendulum stopped.
- 2) By excess of honesty certain beginners try hard, especially vis-a-vis the RBB, to maintain the motionless pendulum for fear of being accused of persons in charge for the movement.

This attitude makes no sense because:

- the operator by tiredness makes move the pendulum; it starts with small movements.
- wanting to maintain the immobility of the pendulum leads to keeping it immobile so there is no response.

- The baron of Reichenbach in the 2<sup>nd</sup> half of the XIX<sup>th</sup> century made an experiment which tends to show that the motionless pendulum takes a movement after a more or less long time when it is linked to an observer. This experiment will not be described here but it is reported in Fascicle 1.

- 3) It is necessary that, in the case of the pendulum, the hand and the wrist are free and flexible.
- 4) The pendulum must be kept short, the answers are thus quicker.
- 5) Authors and not the least have associated specific lengths with the wire of the pendulum and even on the wire have placed knots affirming that these correspond to very precise conditions. It is not so. It is simply due to mental conventions that were not seen as such by their creators.
- 6) The weight of the pendulum: 8 g. at 70g.
- 7) The rod can advantageously replace the pendulum outside when it is windy.
- 8) About the wand the simplest method is perhaps this one:

By mental convention, it is accepted that the rod dives when the tip of the foot crosses a sought limit, for example, a trickle of underground water. We can then slide the foot on the ground to refine.

But you have to think about this: everything depends on the representation you have of groundwater: if it flows in a rocky corridor or in a pipe, you will have lines on the surface that will be clear. Otherwise, there may be muddy or sandy areas close to the water trickle, filled with water resulting in a weak line.

net.

Exercise 2 : We are looking for groundwater for a borehole.

- 1) What is the <sup>first</sup> question to ask?
- 2) Debit
- 3) Composition

Solution to exercise 1 and advice : The search for water is by far the best known application in rural areas. The medical dowsing represents today the field the most worked by the amateurs.

family                      [

Training from an agricultural point of view V is Veterinary <sup>daily</sup> J

Thus economy and health balance are always welcome.

Classical knowledge in human or veterinary medicine is not to be rejected but not always necessary, which often surprises the people of medicine because we will not make diagnoses of symptoms or diseases but diagnoses of therapies.

Solution of exercise 2 :

- 1) Look for the line vertically where there is a flow of water.  
See if moisture zone without flow.
- 2) Ask the question  $m^3/s$  or  $l/s$  in order to find the approximate value. Then after asking the question: between 1 and 2, 2 and 3 etc...
- 3) Mineral salts in significant quantities? Other impurities. Is the water drinkable ?

The attitude to adopt is that of the homeopath, that is to say, one seeks the remedy. So we often work on homeopathic remedies.

Do not dwell on people who claim not to have restorative effects with homeopathy. Their attitude blocks the possible effect. We find this in the case of the use of a mania about which some say: "With me it doesn't work! ! ". In this case, we must leave aside whoever says this because,

indeed, it will “never work with him” since he does not want it to work.

As some say “You can't work on a map because you won't detect anything on the piece of paper that makes up the map”. From the moment when they have decided that for them, posed that, they will find nothing. They impose the answer before waiting for the answer, they distort the process of research by mance. Mancy is therefore not for them.

Coming back to exercise 1, we must get out of the habit of thinking “diseases”.

What interests us is to find the remedy that the patient needs.

Thus one will seek with the pendulum, with the rod, or an antenna, which remedy one will need.

In homeopathy: we seek, in front of the patient, the remedy, then its dilution.

If several remedies are found, it is necessary to check if their combination is acceptable then the dilutions of each one.

### *///. Additions to Chapter IV*

In the field of forms often intervenes orientation, this one is sometimes in the tacit knowledge of the individual, by habit and training.

We saw this previously in the case of the orientation of the sheet of paper, placed on a table. The top corresponds to a tacitly implemented north. This north will be found more precisely in what follows.

Jean de la Foÿe had discovered this particular orientation to which many forms are attached. It is - he had named it thus - the north of form (NF).

Form North is 6° West of Magnetic North (NM) which, being about 5° West of True North, places Form North 11° West of Geographic North.

When Jean de la Foÿe spoke of certain eifs associated with certain forms, these forms - he did not specify - were oriented to NF.

It is necessary to be very careful when carrying out a work on the forms to determine the NF and this for each assembly, each experiment. Indeed, the NF changes according to the neighborhood. In a cellar, it happened to be found at 90° west of the NM, in other cases at about ten degrees east of the N.ML

And in the case of the sheet placed on a table, tacit knowledge put it on top according to the expression. The high and the low determine the NF.

We can impose this NF. It was Jean de la Foÿe who had also found the solution.

F We place 2 circles, one black, one white and we put the shape F between the two. The black circle imposes the NF. The centers of the two circles set up the ON.F. -SF axis.

This will be used in particular for the detection of the vital field which we will see later. Already Enel had pointed out - always in analogy with the electric current - that the conductive bodies and the insulators had different properties with respect to certain eifs. That was what had led him to the differentiated spectrum.

An eif of character M was, it seems, stopped by a magnetic body (iron, steel).

An E-character eif was stopped by an electrical insulator (bakelite, rubber).

Then Jean de la Foÿe had prepared the following assembly: it took 2 plates of the same shape, one in zinc, the other in copper - these are metals, therefore bodies that conduct electricity -.

He placed them vertically:

| Copper   |  | Zinc     |    |
|----------|--|----------|----|
| eif to E |  | eif to E |    |
| SF       |  |          | NC |
| eif to M |  | eif to M |    |
|          |  |          |    |
|          |  |          |    |

### Assembly 1

The axis of the system is the NF-SF.

We send according to the first assembly an eif<sup>sf</sup> in E and an eif in M, we detect after the copper an eif in E and an eif in M.

Zinc                      Copper

### Assembly 2

In this assembly, the copper and zinc plates are swapped.

Only the eif is detected at M.

In reality we still detect the eif at E but much further than the zinc plate.

This experience has only historical value, it will be considered as an exercise.

What you have to see from this is the process of the mind. The underlying idea is the electromagnetic spectrum. This domain of manies and forms is strongly influenced by analogies since it is the operator who sets up the representations. If some of these representations contain analogies or are directed by analogies,

answers that seem correct appear. The operator does not realize that he has chosen a model that is too poor.

Nor should we systematically reject all analogies.

This is where all the subtlety comes in, which makes for success.

Exercise 1 : The material to be used is made up of cylindrical glasses; five is a good idea.

We work on a table, in the center - the table must not have a central leg -.

We place a glass in the center of the table, the vertical axis

There is an eif on the x'x axis above the table and below.

Detect it - Here we do not have to specify the eif -.

What happens if you fill the glass at least halfway with a liquid? - water, oil -

The shape placed on the table is a glass. It can be replaced by a silver, cylindrical beaker.

What do we notice?

The glass is placed horizontally, with reference to the North-Magnetic-South-Magnetic axis.

What do we notice?

### New assembly

The 2 glasses are in contact.

Detection?

Are there variations related to the angle  $\alpha$ , between  $y'y$  and NM-SM?

Exercise 2 : We take the plane P and the lens with a vertical  $x'x$  axis

We place 4 glasses whose axes  $y'y$  and  $z'z$  intersect at O on the  $x'x$  axis,  $yy'$  and  $zz'$  are perpendicular.

there

Determine the places where eifs are detected.

### Answers exercises 1

- b) Nothing is detected above the table nor below in a region close to the glass; on the other hand, on this axis, we detect clearly more above P. We no longer detect anything below.
- c) The detection is done on the  $x'x$  axis of the lens over a much greater distance above above and below.

Notes :

- 1) the denser the material, the further away you can detect. Naturally, the proximity of the form also intervenes.
- 2) a detection taking place in a certain neighborhood around a shape F, when this neighborhood has been well delimited, it is not necessary to stop there. In fact, other regions of space that do not have common borders with this neighborhood can appear.

d) An eif - or eifs - is detected in all directions except one which is close to the

|                          |         |                                                               |
|--------------------------|---------|---------------------------------------------------------------|
|                          | i       | NM-SM.                                                        |
|                          | ;NM     |                                                               |
|                          | \ ;     | We will see in other chapters what is exactly this direction. |
| Direction where we X     | [       |                                                               |
| no longer detects___/    | X       |                                                               |
| nothing                  |         |                                                               |
| We will see later that   | ■ \     |                                                               |
| it is the one called the | j \     |                                                               |
| "North Form"             | j S.Nik |                                                               |

e) We no longer detect anything on x'x whatever the horizontal position of y'y.

On the other hand, eifs are detected on the y'y axis but nothing nor in y'y and in the North of shape-South of shape directions.

Answers exercises 2 : We detect along x'x but not along the 2 axes y'y and z'z.

The detection following x'x seems “stronger” than that in the previous exercise.

Note : This feeling of "stronger than" will be to remember. We can then fix a scale, for example, we will see in the following pages, from 0 to  $20^4$ . It will even be possible to have several values on this scale, that is to say a spectrum of values, discrete or of bands, which is richer than what measurements give for usual technical objects. But we will notice that we did not impose a scale a priori; it made itself felt, imposed itself little by little. This is how the concepts in this field are constructed.

<sup>4</sup> See the last remark at the end of this chapter

Tips:

- a) It is better for beginners, when doing these exercises, to work on a table rather than on the floor. Detections on a wooden floor - or close to the ceiling - are just as possible but the eifs are often "attenuated" in such assemblies.
- b) We will check that we detect the eif in the axis of the glass, under the table.
- c) We hold the pendulum in the right hand, we indicate with our left hand, the extended index finger, what we are looking for. Care is taken to ensure that the index does not interact with the phenomenon to be detected.
- d) If the glass is replaced by a coil, the detection is the same.

Note: When we are used to handling a pendulum or rod, we can immediately think about the problem, without moving, without indicating with our hand the very places where we must detect the effects of the eifs, the answers will come immediately.

Exercise 3: Consider a stemmed glass.

- a) What do we detect along the axis of symmetry  $x'x$ ?
- b) We work with a glass of the form

c) Other assembly

d) Same with an egg cup open at both ends

Answer exercise 3 :

a) We do not detect anything on the a  
symmetry on the other hand we de  
on the part indicated below

b) Detection along the axis and a little  
on the ends

- c) Detection along the axis. Nothing following the plane of symmetry.
- d) Detection along the axis and a little on the ends. Nothing following the plane of symmetry.

Note : If you put an egg in the egg cup, everything changes. It changes according to

that the egg shape is solid or hollow and the nature of the eifs will be linked to the fact that the egg

is real, artificial, solid, hollow, colored on the surface, etc.

- a) AB and  $x'x$  intersect at O. We rotate AB around O. What happens?
- b) If O is not on  $x'x$  what do we detect?
- c) We draw CD passing through O and perpendicular to AB. Detect the places where the eifs are detected.

Answer exercise 4 :

- a) In general, one or more eifs are detected along  $x'x$  - O is on  $x'x$  and AB -. On the other hand, if AB is following the North of Shape-South of Shape, nothing more is detected on  $x'x$ , nothing on AB or elsewhere.
- b) If O, which is on AB, is not on  $x'x$ , we detect in addition to eifs on  $x'x$  eifs in one of the half-planes delimited by AB.
- c) O is on AB and on  $y'y$  and  $z'z$ . We always detect on  $x'x$  but there is nothing if

the axis North of form-South of form is a bisector of the Cross of Saint-André formed by  $y'y$  and  $z'z$ .

Advice : About training in the manipulation of the pendulum and the rod you have to train:

- the 1<sup>st</sup> week  $V^*$  of hour per day
- the 2<sup>nd</sup> week  $V^2$  hour per *day*
- the 3<sup>rd</sup> week 0% hour per day
- the 4<sup>th</sup> week 1 hour per day
- and after, as long as you want.

This progression avoids getting upset.

A. about 300 hours of practice, we are sure of our answer if the questions are well asked.

Note : Sometimes we have a feeling of "more or less intense" about the eifs. It is a simple sensation, nevertheless it is useful.

Because the eifs are delocalized, therefore not identifiable, there is no intensity associated with the eifs.

We can try to place a scale equivalent to a scale of intensities but without unit.

So we will operate as follows.

Diagram imagined by André Philippe <sup>5</sup>

semi-circle and a diameter are traced on a sheet of paper, as well as 20 equal sectors numbered from 0 to 20. In the case of the eif - or eifs - detected on the axis of the cylindrical lens, we

<sup>5</sup> A. Philippe worked with Jean de la Foÿe .

a solid silver beaker, also cylindrical, placed in the same place; we are looking for the sector corresponding to the eif detected on the axis of the timpani - or the eifs

We find for example [9,10[ or [15,16[.

We will say that the eif associated with the timpani is of "intensity" greater than that detected on the glass.

It turns out that this scale is quite stable (this scale is reproduced at the end of the booklet on an isolated page in order to facilitate its use). But it should not be deduced from this that one can place such comparative scales on any manifestation of eifs or states - as we will see later -.

However, this is what many researchers in this field of forms happily and routinely practice. And they speak in addition to units: angstroms, centimeters, - units of lengths since they want to speak of waves and therefore of wavelengths -.

On such a diagram one can also place the vitality of an individual. We are going to "measure" the vitality.

It should be noted here again that the concept of vitality felt by each person cannot be compared on the basis of a unit. Different people can agree on the basis of this "vitality" on the state of health of a patient. So it still has a use.

#### Story from the comic strip Spirou:

Sometimes he passes on information in books, newspapers which seem innocuous but are very edifying or profound if you have the right frame of mind.

It should not be inferred that this message is intentional. Simply its author was, during the time of the creation of his work, more brilliant than he had ever been and perhaps he will never be again.

If we reflect on the point of view of the RBB on non-orthodox research, which they classify in the field of the irrational, therefore of debility, what is not measurable is nonsense, the result of phantasmagoria.

Fortunately it is not always so. And a form, an object have different functionalities according to the representation or the type of thought allowing to describe them, to use them.

In this short story (see end of the booklet) presented in the form of a comic strip, the child expresses in correct language what he extracts from the book. The Viking chief takes up what the child says, places it in his representation where it makes no sense since for him the book is not an instrument from which one can extract information. And indeed the chief asks a question which is not coherent with his personal representation. He falls into the absurd. This provokes laughter but the RBB laughs without knowing what he is laughing at. He laughs out of habit. The comic for him must contain a reason to laugh; even if he doesn't have access to the reason for the story, he still laughs. The story will thus have satisfied everyone!

#### ERRATA Fascicle 1 - year 1997

## Chapter V

### */1. Detection devices*

We will see later that certain forms, and living forms, require, for their eifs to be detected, states, what Jean de la Foÿe called an “artifice”.

For example, to test a potted plant, it is necessary for certain tests to lean the plant, for a tree to direct the left hand towards the tree, thumb folded over the little finger, the other three fingers stretched out.

For Jean de la Foÿe, the form seems to select or channel one or more eifs from the space surrounding the form. Space is thus, at every point, filled with potential possibilities.

This idea had been launched at the beginning of the century by Nicolas Tesla who said that energy could be drawn from any point in space.

Here it is not about energy but there is thus a double possibility: from each point of space one draws energy or one draws eifs, and perhaps from these eifs one can draw the energy?

Energy is measured, there are units: joules; erg. Eifs are not measured. Their effects are detected in certain places.

The form emerges or submerges in the AND structure. It is this process which is expressed by the eifs, by states. But completely emerged forms, for example a solid ball, a solid cube emit eifs in certain neighborhoods. What we detect is effectively linked to a neighborhood.

Can we find the neighborhood, describe it? Usually the answer is positive. We realize that this neighborhood is immersed in another, but the process is not recurrent; quickly the concept of neighborhood vanishes and we arrive at an emergence linked to the ball or cube shape.

### *he. Polarities*

One can associate to a form, to the forms or to a system of forms, polarities; it should not be confused with those of the magnet where in the rational thought are specified 2 poles therefore polarities, one for the north pole, one for the south pole.

Naturally, little or less of dowisers or "Ondiformists", when they heard about polarity on the subject of the forms, confused those of the magnets with any system that they tested and they added "They are indeed the same as those of the magnets since I find them identical".

There had crept in a profound error. If we have in mind that they are identical or of the same type, we will automatically find them identical.

So let's eliminate this error.

For this, consider two pendulums - easy to make in fairly dense plastic material, - cylindrical.

Polarity +

Polarity -

Suppose there are 2 strings, one fixed at O and the other at O'.

Note : it should not be said that by holding the pendulum by the string fixed at O or by the string fixed at O', the direction of rotation of the helix is changed. Remember that a right-handed screw remains right-handed no matter how you hold it.

So we really need two pendulums to define the polarities.

Exercise 1 : A human being has polarity + on the forehead and polarity - at the back of the head.

- a) check it
- b) what's on a statue of Easter Row? (cf. copy at the end of the booklet)
- c) Are there human beings for whom the polarities are reversed?

Answers

- b) There are no polarities
- c) the answer is positive. They are, as we will see later, often linked to harmful states.

Exercise 2 : We give ourselves a circle in a plane. We impose NF and SF as in the drawing.  
Find the polarities.

O

Exercise 3 :

- a) We give ourselves 3 tangent circles as below with the NF, find the polarities.

b) We give ourselves 3 circles as below. What can be said about polarities?

c) We give ourselves the 3 circles as below as well as the NF, SF.

#### Conseils

- 1) It is necessary to impose the NF because we will unknowingly give the answer in relation to the top of the sheet, which is a way of imposing the NF. But in this case the observer can move in relation to the sheet which may or may not change the result, whereas if the NF is imposed, the results are definitively fixed.
- 2) On the sheet where the figures are drawn, place the black and white dots imposing the NF, on the upper and lower edges, far enough from the figures so as not to disturb them.

#### Answer exercise 2 :

#### Answers exercise 3 :

- a) The interior of the circles is neutral. If we change the position of the NC, the polarities change. We can then test the following assertion: The polarities are a function of the position of the observer in relation to the form! The

position of the observer in relation to the form can be thought of differently: the form changes according to the position of the observer. It is the rational point of view which imposes the stability of the form in existence in relation to the observer.

b) Dans cette disposition, il n'y a plus de polarités

c)

Problem: We give ourselves a wooden disc, pierced right through in its center and a needle is centered in the hole

a) Study the polarities

- on the tray
- on the NFSF axis
- on the axis of the plate

b) Study the eifs

Corrected :

a)

b) Here at the SF we detect eifs; they correspond to the differentiated colors.

There is a  $40^\circ$  angle west of the NFSF axis which negates all polarities.

Jean de la Foÿe calls it the angle of equilibrium.

If  $2R$  is the radius of the disc, with a needle smaller than the previous one, i.e. with a radius slightly less than  $R$ , we do not detect a "polarized body"

### *HL The tree trunk*

Consider a tree with a vertical, cylindrical trunk. Let us cut the trunk of this tree by a horizontal plane.

Let  $R$  be the radius of the trunk.

Let's draw a concentric circle of radius  $2R$ .

---

<sup>1</sup> See the tree trunk

On the circles of radius  $R$  and  $2R$  we will detect eifs.

Let us immediately point out that we do not detect on circles of radius  $nR$  with  $n$  positive integer greater than 2.

The detection is done by artifice, for example the outstretched left hand, the fingers suitably placed - we described it previously Thus the spectra will appear on each of the circles.

It is good first to locate the NF.

Definition : We will say that the polarized body and the aura are virtual when an artifice is needed to detect

Then, let's find them:

- Circle of radius  $R$  : the undifferentiated spectrum is detected.

At NF we find the  $V^+$ , at SF the  $V$ , at OF the  $R$  and at the EF the  $V_i$ .

The other colors are arranged on the circle.

- Circle of radius  $2R$  : at NF we find the  $V^+E$

at the SF we find  $V^+M$

at the OF we find  $V'M$

at the EF we find  $VE$

In general tree trunks are not strictly cylindrical. What's going on ? We find the colors in the same order but they are no longer at equal angles. The diagram shows the polarities; the interior of the circle of radius  $R$  is neutral.

The part between the 2 circles has positive and negative polarities, likewise the outside of this circle.

Exercise 1 : Consider 2 solenoids: one whose direction of rotation is that of the positive helix in paragraph II on the polarities, another like the negative helix presented in this same paragraph.

We send an eif along the x'x axis.

Consider the positive helix :

Check that if we send an eif in M along x'x, it stays in M. If we send an eif in E along x'x, it stays in E.

There is conservation of the eif.

Consider the negative helix :

Check that if we send an eif in M along x'x, it goes to E and an eif in E, it goes to M.

Everything happens as if we made a symmetry on the tree trunk in relation to the center.

Exercise 2 : We start with a candle that we light.

1. Check that we have a polarized body and an aura if the candle is lit and that the polarized body is virtual
2. Check that if the candle is extinguished, nothing is detected even with artifice.

Exercise 3 :

- a) We take a crystallizer in which we pour a solution of soda then a solution of sulfuric acid.
  - Check that we detect a polarized body and an aura around the crystallizer, both real, so there is no trick to put in place to detect
  - When the reaction is complete, check that nothing is detected.

Reminder : The reaction is:

- b) We start from a crystallizer in which we always pour a soda solution but second we pour acetic acid
  - Check that we detect as before without artifice a polarized body and a real aura.
  - Check that the polarized body and the aura are detected all the time; this must be related to the fact that the reaction is balanced.

Reminder : The balanced reaction:  $\text{CH}_3\text{COOH} + \text{OHNa} \rightleftharpoons \text{CH}_3\text{COONa} + \text{H}_2\text{O}$

Course for “Title” “Name”

“All doctrine goes through three stages.

We attack it first by finding it absurd.

Then we admit that it is true but insignificant.

Finally we recognize its true value and  
its adversaries claim the honor of having discovered it.

August Light

#### IV. A few clocks

To detect the polarities 2 pendulums are necessary. We start with a cylinder with a diameter of that of a broomstick.

-- ---^Length: 4cm

And we trace on a rectangle of paper ABCD which will cover the cylinder the segments AJ and IC then IB and JD.

I and J being the respective midpoints of AD and BC.

We thus have each helix.

If we start from pieces of broom handle, which are made of wood, we must draw on the upper face of the cylinder 2 parallel lines which remove the polarity of the wood because

morceau de bois a une polarité.

These two clocks were designed by Jean de la Foÿe.

Another was developed by Raymond Montercy. It also gives the polarities.

The advantage over the previous ones is that there is only one.

### Pendulums of the polarities of Jean de la Liver

### Polarity pendulum by Raymond Montery

The string crosses the sphere from side to side, which means that it can be knocked over. In this position, the + at the top, we detect the + polarity and

*V. A few comments*

- 1) The stones in the countryside have polarities, the pieces of rock the same. This can be used to rebalance the places; for example a house which has harmful eifs can be made pleasantly habitable by placing stones in the garden of this house; we look for the polarities of the stones and we arrange them in relation to each other.
- 2) When you place the first stone, you must already have found out how many it will take, maybe 2, 3... And place the first stone knowing that you will have to place 2, 3...
- 3) When all the stones are in place, we will check how things are going in the house, if it corresponds to what we wanted.
- 4) You have to ask yourself the question of what will happen in the following days, the following month; in fact, this reinstatement shakes up an established order; there may be repercussions.
- 5) But we don't easily rebalance only with stones
- 6) We know that we are in a domain that is not rational. We started from the concept of polarity which involves our world of duality. Suppose we are talking about polarity without imposing a dualistic view.

So we can find shapes with one polarity and more than 2 polarities. We discovered such shapes with positive or negative polarity, with one negative and 2 positive etc...

The study of forms contains many surprises; one discovers some especially if one does not impose too much the rational diagrams.

## VI. *Some tips*

- 1) In dowsing we will notice certain particular points: those where two streams of water cross - in vertical projection on the ground because they are not necessarily at the same level -, At these points it happens that pendulums and rods react differently, as if one wanted to point out a peculiarity to the manipulator, and it is one!

We also have another particularity, it is a point on the ground where vertically there is a rise of water presenting a pressure from bottom to top.

These points can be life-threatening; a “strong” V'E IS DETECTED ; and another thing that we will see later: this is called the “Knot of Life”.

- 2) The mancies, in particular the dowsing, are without limit. Thus, after having detected the water current, the favorable point for drilling, the depth, one can look for the flow rate, the temperature, the mineral salt content, the pH and the variation of these properties with the seasons, etc... Thus we can look for any physical or chemical parameter that we imagine.

Let us not forget that this research can only be carried out successfully following training and also it is necessary to point out a specialization. Thus some become specialists in the search for lost objects, they have astonishing successes; others specialize in breakdowns of various devices such as television sets; for still others it is groundwater detection

Naturally all these people have the “language of the dowser”. They try or don't try to explain what they are doing; the best is that they leave aside any attempt at explanation, what counts is the success and often they are valid.

- 3) The search for water can be a training theme for beginners unless they work with a professional dowser whose detections are always followed by drilling, otherwise you never know if you have found the right answer.

So we'll practice finding the depth of water in an existing well. We control afterwards with a weighted string.

Then we will look for the currents feeding the well. We will reproduce the whole according to a drawing on a sheet of paper and we will see if on these currents found do not

find no other wells.

We will see if houses are built on these currents, if they have cracks.

We will seek to know more about the health of their inhabitants.

A law should not be made about the conditions and health of people living in houses situated above underground streams of water.

It may happen that the shape of the house annihilates any  $V_E$ , that the orientation of the current in a neighborhood surrounding the house means that there is no  $V_E$ , that the composition of the basement is the adequate balancer.

As we have already pointed out, beware of hasty generalizations.

The same is true for high voltage lines. The high voltage line sends  $V$

E-

The range of this  $V_E$  depends on the orientation of the line, the neighborhood etc...

In the worst cases, a 100,000 volt line sends a  $V_E$  about 80 meters away.

|               |                   |
|---------------|-------------------|
| 200,000 volts | 150 to 160 meters |
| 400,000 volts | 300, 400 meters   |
| 800,000 volts | 600 meters        |

- 1) The search for water, still very popular, has been supplanted, given the number of followers, by the manics on health issues.

After 300 hours of training - it takes about 300 hours to be sure of your answer - you can be quite sure of yourself.

The interest of manics in health issues no longer needs to be demonstrated: at the family stage, at the agricultural stage, at the veterinary stage.

We gain autonomy and also an economy that are not negligible.

It should not be inferred that conventional knowledge in human and veterinary medicine is to be rejected. They are perhaps less necessary because only a few diagnoses of symptoms and diseases will be made, but above all therapeutic diagnoses.

That the sick person is sick is very often known. You have to work with

homeopathy, acupuncture and in this case the mancies allow to direct on points which are not the points usually listed.

About people who claim not to have results with homeopathy, they can either refuse homeopathy because for them it is quackery, so the homeopathic products they take are annihilated in their body by their refusal of this way of treatment, either being too intoxicated by allopathy and its remedies, or we come across people who smoke a lot or use hair dyes. Chemical means of contraception can also disrupt homeopathy. Similarly coffee, tea, mint are sometimes contraindicated.

It can therefore be used in the right dilutions of homeopathy. Schussler salts and trace elements - in marketed form: Oligosol - will also be used.

We thus have more than 100 remedies to which we will add some specific homeopathic remedies and some complexes from the Lhening laboratories.

We can help ourselves with publications such as homeopathic dictionaries: that of Pommier for example.

It is necessary to start from the idea that it is necessary to find the remedy which the patient needs - thus with the pendulum one will seek which salt of Schuesler it is advisable to administer or which Poconéol will be specific -.

Schussler's biochemical salts are 12 in number. They come from the trituration of minerals that make up the living organism; trituration is at 6 CH. Among them, three are triturated at 12 CH.

Oligosols are simple or complex trace elements. They are about 15 in number. There are also sulfur and silver Granions.

Poconéols, Shuessler salts exist in the form of small tubes. These will serve as controls.

<sup>2</sup> Poconéol: homeopathic complexes developed by Father Bu's team, these complexes took the name of Poconé, city of Mato-grosso. They are at 5 CH; low dilution ensures safe handling.  
This therapy was developed by missionaries who were not doctors.

Suppose we have a collection of witnesses, we proceed as follows:

- we throw the pendulum in oscillation and we place it above witness n° 1 knowing that we are intervening for such a person
- Two cases:
  - Oscillation holds so it's not for the person
  - We pass to the gyration: it is for the person.

Whatever the case, we go to witness number 2 and we do the same thing.

- Let's make a bunch of valid witness for the person, for example the N° n, p, q.
- We then look at whether 2 to 2 is still valid, if the set of three is still valid.

Indeed in some cases such assemblies may not be valid for the person.

- It is then necessary to see at what times the witnesses who have been retained must intervene.
- Moreover, as the days, weeks, months go by, it will be necessary to retest. Stored cookies may no longer be valid.

Tip: The drainers, for example Poconiol No. 1 and 7, must be given great importance.

Drainers are ignored by allopathy. A poisoned organism must first be cleaned of flocs and toxins.

To the drainers one will add, possibly, a remedy against the constipation.

- Chlorumagen
- Rex Pills
- Sulfur flower powder in honey. The honey must be of good quality. Avoid touching the honey with a metallic instrument.

It is always necessary to fight against constipation whether it is temporary or permanent.

Finally, always follow the evolution with the pendulum - or the rod -.

Young Arkalians,

Your first trimester is over.

You have certainly done well!

The second trimester is coming soon.

*Always be the Paladins of the dawn that is beginning to dawn.*

## CHAPTER 6

### The Vital Field

#### */ Introduction*

Jean de la Foÿe tried to characterize living systems. For this he set up what he named: Champ Vital.

We will present it in what follows.

#### *He The Vital Field*

It was therefore designed and set up by La Foÿe.

The vital field has 4 components which are detected for each from one of these forms.

The first of these forms is called the “Knot of Life”.

Components without the vertical bars are called M-type components.

Components with vertical bars are called E-type components.

The vital field is not quite complete in its description. It's necessary :

- place the 4 components along two perpendicular line segments.

N.F.

SF

- vertically to the intersection of the 2 line segments, a letter is detected

Hebrew: w 1 (schin)

It must be pointed above on the middle branch - which is not found in Hebrew where the point is either on the right branch or on the left branch -.

Thus on a living being, one must detect this vital field.

The node of Life is therefore composed of 2 circles of equal radii, tangent on the outside and at the point of tangency as the center, one draws with a compass 2 arcs of a circle of the same radius as that of the two others.

<sup>1</sup> The 2 perpendicular line segments as well as the representations of the 4 components of the vital field are not enough to set up the schin pointed in the middle

Remarks :

- the node of life is detected in the living human being at the level of the left temple and the navel.
- if it is dead, it is detected at the level of the mouth.
- if you put a coin in the dead man's mouth—a custom of ancient peoples—you no longer detect anything.
- if we do the same experiment on a skeleton, we detect nothing, neither on the left temple, nor on the location of the mouth.

On the other hand, if we intervene from a photo of the living person but who died a long time ago and for whom, after death, a coin was put in his mouth, then we do not detect anything on the photo at the level of the mouth.

The photo gives an indication that we wouldn't have from the skeleton.

- On people in prayer, in deep ecstasy, one detects the knot of life all over the face.
- On deceased people, having worked a lot in non-orthodox fields, it happens that we detect this node of life, even from a photo, on part of the head.
- On animals like the cat, the dog, it is detected at the level of the muzzle and the navel.

But it happens that for these same animals it is detected at the level of the left temple. They then have close contact with a human being. It's not a transfer.

It must be understood that the usual classification in the scale of values, constructed in such a way that the human being places himself in a good position, is not at all valid in the field that we are dealing with here. It is necessary to see much more, if we only consider the animal scale, paths without a possible scale of comparison, but with at times, for certain individuals, possibilities of understanding — this is not imitation —.

Those who are very interested in and love animals alike understand very well what we are presenting. Of course it is not about those animals — especially dogs — which are dominated by their master and subjected to stupid obedience to a few commandments.

These animals there are sacrificed and are a imitation of those of which we spoke above.

- About cattle, sheep, the node of life is detected at the nostrils and at the navel. The same for the horse.
- When the animals are dead, in general, the life node is no longer detected.
- For animals like the elephant, the node of life is detected at the level of the end of the trunk, at the left temple, at the navel.

It was the same for animals now extinct like the mammoth, the mastodon.

- Regarding human beings, the wearing of certain caps, kepis, brings the knot of life to the middle of the forehead. Similarly, the red dot worn by women in India places it in the middle of the forehead.

More generally, it is possible to find multiple shapes that move it to multiple places.

The fact, for a man, to place it in the middle of the forehead favors his ascendancy over other human beings.

This was not calculated, or perhaps the reason was transmitted and then at some point was lost, but the habit of wearing such a type of headdress remained, or even the human being, of instinctively puts in place what corresponds to deep intentions. The 3 hypotheses exist simultaneously.

- The vital field on a human being, if it is detected on a witness of the person: photo ID, lock of hair, etc... is fixed even if the person moves when the test is done; it may be millions of kilometers away, this does not interfere with the test.

If the person is in good health, we find:

SF

but it can happen that this vital field has its components which rotate, the figure around the center rotates by a certain positive or negative angle  $\alpha$ .

Components can interchange, either the usually horizontal ones interchange with each other, or the usually vertical ones interchange with each other.

When the two axes rotate through an angle  $\alpha$  clockwise,  $\alpha > 70^\circ$ , one must carefully monitor whether this rotation continues over the months. There is a weakening of the subject with which this vital field is associated.

In the case of cancer patients, the rotation continues to increase even more in the negative direction, but a vital field which, for example, has rotated by  $-170^\circ$  does not necessarily correspond to cancer. Nevertheless, negative large angle rotations or permutations of the horizontal components should raise the possibility of cancer.

The permutations of the vertical components correspond to quite another thing. They were detected for the first time by J. Ravatin on a plant associated with a form. They

correspond to the index of another form of life that the human species does not seem to know at our time and that this plant had taken for a short time.

The vital field, when an individual turns on itself also begins to turn with a delay and in the direction of rotation of the pivot.

A dancer turning rapidly on one foot catches up with her vital field.

We recall that if we test the dancer from a witness of her, we will not find the vital field in rotation simply, it will be that associated with the human form that is the dancer.

Note :

We insist a lot on the precautions to be taken before any test:

- the precision of the question,
- knowledge of representation.

The vital field for a human being presents its components NF, SF according to the direction of his gaze.

- If he looks in front of him, as soon as his head turns, the vital field follows the movement always with a slight delay and always quite slowly.
- If the person tilts the head, or lies down, the vital field remains in a horizontal plane.

Nevertheless, certain directions of his gaze without head movement can modify the position of the vital field.

- Realization to test the vital field:

We stick on a wooden board a sheet of white paper on which we have drawn a graduated circle and imposed the NF..

Note :

Les formes  should not be shown on the drawing as they would impose always the vital field following the correct position.

You need to be able to check whether it has rotated or deformed. On the other hand, we must not forget to impose the NF..

We place the witness in the center: leaf, lock of hair, etc...

One must detect, if the living witness is in good health, the schin - pointed in the middle - at center, above the witness.

Note :

The planchette does not have to be drilled in its center.

The diameter of the circle may be around 30 cm.

<sup>2</sup> This letter does not exist in Hebrew dotted in the middle; it is pointed either to the right or to the left; nevertheless, it is necessary to point it in the middle to have an answer by mancie; Jean de la Foÿe had found this aut - aut is the Hebrew number for letter, and it seems that it is preferable to use this term because one realizes that an aut is much more than a letter in the sense we understand it in the usual C. de C.

The detection of the vital field is quite delicate. It must be approached calmly and always without preconceived ideas.

Exercise :

- 1) The vital field will be detected on the “trunk of the tree”;
- 2) Consequently, it will be detected on the candle lit with artifice, on the tank where the acid + base reactions take place and there without artifice. It is advisable to redo these

Corrigé :

Note :

There is no vital field associated with a menhir.

Menhirs, dolmens and sites like Stonehenge and many others in the world cannot be approached with impunity without a deep intuition of the other C. de C. where other concepts, absolutely foreign to usual thought, must intervene.

We recently found that the menhirs are linked - or thanks to the menhirs one is linked - to something resembling a field. This can only be detected when one is aware of this “almost field”.

The Ancients used concepts that are not in the rational C. of C., so a machine cannot give an answer about these concepts. It always uses a representation and none of these concepts fit into the usual representations.

It is not enough to say “I work on forms, therefore everything associated with forms is accessible to me”.

We discovered properties of fairly banal shapes as our research progressed and when new concepts were found by us, the shapes were revealed little by little.

The concepts were developed from the necessity and the necessity is done partly from the work on the forms.

In reality, the 2 processes are carried out simultaneously; necessity is fundamental between the two; but it is a special process of the mind and if it is not used, nothing that comes out of these fundamental and profound discoveries is realized.

For example, on each page of this course is presented in the background a form called IDALAB. Idalab has amazing properties.

It emits, worn for example as a pendant on the skin, effects which will not be presented in this course of the 1<sup>st</sup> year, said at very high levels and listed as VC, FV and still what we call Ifs: LD, LA, LC, LB, then the Avcecum and finally a field that we call the ZD (Dynamic) field.

People, supposedly very competent in the field of forms, being in Switzerland claimed that this form Idalab was banal, even harmful in certain cases.

It is necessary to know, and we have just developed that they could not approach this form since their knowledge created in it a state of insurance and sufficiency in the approach of any form. They have not understood, felt what a form is, the concept of form escapes them.

In the case of AIDS, we find that the components of the vital field are no longer perpendicular.

- Very tired, depressed people have a weak vital field - that is to say that the components are more difficult to detect -,
- For people wearing a motorcycle helmet - which encloses the head - the vital field can no longer be detected, even with artifice.
- The life node on the left temple is weaker.

Exercise :

Make a wooden plank, parallelepiped of length 2,

width 3<sup>3</sup>

thickness of your choice.

<sup>3</sup> The proportions must be respected.

1) Check that we detect:

and this on the axis NF, SF

2) Check the polarities

3) Check that a pebble placed in the SF emits the components of the vital field.

Exercise :

We start with a good piece of parallelepipedal wood:

Its axis is placed along N.-F., SF.

We put a freshly picked leaf on this plank following the drawing, the petiole towards the SF

Check :

- 1) that the life node is detected at the SF.
- 2) the leaf, alone, thus directed, emits the node of life by its petiole.

Exercise :

We set up a battery of full half-spheres, for example 3, whose horizontal axis  
auN.F., SF.

VS

4

We send the node of life - for example by the assembly of the previous exercise

- 1) Check that it is detected along AB (see figure above).
- 2) Check that it is detected at SF, ie at CD, the life node and V'M- Note: The best V'M is ineffective if it is not accompanied by the life node.

Exercise : We reproduce the shape of a rosebush thorn and place it like this:

Show that we detect the knot at the SF.

Exercise : We associate 3 solid wooden spheres according to the assembly below.

We send the life node and an eif according to what is indicated on the diagram.

Show that the life node is detected at the SF.

One night Chuang-Tseu <sup>4</sup> dreams that he is a butterfly.

When he wakes up he asks himself:

“Who am I really:

a butterfly which dreams that it is Tchuang-Tseu

Where

Tchuang-Tseu who dreams that he is a butterfly? »

<sup>4</sup> Tchuang-Tseu or Tchouang-Tseu (IV<sup>th</sup> or beginning of the m<sup>th</sup> century BC).

Chinese Taoist philosopher, successor of Lao Tseu and remarkable writer of the Tcheou period.

His work, the "Tchouang-Tseu", develops with dazzling verve the themes of Taoism - this being the direct, intuitive understanding of life and the global vision of the world; in the same way it goes in the direction of the development of the natural spontaneity of the spirit, (the human self no longer intervenes) - in unique anecdotes, often ridiculing Confucianism then considered artificial and heavy, or deep jokes which might seem, to unprejudiced minds, sparkling paradoxes.

Note : we will see in other chapters the emitting discs and squares and then the life node comes out with the eif.

### */// Consequences*

- It should not be deduced from this that the living can be described by a vital field. We have also seen that we could impose a vital field on a stone.
- Can we say that every living system has a vital field?
  - We have seen that certain sick human beings have an undetectable vital field even by artifice.
  - That an AIDS patient has a completely disturbed vital field.
  - But also we realized by studying the living beings that are in the Val sans Retour<sup>5</sup> in the forest of Brocéliande in Brittany - fish, frogs, birds, trees, multiple grasses - that they did not have a vital field and this whatever the tricks. It seems that an operation was set up about 7000 to 8000 years ago on this region.

As soon as these animals - and this is the case with birds - leave this region - the Valley of No Return - they find their vital field.

It should not be inferred that the Fontaine de Barenton, also in the Forest of Brocéliande, has the same properties. It stabilizes, imposes even more the vital field.

Exercise : We take three stones of approximate shapes — which we place on the ground in the following way:

Suppose we have 2 underground water currents at different depths, one oriented North-South, the other East-West.

<sup>5</sup> Results obtained during the studies carried out within the framework of the Congress from June 29 to July 7, 1996 in Camac

— — — — —

#### IV Realization of the pendulums of the vital field

We start with a hard plastic cylinder, like those for the polarities.

We glue rectangles of paper on which have been drawn the 4 shapes **CDIICDIIQIB**

and also a pendulum with string which crosses on which ~~glue~~ **127**.

#### Conclusion :

The living has not been characterized by the vital field. We found another form associated with life. It is the fundamental form of the Living.

We will present it in the next chapter.

## v *Brain Walk*

Man has always sought to use natural forms for his benefit and for his pleasure. To achieve this, he chose "de facto" the existence of a natural order of things of which he was a part and to which he had to submit. This natural order to which it belongs depends on the representation chosen. It is necessary to soak up the fact that the representations of the rational world in which we are at this moment - Usual field of coherence <sup>6</sup> - are not those of the Ancients who were in the Other Field of Coherence (C. de C.) .

This intelligent, pre-established order - if we consider the usual C. de C., otherwise it is a cerebral construction if we consider the other C. de C. -, intelligible, and hierarchical is the necessary support for experimental realizations. If we want to continue our study, we will need, as our ancestors undoubtedly did, to soak up this order and think about this order with structures that adapt to those of this order - it is an approach which is not in the usual thought - so as to live in harmony with nature and to preserve our physical as well as moral health.

<sup>eifs</sup> and everything associated with them and which we will study even more in the course of the 2nd year, we will try to find this order.

For this, as Louis Charpentier says, it is necessary to go back to the "Essence of Things".

## Chapter VII

### The Fundamental Form of Life

#### */. The Fundamental Form of Life (FFV)*

The vital field of Jean de la Foÿe does not characterize the living; we saw that we could make it appear on a stone.

We are in a field where characterizations can be transported from one form to another.

But nevertheless, let's try to characterize before transporting.

A new form is presented which will intervene in all the living: it is about the Fundamental Form of the Living.

It is not flat; it is composed of 3 segments OA, OB, OC such that OA is vertical, OB=OC and  $\angle BOC = 120^\circ$ .

Let OH be the height of the isosceles triangle BOC and  $\alpha = (\angle OH, OA)$ ;  $\alpha$  is equal either to  $33^\circ$  or to  $43^\circ$  but of these two values it is the first which seems the best, so we will retain  $33^\circ$ .

If we take OA=OB=1, we find for OA the value  $ip$  where  $ip$  is the Radiant number discovered by Gérard Cordonnier in 1924 and which we will study in a special chapter reserved for it,  $ip = 1.324...$

#### Notes :

This form can be detected on any living being, even on bacteria.

It does not depend on the position of the living being in space, for example a human being may be standing, lying down, head down, it is detected in the same way.

It is not in our usual space; it presents itself, for this, as the vital field. Can we say why it is delocalized? Yes ! We imagine it as being in space, but it is not there.

### *IL Form associated with FFV*

FFV has a very interesting property that has multiple applications. At the vertical of O, at the level of BC, a completely delocalized form is detected.

It is called rhythm form associated with FFV. We find a fixed form that realizes this rhythm. In the expression of a rhythm, there is no origin so the shape can be built from a circle.

It is a flat, closed curve. The circle serving as the base is retained.

The rhythm can be expressed as  $\{(1, 2, 3), (4, 5, 6)\}$  that is to say twice a group of 3 and then we repeat identically. The circle will thus have 6 marked points.

Let's draw a circle divided into 6 equal parts, of which 6 points are listed from 6 as in the figure:

The segments will be designated by doublets of 2 digits, the first designating the origin, the second the end.

$\{1, 2, 3, 4, 5, 6\}$  is an irregular star hexagon.

The figure should be understood as follows:

$\{2, 1\}$  turns into  $\{2, 3\}$  which we will write  
Then  $\{3, 2\}$  turns into  $\{3, 4\}$ ,  
then

$\{2, 1\} \wedge \{2, 3\}$ .  
 $\{3, 2\} \longrightarrow \{3,$   
 $4\}$   
 $\{4, 3\} \wedge \{4, 5\}$   
 $\{5, 4\} \wedge \{5, 6\}$   
 $\{6, 5\} \longrightarrow \{6,$

and it goes back to the beginning.

The hexagon with the circle emit what we call the first Taofel field which is an eif which belongs to the class of eifs known as Taofel fields, but this will not be studied in this course.

### Exercise :

We can make an assembly with transistor and LEDs that light up according to the rhythm {2, 1} -> {2, 3} That is, {2, 1} lights up first and then after {2, 3}. Of

{3, 2} -> {3, 4}      {2, 3} or {3, 2} we then move on to {3, 4} etc... And so on.

{4, 3} -> {4, 5}      The frequency should be such that the eye no longer sees the changes. The frequency is determined with a pendulum. This varies

{5, 4} -> {5, 6}      according to the assemblies. Eifs come out and leave at about twenty

{6, 5} ^ {6, 1}      meters but can carry further if the size of the assembly is more

{1, 6} -> {1, 2}      large. We obtain eifs which are very good for the health of

etc...      beings, these being placed at approximately 1 m.50 to 2 meters from the device.

Eifs are not in the EFF domain; we find the fields of Taofel and two other eifs which are Creative Verb and Famous Green (this one has nothing to do with the V + or the V, V'E, V'M, VE, V'M).

### Note :

Let us consider these beings which were sometimes observed, often for a very short time, by travelers on land or at sea; these are the Loch Ness monster and other lake monsters, sea serpents, beings such as the Yeti of the Himalayas, the Sasquatch of the west coast of Canada, more precisely in the mountainous region of British Columbia, further north, just across the border from the United States, they have absolutely no FFV

Another form is associated with them. In perspective it looks like this: OA is horizontal.

$\angle A (OB, OC) = 120^\circ$ . The angle of the BOC plane with OA

extended is another  $33^\circ$ . Moreover there is FG which is perpendicular to OA and vertical and which is placed in the plane of symmetry of OB compared to OC.

We have  $OB=OC$  but OA is no longer equal to ip. Its length may vary depending on the location. With UFOs, sometimes such forms are associated. It is associated with a form-rhythm which is not detectable in the extension of OA and is totally different from that found for living systems.

In these beings - aping of the living - we do not detect a vital field, or at least it is not like the one we described in the previous chapter.

Exercise : we will practice detecting the FFV associated with human beings, animals: cats, dogs, plants.

Note : Sometimes humans do not have FFV. It's quite rare. However, if this happens, the person's state of health must be seen in detail. There are anomalies.

“And the moment he knew it, he ceased to know it”

Jack London <sup>1</sup> II

<sup>1</sup> This thought is the last of the work of J. London, “Martin Eden”; it expresses the death of Martin Eden who sinks into the ocean.

Jack London: born in San Francisco on January 12, 1876. His story is a novel worthy of those he wrote; he was, one might say, his own model.

He was the natural son of a traveling astrologer of Irish descent. His mother, shortly after his birth, married John London, who gave him his name.

Miserable childhood, on a ranch where he watched the bees, then in Oakland, where his parents ran a humble drugstore. He had many jobs, was sometimes arrested for vagrancy, but had a taste for books early on.

At fifteen he became a sailor and sailed the seas.

At nineteen, he entered the Oakland School, then the University of California.

In 1896 he left for the Klondyke.

Called back to Oakland by the death of his stepfather, he published short stories in various magazines and began to live by his pen; but he quickly squandered the often considerable sums he earned.

In 1903, his admirable “Appeal of the Forest” was released.

From the Hawaiian Islands where he went with his second wife, he brought back “Martin Eden”.

He committed suicide on his luxurious ranch in California on November 22, 1916.

It is also interesting to talk about him being linked to Jules Verne by a mysterious group of 7 people including Jules Verne, Jack London, Amundsen, Edison... and an even more mysterious Dad who seems to have wanted to make known to humanity a path of science and wisdom. But it seems she refused. We talk about it in Vladimir Roznilk's book “The Emergence of Enel or the Immurgence of Landmarks, Introduction to the Study of Forms and Coherence Fields” (Volume III page 705).

About Jules Verne we learn that he was attached to a form called Pentacle of Jules Veme or Medal of Jules Veme. This form has multiple properties.

## Chapter VIII

### States and levels of Equivalence

#### *I. Introduction*

To implement the concepts of state and level of equivalence, we need letters from sacred "alphabets" such as Hebrew. We will only stick to this one.

But one could consider Sanskrit, characters from the Easter Island tablets or the so-called "Enochian" characters of John Dee, Queen Elizabeth I's <sup>astrologer</sup>. It had been given to him through the use of a certain mancia, characters he used effectively in his experiments. He had achieved great operability.

#### *II. Hebrew letters*

Thereafter we will not use the name letter for these forms but the Hebrew name: aut and in the plural autioth because they contain much more information by their form than the letters of our modern languages.

There is an exception, it is the Basque which uses the Latin letters but the words emit all that one can detect with the Hebrew, on the other hand the letters do not emit very interesting things. Basque is one of the most difficult languages to learn - 12 declensions per word - in the world but incredibly rich. Basque folklore is also very interesting, for this you have to delve into the works of Father José Miguel de Barandiaran, of whom unfortunately only one work has been translated into French; the rest is written in Basque. Only one translation of his immense work has been made into Spanish <sup>2 3</sup>.

The Hebrew must be written in so-called "square" - biblical - Hebrew, otherwise nothing can be detected.

<sup>2</sup> José Miguel de Barandiaran, Basque Mythology, Edit. Annals of the Pyrenees, ESPER Association, Toulouse, (1989)

<sup>3</sup> See the book by Jacques Ravatin and also the soon-to-be-published book by Jacques Ravatin and Anne Marie Branca "Theory of Forms and Fields of Coherence" (to be published).

The autioth are, for each, developable into several autioth. This is very important because it enriches what is linked to an aut and to a word when we do this development for each aut of the word.

Moreover, each aut corresponds to a number. Note immediately that there is no link between the number associated with Faut and the number. For example, to Aleph it corresponds to 1, to Beith it corresponds to 2 and to Tâv it corresponds to 400.

On the attached table are 2 correspondences:

- The one indicated under each aut which is the correspondence of kabbalists and rabbis.

1.2.. .., 9  
10, 20,..., 90  
100.. .. 400, 500,...900

There are 22 authioth, but when some are at the end of a word - in final - for 5 of them correspond the numbers of 500, 600, 700, 800, 900.

Note that there is also a correspondence between the letters of the Greek alphabet and numbers.

In this alphabet, letters were removed by the high priests such as the koppa (which is not to be confused with the kappa). Recent work carried out by researchers from the EUREK'ALL Company, the DECALUM association and the ARK'ALL group have shown that the koppa has strange properties and makes it possible to go very far. For this we must work on what we have discovered and called the P-Champs - for almost-field -.

By test, there is no link between an aut and its associated number. The number should not then be understood as 10, 20, 200, etc... but as the succession of the digits 1 and 0; 2 and 0; 2, 0 and 0 but that is not enough: you have to build a sequence for each triplet of numbers.

- On the table of autioth at the top of each letter, on the right is shown the order in which they are distributed. It is this correspondence which was kept by G. Bardet who violently criticized the rabbinic numbering.

From the correspondence of G. Bardet, Jean de la Foÿe drew what he called "the canons" which are cylindrical sticks on which are worn grooves corresponding to the autioth but these autioth are represented by Bardet's numbering.

One could also, in the numbering of Bardet, use sequences starting either from 2 numbers for example and by placing a zero on the left or on the right of the number or numbers.

Bardet established a writing of the autioth which is practical when one has, as in the case of computer use, difficulties in using Hebrew characters directly.

### Notes :

- Thus the autioth go from hA to Th.
- In Hebrew the language must be felt, not as a grammatical understanding, but given as a whole.
- The first 9 autioth are said to be archetypal.
- For Carlo Suares <sup>4</sup> :
  - the autioth related to the units intervene in the field of the archetypes.
  - the autioth linked to the tens intervene in the realm of the incarnate.
  - the autioth related to the hundreds intervene in the cosmic domain.

We will not make such a distinction and will not use this breakdown.

- We say Hebrew or Esdraic writing.
- Hebrew is written from right to left.

When we take Bardet's handwriting, we will do so from left to right.

But it must be said that the writings of Bardet autioth or words emit nothing.

When you want to detect eifs, test states, make pendulums with aut or word, you have to use square Hebrew.

The ancient languages, often sacred, correspond to a thought that is no longer ours. But the forms of the signs, of the autioth in this case, carry with them the reason for their creation, the reason for their form, the information of meanings. You have to wait and not impose once again the usual thought.

- 150 years ago, Champollion published his famous memoir on “Phonetic Hieroglyphs”.

He said: “Egyptian hieroglyphs neglect vowels, they only represent consonants”.

It was a successful but mistaken working hypothesis. It will lead to this false double affirmation: "The Hebrew letters and the Arabic letters are only consonants".

Sir Alan Gardiner, in his monumental “Egyptian Grammar” observes that certain Egyptian signs do not only represent consonants.

<sup>4</sup> Carlo Suarez: “The Kabbalah of Kabbalahs”

There is a full writing, that is to say where the vowels are written. In the 26th <sup>dynasty</sup>, vowels were written and this in certain regions.

Similarly Régis Blachère in his “Elements of Classical Arabic” specifies that the signs Waw and Ya have consonantal value when they are accompanied by another vowel, but are long vowels when they are not articulated with the following vowel.

In reality, all pronunciation requires vowels; in a language like Czech, we use vowels even if they are not written.

One may wonder whether intelligible sounds in languages are necessarily heard if they do not contain vowels. And there we feel the concept of vowel emerge. So we cannot say: there are vowels or not, but we must say, there is emergence. This is the way to talk about vowels.

- Note that if Champollion deciphered the hieroglyphs, he only gave an interpretation. Another was found by a French researcher Louis Boutard. And in this other interpretation there is this game of the mind that we find in particular in Kabbalah and which was appropriate among the Ancients.

Champollion has, through usual, analytical thought, rethought ancient languages which were only slightly analytical despite the discovery of grammars for them.

It may be secondary to a system of expression and understanding.

- Let's see the h A: it is existence that corresponds to existence without landmarks and existence of concepts - Concepts, for some, are before benchmarks. They can announce them.  
The hA is linked for example to the concepts of global, local, field of coherence, radius of coherence, swarm of coherence, island of incoherence, etc...

We say that the h A is the 1; it is the 1 next to the 1. It accepts to be in tension <sup>5</sup> with the 1 to become impregnated with the 1.

The B <sup>6</sup>: for the same reason as the hA, it is the 2: the 2 without which nothing would be say the right home, the true one, the one you need.

This word remains corresponds to a delocalized concept. It's a bit like the concept of home but still different.

<sup>5</sup> See book by J. Ravatin and Anne-Marie Branca, Theory of Forms and Fields of Coherence (to be published)

<sup>6</sup> See correspondence table between Autioth and Latin script

For Carlo Suarès, the B is the archetype of all containers, "homes".

This is the exact concept.

In the B, there is h A.

But the hA contains all the autioth.

- The autioth are for each developable. This is important because thanks to these development of each aut of a word, one can pass to other words or even elaborate new words. The latter, one can verify by manie, in certain cases will not be to be rejected.

We will give this development for each aut in a vertical arrangement of the autioth.

|    |    |   |    |    |   |   |    |    |
|----|----|---|----|----|---|---|----|----|
| Ha | B  | G | D  | H  | W | Z | cH | T  |
| L  | Y  | Y | L  | Ha | W | Y | Y  | Y  |
| Ph | Th | M | Th |    |   | N | Th | Th |
|    |    | L |    |    |   |   |    |    |

|   |    |   |   |   |   |     |    |    |
|---|----|---|---|---|---|-----|----|----|
| Y | K  | L | M | N | S | chA | Ph | Ts |
| W | Ph | M | M | W | M | Y   | HA | D  |
| D |    | D |   | N | K | N   |    | Y  |

|    |    |    |    |
|----|----|----|----|
| Q  | R  | Sh | Th |
| W  | Y  | Y  | W  |
| Ph | Sh | N  |    |

We therefore write a word and under each aut its development. By reading horizontally, other words or even sequences of autioth can be formed which, as we have just pointed out, do not apparently no sense.

### *///. Hebrew words*

When working on forms and when using Hebrew, you have to walk around the word, around all the autioth of the word. We can only stick to one meaning of the word; in Hebrew if one attaches oneself to a direction, where the other sounds are more less present. This is what is called the “Nebular” of the word <sup>7 8</sup>.

Let's see for example BR hK Sh Y Th, the first word of the Torah.

<sup>7</sup> Name of the in-depth developments on this Nebular term, we will refer to the work of Jacques Ravatin and Anne-Marie Branca already quoted.

<sup>8</sup> Berechit is the pronunciation

The translation from Hebrew into Greek, from Greek into Latin and from Latin into French, or from Greek into French leads to "In the beginning", which in current thought corresponds to nothing compared to the original meanings - because the meanings are multiple, not in the sense of several but in the sense of a cloud containing potential information that can be modified according to the shape of the cloud, the pressures inside or outside the cloud, etc... The word is there to remind us that it is ready to everything as long as you know how to use it.

Example: BR hA Sh.Y Th

Meanings: To invent look with intention,  
lie throw,  
assume to hide, to steer, to travel, to move, to  
lurk, to keep hidden

So with Berechit we feel that what is going to follow is already at stake - if we consider the continuation which constitutes the verse because it is said that the continuation is in this word - , that there will be invention, creation but that it is as if hidden, one supposes, there is the intention, one must look, move, direct oneself, be careful, observe. We thus arrive at the diagram presented in Volume IV (Page 1101) of "The emergence of Enel..."<sup>9 10</sup> where we use 3 signs 'N-, \_S\_

... looks like enough

h guess

to be (in the sense of existing)

and is read when written I HAS A where A. is a presence, a thing, finally what is  
HAS A

observed, what we are talking about. We state:

A sufficiently resembles what A supposes to be  
so that I suppose  
What A is what A sufficiently resembles

<sup>9</sup> The Pentateuch in Greek -the first book of the Bible which includes 5-

<sup>10</sup> Vladimir ROSGNILK, The Emergence of Enel or the Immergence of Landmarks. Introduction to the Study of Forms and Fields of Coherence, Editions ARK'ALL Volumes I and II (1985), Volume III (1988), Volume IV (1990), Paris.

Jacques RAVATIN, Coherence Field Theory, Edit. C. Lacours, Nimes (1992).

Jacques RAVATIN and Anne Marie BRANCA, Theory of Forms and Fields of Coherence (to be published)

In Berechit there is that. The Berechit expresses the value of the human formulation <sup>11</sup> and

To the attitude of man in front of this formulation. Also in the scheme I it

AA

<sup>12</sup> is suggested that to create one needs the intention of the intention. This is the two - the 1 not being accessible to man but found in the accessible form which is the divine ternary of Enel, Prince Skariatine.

But we can also work on Berechit in the following way:

|       |        |         |            |
|-------|--------|---------|------------|
|       | BR     | hA-Sh   | Y-Th       |
| Where | B      | R-hA-Sh | Y-Th       |
| Where | B      | RY-Th   | hA-Sh etc. |
|       | etc... |         |            |

Then we use the development of each aut:

|    |    |    |    |   |    |
|----|----|----|----|---|----|
| B  | R  | hA | Sh | Y | Th |
| Y  | Y  | L  | Y  | W | W  |
| Th | Sh | Ph | N  | D |    |

And work with the 2nd and 3rd rows as we did for the first row.

Let's see an expression from the beginning of Genesis:

Earth is Tohu-Bohu.

Tohu-Bohu has a very particular meaning taken in French, ie confusion, disorder, often noisy: "it's a real tohu-bohu".

Th HWWBHW these 2 words mean the same thing

that is: Chaos, emptiness, void nothingness, desert, loneliness, confusion, disorder, chaotic condition, futility.

The same meaning entails a vision of 2 as expressed by the Templars in their seal: 2 riders on the same horse <sup>11 12 13</sup>.

Complementary to this writing of Tohu-bohu is the expression: signifies

Q u i

chaos, shapeless mass, nothingness, solid, desert, emptiness, vanity, vain thing, deserted place,

<sup>11</sup> We will say for observer man or more precisely Obs what is more general than the observer - see the works of V. Rosgnilk, AM Branca and J. Ravatin.

<sup>12</sup> See the work by Jacques RAVATIN and Anne-Marie BRANCA already cited.

<sup>13</sup> This is called a T system. See "Theory of Forms and Coherence Fields" by J. Ravatin and AM BRANCA (forthcoming).

Thus we realize that the sacred languages, such as Hebrew, Sanskrit and others which have disappeared, like undoubtedly the few which have been found on the 28 tablets still existing on Easter Island, were all completely different from what our modern languages have become, at least what we think of them.

We can then suppose - but this is only a supposition that some researchers have considered - that at the beginning of humanity there was only one language. If it still existed, is it necessary to have a representation that leads to the establishment of an origin of humanity; in the works of Vladimir Rosnilk, Jacques Ravatin and Anne-Marie Branca, there can be different origins to humanity, this depends on the Ray of Coherence chosen and enters into the Model called Coherence Field Theory - one can therefore think that we would be faced with a language that would have been evocations in the process of evolution.

The words are hardly expressed, they are similar, one passes from one to the other by a drift <sup>14</sup>, as one would pass from a blue to a yellow of the visible electromagnetic spectrum by using all the intermediate wavelengths. It is a poem where the evocation is launched towards the one who waits and when he receives it it transforms him into a radiant source.

If with Th HW Sh YW we want to use the numbers

we start from 400 5 6 300 10 6

Which we write as follows:

4 0 0

0 0 5 And we read the sequences constructed as we established previously.

0 0 6 We will not go any further down this very rich path.

0 0 3 extraordinary but which quickly takes us out of the scope of this course.

0 1 0

Note the expression: La Terre Y <sup>hA</sup> T®; the name Moses p; A Sh H Female

Let's go back to the expanded hA:

I h A We can have fun doing the total: say 111 and add up the 3

3Q L number 1 which gives 3. It should not be deduced that 3 is the ternary

on divine n1 and that the hzA contains this ternary. This then is the esotericism of low class, moreover it is the one found almost everywhere.

II should work like this:

<sup>14</sup> Deviates from the meaning of the works of J. Ravatin and Anne-Parie Branca.

1 ----->00 1 1

30 ----> 0 3 0 J- and construct the appropriate sequences then add them.

80 ----> 0 8 0 J

Advice : For any work involving Hebrew, it is necessary to have at your disposal dictionaries of the type:

Abraham ELMALAH, New Complete Hebrew-French Dictionary, Edit. Yavneh, Tomes I, II, III & IV, Tel Aviv (1974).

And French Hebrew

Menahem BANITT, French-Hebrew Dictionary, Volumes 1, 2, 3, 4, Edit. Masada (Israel)

Example :

Consider the word Sun: Sh Ms h in which we develop each aut.

Sh M Sh

Y Y Y

NMN Arrived at NMN we continue the development

W Y W

N M N And this happens every two lines:

MN -----> manna

NM -----> dormant

This causes the sun to bring manna in a dormant form. It looks like in our time, in the potential state.

And so NMN could be, if we use the language of forms, the equivalent of the form associated with the void.

N -----> fish but it is the expression of the sensation one has when one sees a fish to undulate, to move in the liquid medium.

But it is still: swarming, degenerating.

This means that NMN presents itself as a biological medium between two dynamisms.

And it is enough to unbalance one of the two to pass from a potential state to a kinetic state, one would say more correctly to pass from a dynamism to localized.

50 MQ <sup>1 ser</sup> P <sup>en</sup> t but also omen, spell, oracle, presentiment, divination, presage, enchantment, prognosis, auspice, magic, superstition.

And we will also use a lot K Sh Ph (the dot above for the schin) which means to be <sup>20 300 800</sup>

bewitched, be enchanted.

Note : do not forget the Ph which is in the final therefore not 80 but 800.

Et K Sh Ph YM for magic, sorcery, divination, enchantment, spell, arts 20,300 80 10,600  
chimerical, evocation, magic, incantation.

There is also hAWB.

K Sh W Ph - M Th YM

DRY Sh H

hAL HM Th YM

We will have to use pendulums bearing K Sh Ph <sup>15</sup>.

We will then think of magic, but in a sense where it is a state which is not made for human beings or for which the one who approaches the form or forms is not ready for this exercise. It is possible, moreover, that there exist states which characterize forms for which the human being cannot undertake a study.

There are such forms - which are called "intestable" - which indeed give little or nothing about their properties but nevertheless do not respond to K Sh Ph or to any other state of this kind <sup>16</sup>.

You should know that when we have an answer to K Sh Ph it will be the sense of magic but impregnated by all the senses that we presented above.

They constitute what is called the "Nebular" of the word.

In our modern languages words have nebulae but they do not permeate the word.

But it is not only the form of the autioth which intervenes to use the nebula of the word, it is also necessary the state of mind. We naturally have this state of mind - there are few individuals who are like this - or we can take it little by little by studying the works of Anne-Marie Branca and Jacques Ravatin as well as that of Vladimir ROSGNILK already mentioned. The thought elaborated in these books is called Arkalian thought, from the name of the group ARK'ALL.

Appropriate pendulums :

It is necessary to make pendulums for the words K Sh Ph (magic),

H h AR Ts (Earth),

<sup>15</sup> The Sh must be pointed "in the middle", without this, there is no answer for the search for this state because we will see later, it is a state.

<sup>16</sup> We will see other states of this kind when we approach the study of the states

LN Ph Sh cH YH (the Breath of Life),

RW cH ((the) Spirit),

Y HWH - one of the names of God, we find others in the Thôrâh <sup>17</sup> -,

hA WR ((the) Light),

Y Ts hA WMYM (He will spring water),

R WcH,

Sh T N.

— We realize in a hard plastic material as we did for the pendulums of the 4 components of the vital field and the schin, a cylinder on which we stick the word in square Hebrew.

### Supplements :

Sh TN Schatam, that is to say satan, evil inclination messenger of death. <sup>300 9,700</sup>

H hA R Ts

pronunciation: haretz

Meaning: Earth

LNPhSh cH YH

Pronunciation: The Nephesh Raiah

Meaning: breath of life

R WcH

pronunciation: rouach

Meaning: spirit, but also: air, wind, strong breeze, breath, breath, respiration, aspiration, soul, life, ghost, passion

Then sides, flank, heart, vanity, nothing, frivolity, courage, desire, will, anger, anger, conscience, werewolf, demon, evil spirit, memory, memory, idea, thought, intelligence, conscience.

<sup>17</sup> The Pentateuch, Tomes I, II, III, Lib. Colbo, Paris (1983)

Exercises : We start with a sheet of white paper, we draw any triangle on this sheet.

- 1) Check that in general the pendulum K Sh Ph reacts above the triangle.
- 2) Jean de la Foÿe had noticed that in the case of right triangles of sides 3, 4, 5 the pendulum K Sh Ph did not respond.
- 3) Check that more generally the pendulum K Sh Ph does not respond on any right-angled triangle of sides  $n, p, q$  and where  $n^2 = p^2 + q^2$  and where  $n, p, q$  are integers - This recalls Fermât's theorem- .
- 4) Check that in the same way the pendulum K Sh Ph does not respond on a triangle of angles  $40^\circ, 60^\circ, 80^\circ$  - this one is linked to the Radiant number of Gérard Cordonnier-.

Exercise :

- 1) Check that the tree trunk, because we have its 2 perpendicular axes in pure E and pure M, we detect perpendicular LYL H.

- 2) We start with a parallelepipedal piece of wood as shown below.

We impose a polarization with the grooves and a hole in the center and an antenna with a solenoid +.

- a) Whatever the direction, we detect at the places indicated LY L H.
- b) Same assembly with flower pots.

- 1) Check the polarities.
- 2) Check the dramatic differences in germination at the ends.
- 3) Check that the assembly meets K Sh Ph.
- 4) Check that above the pot on the left in the diagram, we have the right schin, and that above the pot on the right we have the reversed schin.

Conclusion : This is a dangerous assembly because we detect K Sh Ph with Sh on the whole assembly - the assembly must be thought of as a single form and not as an association of forms which would be: the piece of wood, the solenoid, the flower pots.

## */I. Broadcasts from another*

Jean de la Foÿe noticed that the autioth taken separately emitted from one point.

I

Let's see some autioth:

|     |     |   |   |    |   |   |     |         |
|-----|-----|---|---|----|---|---|-----|---------|
| •   | VS  |   |   | /  | E | r | ï'  |         |
| Sh  | Sh  | \ | Y | w  | D | R | Ts  | M final |
| 300 | 300 | H | 5 | 10 | 6 | 4 | 200 | 90      |
|     |     |   |   |    |   |   |     | 600     |

Note: The eifs come out where the arrow indicates

### Notes :

- an aut can emit several eifs at the same point.
- If the autioth are in a word, the emission points are not necessarily the same as on each aut taken separately.
  - When we consider a word, what it emits depends on the representation chosen.
    - or we are looking for a precise meaning to the word.
    - or we consider the word and the nebula attached to it.

## *IL Equivalence levels*

The levels of equivalence appear during the rational representation of the different kingdoms.

We have for example:

- mineral
- vegetal
- animal
- human

Jean de la Foÿe, who had established them, presents them in this way to associate them with the eifs.

- Eifs “in physics” characterized by H hA R Ts
  - pronunciation: haaretz
  - meaning: Earth
- Eifs “in vital” characterized by LN Ph Sh cH YH

<sup>1</sup> Here it is an eif which is from N<sub>E</sub>

a meaning: divine breath

- Eifs “in spiritual” characterized by RW cH
  - pronunciation: Ruah
  - meaning: Spirit

Exercise : Find the emission points of the eifs on each aut.

|                             |                            |                            |                            |                                |                             |                                |                               |                             |

Exercise :

A circle is drawn on a sheet of white paper. In the central part a schin is placed.

We impose the NF

Check that the undifferentiated spectrum is detected around the circumference of the circle.

Answer :

Notes :

If we put the schin upside down what happens? We don't have the same thing because we had to impose the NF.

/Thus the Eifs will be of different types - they will be at different "levels of equivalence" They will have different characters depending on the level of equivalence.

We will also see later the statements on the forms and e in different states.  
important. We will see this in the following presentations.

hich are carried in square Hebrew the words:

Assume the eif at 3 levels of equivalence.

- 1) Check the output equivalence levels as shown in the figure.
- 2) On the path of 1 is placed a living plant or animal witness.
  - a) Check that the LN Ph Sh cH YH part is stopped.
  - b) Check that the part in RW cH continues.
  - c) Verify that RW cH is intercepted by a live or dead human witness.
  - d) The H h AR Ts part always passes.

Notes : In RW cH:

- a) we can have troubles for example saturation of the devices.
- b) if an eif is emitted by a very fine needle, it is, at this level of equivalence, transformed into a brush.
- c) If a  $V^+M$  is in this state of equivalence, we do not detect  $V^+M$  but an unpointed W. In the particular case where the  $V^+M$  is emitted by a needle, we find the  $V^+M$  very close to the axis but it is never very clear.

The RW cH “locks us up” in a domain where we risk no longer being masters of the phenomena or of the detections.

Forms that emit at all 3 levels are mostly depolarized.

They are qualified as “magic” because they make the pendulum K Sh Ph react upright or upside down as well as the pendulum

DRY Sh H h ALHM Th YM

We put the dot in the middle of the schin in order to have an answer.

These three words mean: communicating with the dead, necromancy.

Forms that respond to this are said to be “incomplete”. For Jean de la Foÿe, they would have a void to fill.

If an emitting form such as a "tree trunk" is passed to the equivalence level "RW cH or if it responds to K Sh Ph, then the polarized body rotates 180° which causes the eif Vj to pass to l west and the eif R passes to the east. In this case often the pendulum Sh TN (Shatam) also responds. We cannot guarantee that this is always true because in this area there are very often exceptions. Naturally if the person imposes laws, he finds them. As we have already pointed out, it is richer not to impose anything a priori in its representations.

### *///. The states*

To forms, to eifs, we can make states correspond.

These states are the transposition of the concept of state that we usually find in these forms, eifs. We are talking about the state of a person, state of health, fatigue, the state of a system in rational mechanics.

The states are generally delocalized; and even in everyday life, the state of a person who will say “I feel good” is not measurable. We can not compare it to that of another person who will pronounce the same sentence to speak of himself, of his condition. On the other hand, the same person will be able to talk about the improvement of his condition; this state is little localized by these last two remarks. And yet we talk about it in the usual C. de C.! Effectively in the usual C. de C., as we have already pointed out, concepts related to the global are used. It is necessary to become impregnated well that because of the discipline of spirit necessary to the development of the knowledge of the forms and the expansion and the richness of this knowledge, it is necessary to withdraw from the rational thought a certain number of concepts that seem like anachronisms in the society in which we increasingly need to immerse ourselves, a society where measure becomes necessity. It is an approach that

to move certain sensations and use them as a directional support for the construction of Coherence Fields.

Thus the usual C. of C. becomes its exhalation. He is more and more what we see in him. In this sense he is inhuman.

We saw at the beginning of this chapter for the first time the term transposition to designate the use of a word, in this case that of state, in a context where it did not exist. Rather than creating another word and moreover the process used which is that of transporting a concept from one domain to another domain, an enriching movement, we do "walks" of the concept, but guided walks, not wandering - in the latter case this too is very rich -.

So we are now going to talk about the state; the state of a form, of an eif. In these cases the states will be completely delocalized.

We are going to characterize them by Hebrew words, written in square Hebrew, carried on cylindrical pendulums. But states will be marked otherwise.

Thus we find the state K Sh Ph - to avoid repeating the word state we will write  $| K Sh Ph \rangle$  but beware: the  $| \rangle$  should above all not be worn on the pendulum; inside  $| \rangle$  we put the square Hebrew -.

It is necessary to add  $| KShPh, Sh \rangle$  which specifies the state even better; we will also have

$| K Sh Ph, Sh reversed \rangle$  and again  $| K Sh Ph, Sh reversed, Sh TN \rangle$ .

All this avoids speaking of "good", "bad" states, which is very poor and does not correspond to the field in which we are gradually entering.

When using a form or a system of forms, it is necessary to look at the levels of equivalence and the states. Without this, we are no longer in control of what we are doing and serious consequences can occur, consequences which, sometimes, are not metrizable.

All states such as  $| K Sh Ph \rangle$  and those which contain this character warn that one could be faced with unforeseeable phenomena.

Note that to identify certain "magic" states, it was necessary to add dots • or holes o to

$| K Sh Ph \rangle$  ; thus we find:  $| K.Sh.Ph. \rangle$  and  $| KoShoPho \rangle$  and there are still others.

Exercise :

1) Check that the 4 shapes correspond to  $|K Sh Ph >$

2) That these two forms do not correspond to  $|K Sh Ph >$  nor even magic with additional characters.

3) That both forms respond to  $|KoShoPho>$

4) That the form responds to  $|K.Sh.Ph.>$

5) That the shape of Yin Yang responds to a magic called "Ying Yang magic"

6) That the three forms respond to other "magics"

Note :

- The following question "Are there several types of "magic"? is raised here.
- You shouldn't see magic everywhere; in Berry witchcraft, for example, there are many states | K Sh Ph, reversed Sh >.

We will see in exercise some colors of the differentiated spectrum.

- The shapes given below are always assumed to be oriented at NF; for example opposite.

We will therefore put the white and black circles to impose the NF. The eifs

are detected  
in the plane at the end of the shape placed at NF.

Note: Detection always at NF and in the plane.

### Exercise :

We give ourselves a rectangle of sides 6 and 10. We do not specify the unit of length.

1) If we say "in the center, we detect the node of life!" »

- a) Is it true ?
- b) Is it always true?

2) Since we didn't talk about unity, we could have chosen 5 and 3 as sides.

- a) Check that, taking as unit of length 32 mm, a rectangle of sides  
 $3 \times 32 \text{ mm} = 96 \text{ mm}$   
 and  $5 \times 32 \text{ mm} = 160 \text{ mm}$  does not have the life node in its center
- b) other hand a rectangle of side  
 $6 \times 32 \text{ mm} = 192 \text{ mm}$   
 and  $10 \times 32 \text{ mm} = 320 \text{ mm}$  has the life node in its center

3) At 10 and 6 it corresponds respectively to Y and W.

a) What can be detected in the center of the figure

opposite where the sides are like 10 and 6 -  
 and this whatever the unit -?

At 5 and 3 it corresponds respectively H and G.

b) Can we detect the life node in the center of the figure opposite?

Answers :

- 1)      a) Yes b) No
- 3)      a) We detect the node of life  
         b) The life node is not detected

Notes :

- In this exercise, we are confronted with the problem of unity. When 6 and 10 are announced, it is 6 n and 10 n where n is a unit. If we think of 6 n and 10 n above we will detect the life node in the center whereas we will not detect it if we think of 3 n and 5 n. But we have seen that if  $n = 32 \text{ mm}$  for example - other cases are possible - we are sure to find the node of life whereas we may very well not find it while doing 6 n' and 10 n' where n' is a unit fraction of the meter for example.

Let us point out that an Egyptian cubit makes it possible to have the node of life on this rectangle.

This goes even further but we will not discuss it in this course.

Moreover we saw that to 10 we had matched Y. It is no longer 0 10 as we presented it in the previous booklet. And even at 6 we have matched W and not the 0 0 6 etc... It seems that we are returning to the usual interpretation. It must then be understood that Faut alone is linked to a number, it contains the value of the number, but it expresses associated with other autioth or in certain circumstances, games linked to this value, in this case by the construction of sequences obtained by adding numbers.

One of the two Egyptian cubits allows for the rectangle of sides 6-10-610 to obtain the life node in the center.

“The world will only be  
saved,  
if it can be,

Andre Gide <sup>2</sup>

<sup>2</sup> André Gide (1869-1951) Nobel Prize for Literature in 1947

### Exercise :

Consider a magnetic needle placed on a round wooden tray; the pivot of the needle is placed with the center of the plate. The tray supports a copper circle.

Check, if the needle is well placed in magnetic North, that:

- 1) On the copper circle (of radius  $R$ ) the spectrum of the polarized body is detected - this without artifice -
- 2) On a concentric circle of radius  $2R$  - not shown - the aura is detected - this without artifice -.
- 3) The usual + and - polarities are detected
- 4) That everything is deflected  $5^\circ$  to the west with respect to the axis of the needle.

Advice : do not forget to drill the plate with a diameter  $>2R$  in the center right through.

- 5) We detect the vital field with the schin above.

From where one produces eifs starting from the magnetic polarities. If we replace the copper needle - on the transmitters that we will see later - by a magnetic needle, we must take into account the  $5^\circ$ .

- 6) If we place a bar magnet vertically, magnetic north at the top, and we put a wooden plate on it with a copper circle of radius  $R$ , the plate having a radius  $> 2R$ , then we check the same thing - The assembly corresponds to one of those of Baron de Reichenbach - (the tray as before must be drilled).

#### *IV. Special study*

Consider two circles with common center  $O$ , radii  $R$  and  $2R$ .

Suppose the circle of radius  $R$  is a polarized body and the circle of radius  $2R$  is an aura.

Let us draw as in the figure above the circles of radii  $R/2$ ,  $R/4$ ,  $R/2^n$  ( $n$  positive integer). These sets of circles correspond to an approach to the vital field whose 4 components are NF, SF, OF, EF

By drilling a hole in O, from side to side, allows work at the level of equivalence

"physical" ie H h AR Ts and avoid R WcH.

Here there is no need to impose the NF.

It is in the circles which pass through O that we draw the new circles. We could do the same route in the others but that would not bring anything new.

We can therefore make a round wooden tray, pierce it in its center, draw the families of circles of radius  $r = 1/2^n$ . By placing a needle with a radius between  $R$  and  $2R$  in the center, the eifs of the differentiated spectrum are detected and with a needle of radius  $< R$ , the eifs of the undifferentiated spectrum are detected.

Les eifs sont pour chacun des spectres émises au  $V_M^+$

Note :

The more circles of radius  $1/2^n$ , that is to say the larger  $n$  is, the more "powerful" the eifs are.

Naturally it must be understood that here the word powerful means that one detects farther from the wooden disc; the eifs being completely delocalized, there is no intensity associated with them.

## v. *The Fitness Field*

### Introduction

This experience was set up by Jean de la Foÿe to designate a field associated with a form that he called "Physical field". He is at the level of physical equivalence - H hA R Ts. It is often mixed with the vital field.

### Conditions for obtaining a good physical field

Let's start with a wooden disc placed on a material support which will represent the structure of the physical field - which we will see later -, it must have the polarized body, the aura, carry out the separation of the polarities, all with an orientation relative to the support and not relative to the natural magnetic field.

If a pencil is placed on the disc, the point at the artificial south and the other end in the center, it will have to emit an eif of the aura - if its length is sufficient -.

To set up the physical field Jean de la Foÿe started from the name of God - finally one of the names of God -: YHW H. He took the correspondence between autioth and regular numbers and polygons which gives:

Y     10     decagon

H     5     pentagon

W     6     hexagram

H     5     pentagon

He gives himself the circle as the unit.

We pierce the circle right through in the center Then we erase this circumscribed circle.

We can add the star pentagon but that does not add anything.

Revenons au cercle : On considère le O en haut. Plaçons le Yod sur l'intersection supérieure du cercle avec diamètre vertical. Perçons le cercle au centre.

On récupère du  $V_M^+$

On récupère l'eif indiquée en A

The diameter is drawn as in the figure, at  $40^\circ$  from the vertical diameter and the Waw is marked above.

Attention, the location of Faut on the drawing is fundamental.

The letter A is not to be marked on the diagram; it only serves to give an indication.

We draw the diameter as in the figure, at  $105^\circ$  from the vertical diameter and we carry the Hey.

Ici on récupère du  $V_E$

Let's make the 3 diagrams in one; and eliminate the circle.

- We double the Hey
- We do not need to impose the NF
- We drill in the center.
- We draw the horizontal diameter
- We find the vital field, that is to say that in particular we have the CD in the west and

One sees appearing what one calls the directing axes of the field of form.

Consequences :

- 1) so that if we remove the Hebrew characters we obtain the means of having the physical field.
- 2) Let's draw a circle that we drill in its center.

- 3) The NF is imposed.
- 4) By drawing the line at 60° from artificial north (NF), the field is oriented, otherwise the NF would have to be imposed.
- 5) Here it is only the differentiated spectrum.
- 6) If we draw the axis of V' (VE, V'M) the vertical above the center is + and the axis of V^+ (V^+ E, V^+ M) is +.

A control must be treated on a + axis so in this case it is preferable to draw the V axis.

- the circle is erased.
- the spectrum of the polarized body is only detected by placing a concentric circle of radius  $R/2$  with a needle  $< R/2$  - if  $R$  is the radius of the starting circle -. We must therefore use a needle of radius  $r$  such that  $r < R/2$  if we want to detect the differentiated spectrum.
- We can leave the circle of radius  $R$  it does not interfere with the eifs.

Note :

This scheme is not emitting as well; we gave it to put in mind the provisions of the eifs of the differentiated spectrum. The small central circle is worthless.

At one place we see on a radius "Chartres". This is the so-called eif of Chartres - in memory of Chartres Cathedral where Jean de la Foÿe had discovered it He designated it by  $Z^+M$ - There is also  $Z'M$

Are also carried on 4 rays, respectively the 4 forms characterizing the vital field.

The associated eifs correspond to what these forms placed at NF emit, that is to say:

By symmetry with respect to the center we have  $Z^+E$  and  $Z'E$  respectively.

There are the eifs of the undifferentiated spectrum  $Z^+$  and  $Z'$ .

Jean de la Foÿe, starting from YHWH, managed to build a field - Physical field - which has the interesting properties of generating the 2 undifferentiated and differentiated spectra.

God's name is not always YHWH; it suffices to consult the Torah to be convinced of this.

By using other words, other fields are possible which do not give the eifs of the tree trunk.

The emitting plate of undifferentiated and differentiated spectra

We will make it in 3 cm thick wood, pierced in the center right through. Two very pointed copper needles are made, one of radius  $r$  and the other of radius  $2r$ .

needle

^tray

The board is circular; a circle of copper wire with a radius of  $2R$  is glued, such that  $2R$  is slightly less than the radius of the disc.

Then we burn the physical field to disk.

At  $V^+M$ , we weld to the circular copper wire a finer wire where we will detect the eif indicated by one or the other of the needles.

We carry on the edge of the disc angles of  $10^\circ$  in  $10^\circ$ , the  $0^\circ$  at the top as well as the 24 eifs of the differentiated spectrum and the 12 eifs of the undifferentiated spectrum on the circle of radius  $R$ . We will always operate only with one needle.

We have  $r < R$ .

## Erratum of the 5''' booklet (page 2)

A The FFV is composed of 3 segments OA, OB, OC such that OA is vertical, OB=OC and the angle BOC =120°.

The angle of OA with the plane BOC is equal to 33°.

OA = ip x OB where ip is the Radian number

ip ~ 1.324...; we can take 1.32 as a value, the form will be correct.

i. *The eifs of the undifferentiated spectrum and of the differentiated spectrum Forms called "canons"*

It is a wooden stick, circular or square in section.

cH YYM

Let us see for example the Hebrew words which mean to live, to exist and 600 which means life, food, subsistence.

Note: For 8 10 10 600 we will take 8 10 10 24 (explanations later).

Let us wear on a stick 8, 10, 5 or 8, 10, 10, 24, grooves allowing to place the lengths 8, 10 etc...

The unit can be arbitrary.

We will hold the stick at one end - that of length 8 - and point it at the plant to detect; that for which it is necessary to employ an artifice.

It is these two types of sticks that will intervene for the approach in the study of a plant.

Thus, remembering what we said in the first booklets about the detection of the polarized body or the aura of the tree trunk, we can:

- either press the thumb of the free hand on the folded little finger, the hand pointing towards the sole,
- any leaf between the thumb and the index finger,
- either lean the plant if possible,
- either take a witness and put it in a circle where the NF - SF has been imposed.
- or finally hold an 8+10+5 cannon
- or an 8 + 10 + 10 + 24 cannon

About the cannon it is necessary:

- hold it by part 8,
- orient it by tending it towards NF.,
- otherwise, we can ignore the orientation and carry:

on 8, 10, 5 the autioth cH, Y, H or

on 8, 10, 10, 24 the autioth cH, Y, Y, M.

- we are obliged, for the realization of certain sticks, if one of the endgames is K, M, N, Ph, Ts to count it as if it were not in the endgame. Note: on the Letters-numbers table, the numbering is 10, 20, 30... starting from 10. Here we will count 10, 11, 12...
- To avoid the orientation of the NF of the stick, one can plant vertically in certain grooves a small copper nail.

It is seen that the handling of the sticks must be carried out with caution.

Problem : We consider an emitter of Bc (undifferentiated). It is sent by a thread on a wooden prism.

1) What do we observe on the other side of the prism?

Y 2) We build a form in copper wire, for example as shown opposite I (warhead) and place the NF on the axis above. What can be observed in the inner /  $\hat{I}$  \ axis?

/ | \ 3) The detected eif is called according to the terminology of Jean de la Foÿe: eif i I of Chartres (it is detected under a vertical warhead). What does it do on the I eifs of the undifferentiated spectrum?

6

4) It is sent on a wooden prism. What do we observe on the other side of the prism?

5) By an appropriate assembly, it is combined with the undifferentiated Bc. What do we get?

| 6) Does an ogive of this shape give the eif of Chartres?

m

7) We carry out the assembly below, that is to say 2 warheads having the same axis. We imposed the NF. Do we still have the Chartres eif?

.

8) What are the M and E components? The component M is detected with the form

placed on a cylindrical pendulum. The component E with the form

The Hebrew word (found by Jean de la Foÿe) corresponds to the eif of Chartres (Haretz) the hA R Ts?

Ha

r have

final Tsade Reisch Aleph

27 (900) 20 (200) 1

Reminder: Hebrew is read from right to left.

Here the Ts, although final, is counted normally (27 and not 18).

Build the corresponding cannon. Check that oriented NF-SF it emits the Chartres eif - hold it by the side of the hA -.

Can the barrel be made direction independent?

Answers :

1) We find the undifferentiated eifs.

- 

many sticks can be made from Hebrew words. You just have to know its usefulness.

Problem : Consider the transmitting disk. We put 2 identical needles allowing each to emit in differentiated. One is at  $320^\circ$  and the other at  $60^\circ$ .

- 1) What do we get back at  $V^* M$ ?
- 2) We always put a needle at  $60^\circ$  and the other at  $140^\circ$ , what do we get back?
- 3) We now put 5 needles of the same length and length equal to that of the previous ones: at  $320^\circ$ ,  $60^\circ$ ,  $105^\circ$ ,  $140^\circ$  and  $285^\circ$ . What do we recover? What does it remind?

Answers :

- 1) We recover  $V'M$ . This  $V'M$  ALSO makes it possible to load a witness better than with a single needle on the  $V'M$ -
- 2) We have  $V'E$ -
- 3) At the start,  $V'M$  APPEARS and the whole spectrum on the right and on the left in  $M$ , then THE  $UV\hat{I}E$ - After a while, everything collapses and appears the first field of Taofel.

Then

|   |          |   |
|---|----------|---|
| 1 | ZDZZIZIZ | 1 |
| 2 | ZZZZZZZ  | 2 |
| 3 | ZZZZZZZ  | 3 |
| 4 | ZZZZZZZ  | 4 |

We don't go any further.

This recalls what happens at the end of % hour after the Sprink device is switched on - a device that allows, among other things, to carry out "catalysis without catalyst" -.

Notes :

- 1) This exercise allows you to become aware of other eifs called by us "Champs de Taofel". We will address them in the 2nd year course .
- 2) In general, 2 needles should not be used simultaneously on the same transmitter plate, nor on two such connected plates.

We tried to compare the eifs by this process; Jean de la Foÿe wanted an addition-like comparison of vectors; it does not work. This is easily checked because we sometimes leave the EFF spectrum to obtain Taofel fields or something else.

Problem : We consider again the triangle  $40^\circ$ -  $60^\circ$ -  $80^\circ$  whose respective vertices are B, C, A, M the midpoint of BC,  $C_x$  the half-line of angle  $(C_x, CB) = 15^\circ$ . It intersects the bisector of CB at T. From T we draw the lines  $T_y$  and  $T_y$  respectively perpendicular to AC

and AB. We pierce the plane in T. We see immediately that  $(T_x, TM) = 105^\circ$ ,  $(T_y, TM) = 60^\circ$  and  $(TM > T_z) = 40^\circ$ .

- 1) Observe that both inside the triangle and outside there are no polarities or Vital Field
- 2) Draw the line parallel to BC passing through T. What do we observe?
- 3) We draw the circle circumscribed to the triangle ABC and the circle with center T and radius CT. It can be observed that the figure emits what are called Arkhams and Mahkras <sup>1</sup>. By removing the triangle ABC, we still have some Arkhams and Mahkras.
- 4) By taking a pencil placed on the plane, the end not sharpened in T and directed along a radius (the length of the pencil greater than or equal to CT), he emits the eifs of the aura to the SF.
- 5) Can we have the undifferentiated spectrum?

Answers :

- 3) There is a Vital Field. The portion of the plane to the left of CA and bounded by extended BC and BA is negative. The portion of the plane to the right of BA and delimited by CA and extended CB is positive. Ty in the sense of Ty is positive in a portion that begins a little outside triangle ABC.
- 5) Yes. If you want to have it with the same needle, you have to take it with a length less than or equal to the length less than or equal to TM.

Consider the homothetic triangle of ABC, in the homothety with center T and ratio 'A. We can have an undifferentiated eif with a needle of length less than or equal to the length of the segment carried by the ray issuing from T and of which one end is at T and the other obtained as the intersection of this ray with the side of the homothetic triangle of ABC in the dilation noted above.

<sup>1</sup>This will be seen in the course of 2<sup>ème</sup> year

Problem :

Consider the shape consisting of two crescents joined in the back. It corresponds to an eif<sup>2</sup>.

Make a cylindrical pendulum on which it is carried on the side surface.

- 1) Check that this eif is undifferentiated. Give the precise angle of emission when using the transmitter disc.
- 2) Check that we find  $Z^+$  on the star of David whose highest peak is pointed above, the fleur-de-lys of the kings of France, the Ermine of Brittany.
- 3) If the Star of David is vertical, not pointed, do we detect the  $Z^+$  and where? If the fleur-de-lys, the ermine of Brittany are vertical in the usual gaze position, can the  $Z^+$  be detected ?
- 4) If these shapes are in a horizontal plane, how do you get the  $Z^+$  ?
- 5) It corresponds to the Hebrew word DBR (Dabar)

RBD

D

|          |       |        |
|----------|-------|--------|
| Reisch   | Beith | Daleth |
| 20 (200) | 2     | 4      |

Make a cannon 4 - 2 - 20; find by which extremity one detects Dabar. (Should NF be oriented?) If so, what can be done with the cannon to impose NF?

- 6) The  $Z^+E$  corresponds to the shape . Where do you find it on the transmitter board? Same question for the M which corresponds to the form

<sup>2</sup>Discovered and named  $Z^+$  by Jean de la Foÿe.

7) We make arrive by 2 wires, one in front of the other the following eifs

Saw and N  
Vi and R  
O and UVi  
BC and J  
IR etl  
V<sup>+</sup>M and V'E

Show that we detect Z<sup>+</sup>. To make a success of the experiment it is good to take 2 identical emitter trays. Their output wires must not be coupled.

8) Check that this eif is emitted by the palm of the hand and the mouth when the eyes are open and by the top of the hand if the eyes are closed.

Answers :

1) 131°

3) Yes and vertically above these shapes.

4) For the star of David, the fleur-de-lys and the ermine of Brittany, we impose the NF. O

On the Star of David, it is detected vertically to the point. On the two other forms, it is found in the plane, on the axis of symmetry of the forms, above them.

2 4

SF BTnT'iTmBT'iTiTBnT™.

We detect Dabar on the side of the end 4. If we plant a small point in the groove between 2 and 20, we impose the NF. It is good to wear the numbers 4-2-20 on the barrel so as not to work on 2-1-10. The Z<sup>+</sup>M at 251° and the Z<sup>+</sup>E ARE DETECTED by symmetry with respect to the center of the transmitter plate.

"He who does not shout the truth  
when he knows the truth  
becomes an accomplice  
of the  
liars  
and  
of the  
counterfeiters! »  
Charles Peguy <sup>3</sup>

<sup>3</sup> Charles Péguy (1873-1914) born in Orléans - He entered the Ecole Normale Supérieure where he had as master Bergson - He died on the front on September 14, 1914.

## *II. eifs "Amplifiers"*

### Remark

First of all, remember that since eifs are not localized, talking about amplification makes no sense. There is no "greater than" or "less than"...

Yet effects on living beings can be compared, for example the disappearance of an illness: we can measure a shorter duration.

Thus we will say that the eif or eifs used were "more intense". But this is an excess of language.

And the pendulum will be taken as a convention that it rotates faster, that the sensation at the wrist is more brutal when it is "stronger".

You always have to know what you are doing and question tacit knowledge.

### Ways to "amplify"

We will only name a few.

The undifferentiated and differentiated spectra are considered in the eifs.

Care must be taken to ensure that the amplification process does not change the nature of the eif, nor its state.

### 3) *Method of André Philippe*

André Philippe had the idea of placing a magnifying glass on the output wire, that is to say a biconvex lens. The larger the lens, the stronger the amplification.

**b) The wire is placed between two parallel mirrors**

The mirrors can have a certain angle between them.

vs) **Use of electric current**

En  $V_M^-$  et

$V_E^+$  the wires are not welded to the copper wire but a small insulating sheath separates them at these 2 points of the circle.

The higher the battery voltage, the greater the amplification.

It was a continuous current since a battery was used.

It is also possible to amplify from an alternating current. The assembly is as follows:

Here the welding points are at NM and NE. One can choose the capacitor so that there is no short circuit. The higher the AC voltage, the greater the amplification.

d) Other editing that increases the amplification

Problem :

Consider the shape of the Z<sup>+</sup> but inserted between 2 vertical lines <sup>4</sup>

Make a cylindrical pendulum on which it is carried on the side surface. It corresponds to an eif.

- 1) Check that this eif is undifferentiated. Detect her on the board.
- 2) It corresponds to the Hebrew word Sh M ch A (Shamch'ah: listen-listen)

<sup>4</sup> Discovered and named Z' by Jean de la Foÿe.

0 ffl C

5) Find the position of Z'M on the board and that of Z'E-

4) Z'M is detected at  $290^\circ$  on the transmitter plate. Z'E au symmetrical with respect to the center.

Naturally, the orientation must always be imposed on the NF.

This form emits something at the NF but it is not the  $\hat{VIM}$ - If we work in

RW cH, there is the eif of the stick on which one carried Sh DYM (Shadaim) (the M on O stick is counted 13).

We have an eif which is placed between RM and IRM like this RM      IRM  
and this eif is in the state | Sh DYM >

Let's take the shape

<sup>M</sup> This is the eif of the stick on which RWR Ts (Tsoror but inverted) has been worn.

Notes :

® “the word Tsoror is Ts RWR because you have to hold the stick by the Ts and direct it towards the NF

- There is no | K Sh Ph >.
- Ts RWR means kept, bound, bound, bound, retained, fixed, sequestered, man without wife or wife without husband, bundle, bundle.
- The Ts must be 18
- This form is found on the tablets of Easter Island.

Note : When using geometry and its figures, it should be remembered that the properties of figures are those whose lines have no thickness. In the domain of forms, lines have thickness; it is needed to determine eifs and states.

Problem : We give ourselves the triangle of angles 40°, 60°, 80°.

- 1) Find the position to impose on the NF so that it emits the right schin above. Does it emit the Vital Field under these conditions?
- 2) We put it in a circle much larger than the triangle, the triangle towards the center. The NF is imposed on the circle. Check that the schin is then detected above the triangle and the 4 components of the Vital Field.
- 3) We return to the conditions of 1). Is there a point in the triangle which, pierced, causes the triangle to emit the Vital Field?

Answers :

- 1) See diagram for NF.
- 2) Nope

- 3) Yes. If A, B, C are the respective vertices of the angles  $80^\circ$  -  $40^\circ$  -  $60^\circ$ , and Cx the half-line forming an angle of  $15^\circ$  with CB, i.e.  $(Cx, CB) = 15^\circ$ . Let M be the midpoint of CB. The perpendicular bisector at M intersects Cx at T. T is the point sought.

O

### Exercises :

- 1) Detect on a plant the eifs marked on the drawing:

Note: we also have the Vital Field, and the right schin above.

- 2) What happens if we uproot the plant?  
 3) What happens if we add soil around the plant?  
 \*4) If you cut a plant at ground level, what happens?

### Answers :

2) The life node disappears immediately. Z and Z' detect each other again and a little and slowly disappear just like the eif of Chartres

(M)

- 3) The node of life, if the level of the ground is not too high compared to the initial level, is always detected on the surface of the ground. If the level is too high, it is no longer detected.

\*4) The life node, Z and Z' disappear.

Exercise :

A circuit in the form of a life node is made out of copper. O is a center of symmetry. These points A<sub>1</sub>, A<sub>2</sub> and A<sub>3</sub> are such that A<sub>2</sub> is on the axis of symmetry yy' and A<sub>1</sub>OA<sub>2</sub> = A<sub>2</sub>OA<sub>3</sub> = 120°. Resistors R<sub>1</sub>, R<sub>2</sub>, R<sub>3</sub> are mounted as shown in the diagram and their values are R<sub>1</sub> = R<sub>2</sub> = 125 kQ and R<sub>3</sub> = 100 kQ. The circuit is connected to 220 V AC.

Check that we have eifs that come out vertically from the assembly. In addition, check that these eifs are of variable "intensity" and of variable nature, this on a periodic basis.

Exercise :

We take the form opposite placed between the NF and the SF Find your eif?

Answer : It has a differentiated eif at 230°. It has at E, when placed between 4 vertical lines, an eif at 50°.

#### IV. A musical instrument: the violin

Many violins respond to | K Sh Ph >. We detect the right schin above the table; roughly vertical to the web <sup>5</sup>. If the soul is removed, the schin disappears, the | K Sh Ph > also.

On a violin we also detect a vital field.

<sup>5</sup> Piece of wood placed between the top and the back and whose role, from a rational point of view, is to support the tensions between the top and the back.

When the instrument is played, transfer phenomena between instrumentalists can occur through the orchestra, often via the conductor.

Each violin must be studied separately. One should not deduce too hasty laws on the vital field, the eifs, the schin, the states etc...

Let's say that we can find even modern musical instruments that emit at levels other than EFF, for example what we have called the fields of Taofel (C.de T.). For example, the device designed and assembled by the Bachet brothers called "Le cristal" emits at high C. de T.. On the other hand, if you play the music of J.-S. Bach on it, it no longer emits these C. de T.. So if you want to use this device for the quality of its eifs, you have to create for it music.

We could still say a lot of things about the violin, but it involves concepts that are not in this course.

But, violin making, through the study of eifs, states, is presented in a completely new light <sup>6</sup>.

Let us point out that a viola d'amore with an angel's head sculpted after the pegs emits the knot of life through the mouth of the angel. We find twice the knot of life on this instrument of 14 strings of which 7 resonate by sympathy and 7 are played.

<sup>6</sup> This development on the violin was taken, with the authorization of the author, from Vladimir Rosgnilk's work "The Emergence of Enel or the Immersion of Landmarks - Introduction to the Study of Forms and Fields of Choerence" (Volume 2)

With vital field, right schin pointed in the middle, it is also necessary to add the harmonics of this form. We will see shortly the concept of form harmonic.

## A. *Form*<sup>1</sup> harmonics

An important notion is that of the “harmonics” of forms. Before tackling it, let's see some additional information relating to prehistoric objects.

Consider the statuette known as “The Venus of Lespugue”. Many such female-looking figurines were called Venus, which is somewhat derogatory as it is usually assumed by RBBs that prehistoric men were more boeotians than human beings. Let's see one of these.

Lespugue is a small town in the department of Haute-Garonne, France. The region is hilly and harmoniously composed of crops, meadows and woods. Only one roughness is in the landscape: the notch dug by Save, a small river with fresh water born on the plate close to Lannemezan and which will be thrown in the Garonne.

Lespugue was made famous by a statuette discovered in 1922 by a prehistorian, Count Saint-Périer. It is mainly thanks to his wife that the discovery could be made. Indeed, she went deeper into the cave in which her husband, herself and helpers were digging and she noticed a mound covered with grass. She made a superficial sounding there and found that the very hard ground in this place had not been disturbed like all the rest of the cave.

Following his remark, the workers begin to cut the topsoil, which is 25 centimeters thick. zBelow appears a layer of hearth ash, in which there are some flints. A rock is embedded in it; the workers free it. One of them suddenly brings back an object which is at the tip of his pickaxe. He is immediately examined; it is a prehistoric female statuette, from the Aurignacian period in ivory, comparable to the Venus found at Brassemponty, in the Landes. The blow of the pickaxe broke the object into two pieces; the left arm is missing as a result of an old fracture. The object is so fragile that light scales stand out from its surface. This statue will remain incomplete, but regardless, the symmetry of forms is so remarkable that it is easy to make a perfect reconstruction. Mr. Boule, paleontologist, with whom R. de Saint-Périer is very close, is enthusiastic.

The statuette is small: 147 millimeters high by 60 wide. It is carved in a fragment of ivory from a mammoth tusk and the artist has succeeded, despite the extreme hardness of the material, in a work that denotes both an admirable sense of sculpture and an unparalleled technical skill.

<sup>1</sup> This text appeared for the first time in Vladimir Rosgnilk's book “The Emergence of Enel or the Immersion of Benchmarks”. It is reproduced here with the permission of the author.

The head is small, ovoid. No feature of the face is marked (one can suppose that the nose and the mouth were represented by lines of color). The hair, indicated by parallel notches, extends back to the spine of the shoulder blade and covers almost the entire face in front. The thorax is flat, but the breasts, attached very low, swell and spread out gradually until they form enormous skins, resting on the stomach, itself framed by prominent hips. The legs are short, the feet barely outlined.

HP Eydoux remarks: "A singular garment, made up of narrow bands and resembling a kind of loincloth, covers the back of the legs".

He adds: "seen from the front, the statuette is made of a superposition of spherical masses assembled with a keen sense of rhythm and balance, according to a refined interplay of volumes and patterns. The anatomical reality is deliberately distorted in favor of a true abstraction".

Eydoux asks himself the question of why such a shape; he does not find an explanation but feels that it is necessary to think outside the box to manage to grasp the motivations of prehistoric men. He asks himself: "Was prehistoric art art for art's sake? Admittedly, it could have been a simple game, born of the forced leisure of long cold periods, during which man decorated the walls of his shelters as well as his everyday objects. But there is also no doubt that religious concerns or magical rites have, to a large extent, inspired his works".

Why is the Venus of Lespugue said to be of opulent forms? Concern for realism say some. But then, in this case, wouldn't the artist have represented the features of the face and indicated the arms and legs in a less schematic way? It is very voluntarily that the sculptor gave to the breasts, the belly, the hips a disproportionate and unreal importance, while giving to the other parts of the body only an almost schematic value. He highlighted with systematic complacency the attributes of femininity. He ends his article thus:

"It is difficult not to see there a work that symbolizes motherhood, fertility. The Venus of Lespugue is the ancestor of the mother goddesses; it exalts procreation".

This last point had been pointed out many times by paleontologists, the magical character much less. The two points of view can also be associated. The magic character has nevertheless been sensed by prehistorians. Chaumery and Bélizal who worked in the field of eifs from 1930-1935 have, in their work, pointed out the importance of arrows drawn on the profiles of animals painted in caves. We find in this work the following: "Bold explorers, like Norbert Casteret, have

discovered roughly sculpted in the caves of the Pyrenean subsoil the evidence of this magic which allowed hunters of prehistoric times to first paralyze game in order to then be able to capture it more easily. To achieve this goal, they drew on the walls of their underground dwellings the shape of the coveted animal and previously spotted in one of the previous hunts, then a stylized hand usually placed on the side of the animal, marked the will, the power of man over his victim" and Chaumery and Bélizal report what Casteret writes on this subject "The Aurignacians and Magdalenians, essentially hunters, sought to promote the success of their hunts by having them preceded by ceremonies whose significance appears to us better and better as prehistoric discoveries are made. They represented the animals they wanted to kill, then, during the sessions of magic spells, traced wounds on these drawings, thus killing the animal in effigy, to ensure, on the day of the hunt, the real capture. of the beast, previously bewitched".

"Thus are explained," continues Casteret, "the holes, arrows, axes, clubs which are seen in many drawings of animals." Sometimes the intention of the primitive hunter is even more explicit; the animal is shown falling into a trap, into a net, succumbing to stoning. This theory seems above all indisputable when one considers the lions and bears of the Montespan cave which are riddled with blows of spears and arrows aimed with precision in the vital parts and with so much violence and relentlessness that, sometimes, the statues collapsed". Chaumery and Bélizal then speak of the "command baton" which was quite simply a pendulum.

This pendulum had the particularity of carrying animal drawings engraved on its walls. Usually constructed of antler or reindeer bone, the command stick was a perfect witness detector for hunting the animal.

Straight or angled, pierced in its upper part with a hole which was used for the passage of a cylindrical wooden or bone rod (a rod that the man held horizontally in his hand by one of its ends), the stick-pendulum would revolve around this support as soon as the hand of the other arm, forming an antenna, picked up the reindeer radiation (if it was a question of pulling a reindeer) and this regardless of the distance where the animal was .

To spot a game, the Magdalenian simply had to eliminate in his brain all the drawings of animals finely engraved on the stick, to keep only the one that was the object of the hunt (mental solution). »

<sup>2</sup> It should be noted that they also used duplication, which saved them unnecessary outings.

Note that there is no "reindeer", "mammoth" or other radiation. The hand, in the human being, has an intense character of localization. Features are localized for the most part. But the human brain, by its character as a fractant <sup>3</sup>, makes it possible to “ape” these functionalities and transport them, thanks to the hand on the drawing of the animal; or again, one can be in contact with the enels <sup>3</sup> attached to the animal-entities. This statuette called the "Venus of Lespugue" like the Venus of "Willendorf", the hips are very widely suggested. These statuettes, one might think, were used for magic ceremonies. They could even be in transfer with the female Enel <sup>3</sup>. The human beings of these prehistoric times were no doubt sensitive to delocalized notions. At the level of a woman's pelvis, the rounded shape of the hips (seen from the front) is reproduced approximately 3 times a few centimeters from the skin, as in the diagram below. These delocalized forms will be called harmonics of a form which is here that of the hips. The whole body has no harmonic, it vanishes as soon as we leave the level of the hips.

The role of the so-called “Venus” statuettes with their *full* hips was, thanks to

(// \ magic manipulations, to amplify effects

I dd of these manipulations using the

\\ \ \ \ \ harmonics of the shape and to do this, we

accentuated the width of the hips vis-à-vis the rest of the body, so as to hang up the first or even We find harmonics in the form which is the violin, this for the table of the instrument and in its widest part. The viola, the cello can have harmonics, but it is rarer. A man's body at the hips has no overtones.

Let's come back to the concept of form: a painting for example: the work, already ambiguous by its function, is even more so when we try to remove it from its original atmosphere, from its primitive function (which is what every collector does). Indeed, what was it used for and what is it used for now? But it is ambiguous when one tries to analyze it as an isolated object! Were we to fully describe this certain order found in a painting, we would still have no guarantee, either that this order is the primary cause of our emotion, or that we could, with the help of this order, our turn a beautiful painting.

<sup>3</sup> Fractant, Enel: concepts that will be presented in the 2nd year course .

<sup>6</sup> This is another representation.

representation as in the case of a house where one can choose between the house as the reunion of its rooms or the house as a whole.

Maurits-Corn élis Escher, born in Leewarden in 1896, in Holland, led a discreet life, entirely dedicated to hard work in the arduous discipline of drawing and graphic arts.

The graphic techniques he practices are classic: wood engraving with a penknife, lithography, engraving on linoleum. His skill is noticeable in the engraving in several flawless repeated colors, which is generally only within the reach of professional engravers. The great event in Escher's life was the discovery of his work by men of science. Following his participation in a congress of mathematicians in Cambridge, an important publication in the journal "Life" was devoted to him. In 1954 he had an exhibition in Amsterdam and another in Washington. All of Escher's thought revolves around the idea of reducing space to the plane. Indeed, in this operation which consists in flattening the objects and nevertheless making them stand out as if they were in volume, there are a number of possibilities of establishing different links between one object and another from the moment when it is amputated by one dimension.

In perspective an object in a given environment, itself rendered in perspective, will not have the same eifs nor the same states as in direct vision. One can wonder if there would exist mathematical transformations making pass from  $R^3$  to the plan which would make it possible to preserve the eifs and the states. We do not yet have an answer to this question. One can for example associate with the sphere pierced with holes of Chaumery-Bélizal a figure on a plane which has the same eifs. We will give the diagram in the next booklet.

About drawing using perspective, we will turn to Escher. Albert Flocon met Escher who, in particular, described this to him about his engraving "Ordre et Chaos" <sup>7</sup> from 1950.

“At the center of this engraving is a partially rWS starry dodecahedron enclosed in a translucent sphere as a symbol of ordered beauty.

according to mathematical laws. In this shiny bubble is reflected a collection of heterogeneous debris, bits of string, broken glass, broken pipe, cork, etc... It was difficult for him to find debris that was both at the limit of the object Again recognizable and whose appearance he must still be able to render. Escher brushed against the border of the informal here by approaching it from the side of the form; indeed, what can be the

<sup>1</sup> This is reproduced in most works on the work of MC Escher.

destruction of a lid of a yogurt pot so that both the latter and its destruction can be recognized?  
»

In the plate "Tetrahedral Planitude", the painter has done so that we accept the possible existence of this micro-world where the buildings are superimposed in a dizzying pile. Whichever way you look at this board, it is always straight. We could also speak of the "Three Spheres", an engraving from 1945.

Escher drew crystal lattices, regular and uninterrupted fillings of the plane; we have disturbing compositions. Here, the notions of form and background disappear because they both fulfill these two functions successively: for example, the black riders that fill the sheet are transformed into white riders on a black background when we fix our attention on the emptiness that separates them. As a result, the entire line drawn on

A number of Escher's prints are called "metamorphoses". We see how vague forms (shapeless forms thus called by J. Ravatin) are converted into well-defined and known forms and vice versa. A grid becomes a chessboard whose squares are transformed into black and white lizards, which themselves are reduced to hexagonal cells, which become the cells of a hive; the motif continues with bees emerging from these cells; these bees in their steady flight cut out words that take the shape of oncoming fish. But the black background which supports the fish is transformed into a flight of birds which, in turn, freeze in a formless network which little by little becomes a cubic network, and this cubic network becomes a city with a Mediterranean look. Towers of this city advance towards a chessboard; it transforms again into formless black and white shapes to gradually become squares and everything begins again. It is interesting to note that in these descriptions only easily recognizable forms are mentioned, but that formless forms are neglected; although the author recognizes them as fundamental, since Escher used them.

Escher's technique is very interesting, because it clearly expresses the emergence

Day and night

of a form based on formless forms. If we test, for example, an engraving like "Day and Night", we find, if we do not try to look at either the day part or the night part.

a state  $|K Sh Ph \rangle$ . This state is  $|K Sh Ph \rangle$  not to express a total inconsistency but a lack of understanding.

Consider another engraving by Escher: "The drop of rain ". The drop of water can be a support of reality and the leaf, variations around this support, or the leaf is the support and the water drop is supported (this is the usual view \_j a drop is on the sheet, the

form is in the Universe). It is the same for the engraving "La mud ".

In Escher we find representations of the emergence, of the escape of landmarks through the passage from recognizable form to informs him.

In Escher we find a duality; it appears between pieces of the same painting. For example: in "Day and Night" A (everything relating to the day) comes out of B (everything relating to the night) but B comes out from A.

Thereby (A comes out of B) to realize B  
(B comes out of A) to realize A

Two sets A and B are mentioned; they are not really drawn, and A is evoked because B is felt and vice versa. We are faced with a dynamic duality between A and B <sup>9</sup>

but for that it is necessary to place oneself in the case where one has the state  $|K Sh Ph \rangle$  (which absolutely does not mean that each time we have a dynamic duality, we will have a  $|K Sh Ph \rangle$ ).

This one comes because we looked before A and B and then we went to the board forgetting A and B <sup>1J</sup>. There remains the incomprehension of what was felt before in relation to "Ascent and Descent" in which a staircase is closed; it constantly rises to the right and similarly descends to the left.

P

But the other point of view is: from the drop comes the leaf. The drop encloses the depth landmarks, as well as emergence. If we want to consider the two points of view, we will say: The leaf is the support of its emergence or the drop is supported by its extension, hence the local is the support of its emergence and the global is supported by the localization.

<sup>y</sup> In reality, the dynamic duality occurs between (.4. sort of B) and (B sort of A) (C oncept to be seen in the course of 2 year).

We can also consider that A is to B what B is to.A, that is to say (.AB >.B,A) which has an aureolar, but this aureolar is not the dynamic duality (Concept to be seen in the course of 2"" year).

Obviously this staircase cannot be realized in  $R^3$  but on the plane, with the technique of Escher, if we consider the dynamic duality realized, the plane image can be used.

The “Belvédère”, “Perpetual Movement”, “Up and Down” lithographs are of the same type. On the other hand, in the “Encounter” and “Reptiles” lithographs (presented at the end of the booklet), the concept of emergence is rendered.

## B. Study on the Golden and Radiant Numbers

### 1. The Golden Number

With decagons, pentagons (polygons insufficient to balance the physical field) appears the Golden number.

Egyptian constructions are based on the golden ratio.

It inverts the R and the Vi of the polarized body, which makes one think that one falls on | K Sh Ph with inverted Sh >.

To check this, you have to build it. For example, we draw the branch with positive abscissas of the curve  $y = 1 + \frac{1}{x}$  which is cut by the line  $y = x$  which gives  $x^2 - x - 1 = 0$  therefore the x

positive root is  $(p = \frac{1 + \sqrt{5}}{2})$ , 1<sup>th</sup> golden ratio.

We will see later how (p inverts the polarized body, and does not touch the aura.

We will distinguish a sequence  $b_1, b_2, \dots, b_4, \dots$  for  $(b_n)$  where  $b_n$  is the general term.

Consider the sequence  $b_n = 1 + \frac{1}{b_{n-1}}$  with  $b_1 = 1$

It can be demonstrated that

Fibonacci sequence: it is such that  $u_n = u_{n-1} + u_{n-2}$  with  $u_1 = u_2 = 1$  i.e. 1, 1, 2, 3, 5, 8, 13, 21... It is called a sequence of Fibonacci. It is obtained by the recurrence relations  $U_n = u_{n-1} + u_{n-2}$  - We will call Fibonacci type sequences those for which  $u_1 > 0$ ,  $u_2 > 0$  and  $U_n = u_{n-1} + u_{n-2}$  -

Let's write 1, 1, 2, 3, 5, 8, 13, 21 and, below the same, shifting one row

1, 1, 2, 3, 5, 8, 13, 21

Let's make the ratios of 2 terms one below the other. We obtain :

$\frac{1}{1}, \frac{1}{1}, \frac{2}{1}, \frac{3}{2}, \frac{5}{3}, \frac{8}{5}, \frac{13}{8}, \frac{21}{13}, \dots$  this sequence converges and tends towards (p. 0 00 1

The Fibonacci sequence is as important, in the field of forms, as the golden ratio (p

The sequence of fractions which tends to (p can be used to construct certain forms.

We pass from the sequence  $(u_n)$  to the sequence  $(b_n)$  by setting  $u_n = 1 + \frac{1}{b_{n-1}}$  or  $b_n = \frac{1}{u_n - 1}$  so

$$b_n = 1 + \frac{1}{b_{n-1}}.$$

Note : The graphical representation of the

function  $y = 1 + \frac{1}{x}$  is,

as is known, an equilateral hyperbola.

To the term  $b_i = 1$  corresponds the point  $M_i$  of the curve  $H$  whose abscissa is 1

and the ordinate  $U_2$ .

To find  $U_3$ , we transfer  $U_2$  to the abscissa by leading through  $M_i$  the parallel to  $Ox$  to the point  $P$ , located on the first bisector; the parallel to  $Oy$  led by  $P$ , meets  $H$  at point  $M_2$  whose ordinate is  $U_3$ ; to get  $U_4$ , we transfer  $U_3$  to the abscissa by leading through  $M_2$  the parallel to  $Ox$  to the point  $P_2$  located on the first bisector, etc... We see in the figure that the vertices  $P$  of the broken line  $M_1P_1M_2P_2M_3P_3...$  are located on the first bisector and approach more and more the point common to  $H$  and to this bisector.

Exercise : Build this figure and keep only the broken line - we will erase everything else, even the  $H$  curve -

- 1) what do we detect in the center?
- 2) We pierce the center of this spiral made by a broken line. What do we detect?

Answer :

- 1) | K Sh Ph with reversed Sh >

By connecting the center of the spiral by a filament to the center of a "tree trunk", we verify that the polarized body rotates  $180^\circ$ .

- 2) This state disappears. It is also checked, as in 1) that the polarized body of the tree trunk is not disturbed.

Let's go back to the Fibonacci sequence  $(u_n)$

$$u_1 = u_2 = 1$$

$$u_3 = u_2 + u_1$$

$$u_4 = u_3 + u_2$$

Properties :

$$1) u_1 + u_2 + \dots + u_{2n-1} = u_{2n}$$

$$2) u_2 + u_4 + \dots + u_{2n} = u_{2n+1}$$

$$u_n = u_{n-1} + u_{n-2}$$

Reminders : Let  $(t_n)$  be any sequence: We define:  $(t_n) + (t'_n) = (t_n + t'_n)$  and  $a(t_n) = (at_n)$  where  $(t'_n)$  is another sequence and  $a$  any number. We thus give to the set of sequences a structure, in mathematics, called vector space. This will be useful later.

Mathematical considerations : We are going to develop some of them which can be useful during the assemblies with the forms for example with what the Anglo-Saxons call "Radionics".

Let us therefore consider the sequences  $(V_n)$  and  $(W_n)$  such that  $V_n = V_{n-1} + V_{n-2}$  and  $W_n = W_{n-1} + W_{n-2}$ . The values  $V_1, V_2$ , and  $W_1, W_2$  are not fixed.

If  $a$  and  $p$  are numbers, then  $a(V_n) + p(W_n) = (aV_n + pW_n)$  is a sequence of the same type, i.e. if  $Z_n = aV_n + pW_n$  the sequence  $(Z_n)$  has the property:  $Z_n = Z_{n-1} + Z_{n-2}$ . The proof is left to the reader.

Thus sequences such as  $(W_n)$  form a vector space. A vector space has certain dimensions. These are the ones we are going to look for. This can be useful for the study of forms.

We start again from  $(U_n)$  such that  $U_n = U_{n-1} + U_{n-2}$ . It can be shown that all sequences such that  $(U_n)$  can be written as a linear combination of two sequences  $(V_n)$  and  $(V'_n)$ .

Proof : Consider 2 non-proportional solutions  $V = (V_n)$  and  $V'' = (V''_n)$  such that:  $V'_n = V'_{n-1} + V'_{n-2}$

$$\text{and } V''_n = V''_{n-1} + V''_{n-2}$$

Let us show that any sequence  $V = (V_n)$  such that  $V_n = V_{n-1} + V_{n-2}$  can be written  $V = C_1 V' + C_2 V''$  where  $C_1$  and  $C_2$  are two numbers.

First show that if  $V$  and  $V''$  of the type above are not proportional then

— Suppose  $\frac{V'_i V'_2}{V'_2 V'_1} = \frac{V''_i V''_2}{V''_2 V''_1}$  then  $\frac{V'_i V'_2}{V'_2 V'_1} = \frac{V''_i V''_2}{V''_2 V''_1} + \frac{V'_2 V'_1 + V'_2 V'_3}{V'_2 V'_1 + V'_2 V'_3}$  etc... so  $V$  and  $V''$  are

$V'_i V'_2$  proportional. Hence if they are not proportional then:

$$\frac{V'_i V'_2}{V'_2 V'_1} \neq \frac{V''_i V''_2}{V''_2 V''_1}$$

Consider  $V$  such that  $V_n = V_{n-1} + V_{n-2}$ . It is perfectly determined if we know  $V_1$  and  $V_2$ .

We are looking for two constants  $C_1$  and  $C_2$  such that  $V_1 = C_1 V'_1 + C_2 V''_1$

$$V_2 = C_1 V'_2 + C_2 V''_2$$

$C_1$  and  $C_2$  exist and are unique because  $V$  and  $V''$  are not proportional, i.e. the

determining:  $\frac{V'_1 V''_1}{V'_2 V''_2} \neq 0$

$$\text{But } C_1 = \frac{V_1 V''_2 - V_2 V''_1}{V'_1 V''_2 - V'_2 V''_1} \quad \text{and } V = C_1 V' + C_2 V''$$

Hence it suffices to find 2 solutions.

Thus the vector space of sequences  $V = (V_n)$  such that  $V_n = V_{n-1} + V_{n-2}$  has two dimensions over the field of real numbers.

Let us seek among the basis vectors those of the form of a geometric progression of 1<sup>st</sup> term 1 and ratio  $q$ ; i.e.  $1, q, q^2, \dots$

It is necessary that  $q^n = q^{n-1} + q^{n-2}$  from where  $q^2 = q + 1$

$$\alpha = \frac{1 + \sqrt{5}}{2}; \beta = \frac{1 - \sqrt{5}}{2}$$

$\alpha \beta = -1$ ; here  $V = (V_n) = (a^n)$

$$V = (V''_n) + (p^n)$$

$$V'_1 = 1 \quad V''_1 = 1 \quad 11$$

so

whence the sequence  $(C_1 + C_2, C_1 \alpha + C_2 \beta, C_1 \alpha^2 + C_2 \beta^2, \dots)$

Now certain values of  $C_1$  and  $C_2$  will give the Fibonacci sequence.

$$\begin{aligned} C_1 + C_2 &= u_1 = 1 \\ C_1 \alpha + C_2 \beta &= u_2 = 1 \end{aligned} \quad \text{i.e. } \begin{aligned} C_1 + C_2 &= 1 \\ C_1 \alpha + C_2 \beta &= 1 \end{aligned}$$

hence  $U_n = C a^{n-1} + C_2 P^{n-1}$   $\frac{1 + A/5 \sqrt{5} p}{2}$  To 2 ) (Binet formula)

Consequence :

$$a^2 = a + 1$$

$$a^3 = a(a + 1) = a + 1 + a = 2a + 1$$

$$a^4 = a(2a + 1) = 2a + 2 + a = 3a + 2$$

Suppose  $a^k = U_k a + U_{k-1}$  where  $(u_0)$  is the Fibonacci sequence and  $a^{k+1} = U_{k+1} a + U_k$

For  $k = 2, 3$  this formula is true

$$a^k + a^{k+1} = (u_k + U_{k+1})a + (u_{k+1} + u_0)$$

$$a^{k+2} = U_{k+2} a + U_{k+1}$$

what is demonstrated.

Complement :

We can take  $V'_1 = 1, V'_2 = 0, \dots, V' = (1, 0, 1, 1, 2, \dots)$

$$V = C_1 V' + C_2 V'' = (V_1, v_2, v_3, v_4, \dots)$$

$$= (C_1, C_2, C_1 + C_2, C_1 + 2C_2, 2C_1 + 3C_2, \dots) \text{ where } V'_n = V'_{n-1} + V'_{n-2}$$

$C_1 = V_1$   
 $C_1$  and  $C_2$  are uniquely determined.

If  $V' = (1, 0, 1, \dots)$  and  $V'' = (0, 1, 1, \dots)$ , the sequence of Fibonacci is  $V = V' + V''$

Fibonacci sequence and geometry

Consider a straight line which bears the points A, B, C<sub>1</sub>, C<sub>2</sub> such that  $\frac{AB}{BC_1} = \frac{BC_1}{C_1 C_2}$  Let's share AB that -----

so that the larger of the 2 parts is the proportional mean of the smaller and of the entire segment.

<sup>11</sup> AB denotes an oriented segment

—I -----1 -----1 -----1 -----

$G^2$  AC] B Ce q U | j onne . - =  $\frac{1}{p}$  it's up to

say  $x^2 = 1 - x \Rightarrow$  positive root  $x = \frac{1 + \sqrt{5}}{2} = (p.$

Which expresses  $\frac{AB}{C_1B} = \frac{C_1B}{AB}$

This division is called: division into mean and extreme reason.

If we consider the negative root, the point C<sub>2</sub> which corresponds to it is outside the segment

AB (we say that C<sub>2</sub> shares AB externally) and:  $\frac{C_2B}{AB} = \frac{AB}{C_2B}$ ; if we set C<sub>2</sub>B = y, we

y then  $\frac{1}{y} = 1 + \sqrt{5} \Rightarrow y = \frac{1}{1 + \sqrt{5}}$

$\frac{C_2C_1}{C_2A} = \frac{C_2B}{C_1B} = \frac{1}{p}$  (p<sup>2</sup> - 1 = G) so  $= \frac{C_2C_1}{C_2B}$

Complement :

AB = 1 and AE = z. Place on EB, D such that

ED = EA = z and on AB, C<sub>1</sub> such that BD = BC<sub>1</sub>.

We draw  $\frac{y}{z} = \frac{BD}{BC_1} = \frac{1}{p}$ . We thus place on

AB the point C<sub>1</sub>; we place C<sub>2</sub> because

AC<sub>2</sub> = BC<sub>1</sub>. The points C<sub>1</sub> and C<sub>2</sub> are thus constructed. Let AB = 1 and the point C at the location of C<sub>1</sub> therefore CB = x. Let I be the midpoint of CB. Let us draw the semicircle of radius AI and the

AI = IN =  $\frac{1}{2}(1-x)$  and from CI<sup>2</sup> + CN<sup>2</sup> = IN<sup>2</sup> = AI<sup>2</sup> and x<sup>2</sup> = 1 - x we draw CN =

CN=CB.

We immediately draw a square inscribed in the semi-circle whose 3 vertices are N, C, B.

Exercise :

On colore, dans cette figure le carré en bleu profond. La figure émet le  $Bu_M$  à la verticale.

Etudes de polygones :

a) le décagone régulier convexe :

Let  $C$  be the side and  $R$  the radius of the circumscribed circle.

$$C = 2R \sin 18^\circ$$

$$\sin 36^\circ = 2 \sin 18^\circ \cos 18^\circ$$

$$\cos 36^\circ = 1 - 2 \sin^2 18^\circ$$

$$\sin 72^\circ = 4 \sin 18^\circ \cos 18^\circ (1 - 2 \sin^2 18^\circ)$$

$$\text{Or } \sin 72^\circ = \cos 18^\circ$$

$$\text{so } 1 = 4 \sin 18^\circ (1 - 2 \sin^2 18^\circ)$$

Thus  $\sin 18^\circ$  is a positive root of the equation  $8y^3 - 4y + 1 = 0$ , so an obvious solution is  $y_i = y$

which is not  $\sin 18^\circ$ .

So we come back to the equation:  $4y^2 + 2y - 1 = 0$

$$\text{solutions } y = \frac{-1 \pm \sqrt{5}}{4}$$

$$\text{donc } \sin 18^\circ = \frac{2/L - 1}{4} = \frac{L}{2(p)}$$

$$\cos 36^\circ = 1 - 2 \sin^2 18^\circ = 1 - \frac{1}{2} \left( \frac{2/L - 1}{2} \right)^2 = \frac{1}{2} \left( \frac{2/L + 1}{2} \right)^2$$

$$\text{Ainsi } C = 2R \sin 18^\circ = \frac{R}{2}$$

b) Length of the side of the stellated decagon (the vertices of the convex decagon are connected 3 by 3)

$$C' = 2R \sin 54^\circ = 2R \cos 36^\circ = R(p). \text{ Thus: } C' = R(p)$$

c) The star pentagon

Points A, B, C, D, E, F are arranged as in the figure:

$$\angle AFD = 108^\circ \quad \angle ADF = 36^\circ \quad \frac{AD \sin 108^\circ \sin 72^\circ}{\sin 36^\circ} = \frac{1 + \sqrt{5}}{4} \cdot AD = 2 \cos 36^\circ = 2$$

Or  $AF = AC$  d'où  $\frac{AD}{AF} = \frac{AD}{AC} = \phi$  et  
C divise AD en moyenne et extrême raison.

Mais  $\frac{AC}{CD} = \phi$  ; vu que  $AB = CD$

on obtient  $\frac{AC}{AB} = \frac{AB}{BC} = \phi$

Ainsi :  $AB = \phi \times BC$

$AC = \phi \times AB$

$AD = \phi \times AC$

$$\frac{AD}{AF} = \phi \text{ car } \frac{AD}{AF} = \frac{AD}{AC} = \phi \quad \frac{AD}{AF} = 2 \cos 36^\circ = 1$$

The width of the star pentagon is:  $2R \sin 72^\circ = 2R \cos 18^\circ$

Note : In all form work angles are measured in degrees; the other units are much less interesting.

It will happen that to numbers we will be able to associate the degree as a unit. This will bring up properties that are not obvious.

Consequences : We can consider (p thus where  $AX = 1$  and  $XB = (p$

We find  $AB = (p^2$  that is to say  $(p^2 = (p + 1$  so  $\phi$  is the positive root of  $x^2 - x - 1 = 0$ . Here we have used an A B point X. This goes serve to extend this construction, which will give the Radiant number.

Exercise : These plots respond to | K Sh Ph with reversed Sh >

Egyptian harmonic tracings (after M. Ghyka)

We give ourselves the rectangle ADEF and the points B and C as in the figure such that  $AB = DC = AD = 1$ ,  $AF = DE = (p$ . I and J are the respective midpoints of AD and EF. K is the intersection of IJ with BC We draw DF and BE.

2) Show that we detect the reversed schin at K - naturally, we must not draw it on the figure -.

Answer :

1) from  $(p^2 = (p+1)^2 - 1)$  we get  $\frac{1}{p} = \frac{1}{p+1} + \frac{1}{p(p+1)}$  so  $\frac{1}{p} = \frac{1}{p+1} + \frac{1}{p(p+1)}$  so the 2 triangles DEF and BFE are

similar which here involves a rotation of  $90^\circ$ , so the corresponding sides are perpendicular.

Problem :

We give ourselves the same figure but we construct the path  $ACC'C''...$  such that  $CC'$  is perpendicular to  $AC$ ,  $C'C''$  is perpendicular to  $CC'$  etc...

In the rotation of center G and of angle  $90^\circ$ ,  
followed by the homothety of center G and ratio

$\sim$  points A, B, F, E, C, D are transformed

respectively in CB'B F C'E therefore AC

combined with the homothety of ratio and center  $G$  and so on. The segments  $c^{\wedge}c^{\wedge}n^{\wedge}\dot{U}$

tend to  $G$ .

Let's drill a hole in K and holes in the middle of BC' then of B'C" etc... We can draw a spiral - dotted in the figure - passing through these holes which ends in G where we make a hole.

- 1) Check that at K we find the right schin.
- 2) Check that in G one detects the right schin above and the 4 components of the vital field.

- 3) We remove all the holes except the one in K. Check that we still detect the right schin above.

### *HAS. . Complement to the golden ratio*

Spiral obtained from the golden number  $\phi$ : it is necessary to drill holes in certain places so that the interesting properties appear.

Assembly left as exercise

### Transposition in plane of the sphere: CHAUMERY-BELIZAL

(production by J. de la Foÿe)

By moving a cylinder over the disc, the emission at the surface is detected in the form of a vertical emission or detected at 180°. We find the spirals, geometric loci of “colors”. A needle in the center emits in the extension of the  $V^+M$ , the colors of the aura figured on the exterior of the equator. A needle focused on the R- $V^+M$  HOLE directed towards the center will emit the undifferentiated R along the  $V^+M$  AXIS in 180°.

#### *B. Radiant Number*

We took a point X on a segment AB, now let's place two X and Y in two. This is what Gérard Cordonnier did in 1924 when he was in Higher Mathematics class at the Lycée Charlemagne in Paris. He was to enter the Polytechnic school 2 years later.

At the Ecole Polytechnique he carried out very promising experiments on clairvoyance and mathematics and when he left he continued research on the Radiant Number  $\backslash/$  - so he wrote -, then on a good number of stigmatized people including Thérèse Neuman, Marthe Robin, Padre Pio etc...

He directed the second major study on the Shroud of Turin in 1932. It should be noted that as a reward for his quality as organizer of this major congress and his strong remarks

judicious, he was offered 1 cm<sup>2</sup> of the Argenteuil Tunic. This piece of fabric was placed by him between two blades with parallel faces. It issued remarkable eifs. It was used 4 times by Gérard Cordonnier and placed near dying people who were saved in a short time.

His experiments on clairvoyance during sleep, where he found 2 to 3 solutions to problems posed by certain professors at the Ecole Polytechnique, including Gaston Julia, showed how efficient the brain can be during sleep. He had the chance, on waking, to remember the complete solutions, which greatly astonished his comrades who were quickly convinced that no trickery slipped into these experiments.

So let's divide a segment AB into 3 segments for points x and y.

We get  $1/J^5 = 1 + 1/J + V/J^2$  and

$\sqrt[4]{f} = \sqrt[4]{1 + 1/J^2}$  which leads to the unique relation  $1/J^3 = 1 + \sqrt[4]{f}$  i.e.

$x^3 - x - 1 = 0$  so  $1/J$  is the positive real root .

G. Cordonnier tried to generalize again by using no longer 2 points

but 3 to divide the segment AB into 4 parts, i.e. the points X, Y, Z and again X, Y, Z, T, ... to generalize even more. But from 3 points, X, Y, Z the process no longer allows placing the additional segments on the same progression as that of the primary segments. Thus the progression with the segments for obtaining the number Radiant  $1/J$  presents the maximum of arithmetic properties on a geometric progression.

Note the formula  $(1/J - 1) \cdot J(\sqrt[4]{f} + 1) = 1$  which expresses that 3 factors in arithmetic progression of ratio 1 have a geometric progression equal to 1.

For the Golden ratio the analogous formula was with 2 terms  $p((p - 1) = 1$ .

Twice 17 years after his first discovery remained in germ, Gérard Cordonnier is invited to make a presentation at the International Congress of Symbolism at UNESCO. He exposes there for the first time in public the extraordinary properties of the number Radiant  $1/J$ .

Listeners want a book. G. Cordonnier sets to work, but, on the point of completing a drafting for the use of engineers and architects, realizes that the understanding of the Radiant Number must be offered to the general public. It resumes its entire presentation by deferring in appendix all the mathematical developments to leave in the text only an initiation in images within the reach of all.

In 1958, he gave lectures comprising around a hundred projections, including many views of monuments, showing that architects had often foreseen the harmony of the Radiant Number  $\sqrt[4]{2}$  without knowing the theoretical justification for it.

The work - which was to be called - "Beyond the Golden Number... the Radiant Number" was to analyze using layers to be superimposed on the original unaltered photographs the progression, or often the various progressions  $\sqrt[4]{2}$ , used, very close to the number Radiant  $\sqrt[4]{2}$ .

This indeed has the approximate value  $\sqrt[4]{2} = 1.325...$  and its inverse  $Y = \sqrt[4]{2}^{-1} = 0.755$ .

The radiant geometric progression, increasing or decreasing, is therefore very close to the  $\frac{4}{3}$  progression or (1.333... and 0.75...).

This happy coincidence recalls that of the tempered scale - twelfth root of 2 - with certain simple ratios.

Note the approximate values of  $\sqrt[4]{2}$ : and Moreover, a sequence analogous to that of Fibonacci - we have called it the Cordonnier sequence - quickly and indefinitely approaches a geometric progression  $\sqrt[4]{2}$ . We write 1, 1, 1... and each term is obtained by adding the two preceding the last.

1 1 1 2 2 3 4 5 7 9 12 16 21 28 37 49 65 85 114 151 200 265 351 465 616 816 1081 1432 1897 2313...

By dividing by 2 the numbers after 200, we obtain the approximate values of the successive powers of  $\sqrt[4]{2}$ . Before 210, up to 45, we also obtain sufficient approximations of the negative powers.

Note also the value  $0 = \sqrt[4]{2}^{-1} = 1.151...$  and  $\sqrt[4]{2}^{-1} = 1.10$  and  $(1,1)^3 = 1.331$ .

We can draw for example 2 polygonal spirals, what G. Cordonnier named  $\sqrt[4]{2} \cdot 60^\circ$   $\sqrt[4]{2} \cdot 50^\circ$ .  
Exercise : Check that the right schin is detected in the center of the spirals.

Let's go back to the continuation of G. Cordonnier

11 1223457912...and let's write it again, shifting one place  
1 1 1 223457 9 ...

Let's make the ratios according to the numbers placed on the same vertical.

5.4 5 79 12  
1121 z3 457 9 ■■■

We obtain a new sequence which tends to  $\hat{A}/\psi$ .

Another  $0.40^\circ$  spiral derives from the study of the family of tetrahedra  $C_V D$  whose edges are in geometric progression. A boundary tetrahedron  $A / AXYB$  aligned defined the progression  $\psi$ . One of the tetrahedra has 3 edges

+ • + ii -A // A 1 B

You have to bend at  $90^\circ$  in BC.

G. Cordonnier had also discovered a triangle with interesting properties: he called it the “radiant triangle”. Its sides are 1,

If  $AC = 1$ ,  $AB = 1/J$ ,  $BC = \psi/A/J$ , the angles are a few minutes of arc from those indicated in the figure.

We can take these angles to draw the triangle, the approximation is quite correct. This triangle does not meet  $|K Sh Ph >$ .

Here is one of the tetrahedra of the sequence of tetrahedra which has 3

Notes :

- 1)  $\frac{1}{\sqrt{2}}$ , the Radiant number does not invert the polarized body of the tree trunk.
- 2) In the reports drawn from the continuation of G. Cordonnier, one finds: and two terms which one

finds in the sequence  $1, 1, r; 1, T; T; T; z; OH; TS. \dots$  sequence tending to  $\frac{1}{\sqrt{2}}$ .

We see that the sequence of G. Cordonnier can be defined as follows:

$$u_1 = u_2 = u_3 = 1$$

$$u_4 = u_2 + u_1$$

$$u_n = u_{n-2} + u_{n-3}$$

The sequences  $(v_n)$  such that  $v_n = v_{n-2} + v_{n-3}$  form a vector space.

If  $(v')$  and  $(v'')$  are two such sequences and if  $\frac{v'_1}{v''_1} = \frac{v'_2}{v''_2} = \frac{v'_3}{v''_3} = \dots$  then  $(v')$  and  $(v'')$  are proportional:

Demonstration:

$$\frac{v'_1}{v''_1} = \frac{v'_2}{v''_2} = \frac{v'_3}{v''_3} = \dots = \frac{v'_n}{v''_n} = \frac{v'_1 + v'_2 + v'_3 + \dots + v'_n}{v''_1 + v''_2 + v''_3 + \dots + v''_n} = \frac{v'_n}{v''_n} = \dots$$

proportional it suffices that: or or

A sequence  $(v)$  such that  $v_n = v_{n-2} + v_{n-3}$  is perfectly determined if we know  $v_1, v_2, v_3$ .

Let  $v = (1, 0, 0, 1, 0, 1, \dots)$   
 $v' = (0, 1, 0, 1, 1, 1, 2, \dots)$  " 3 such sequences and  $t = (t_1, t_2, t_3, t_j, \dots)$  where  $t_n = t_{n-2} + t_{n-3}$   
 $v'' = (0, 0, 1, 0, 1, 1, 1, 2, \dots)$ .

$$\text{then } t = c_1 v + c_2 v' + c_3 v''$$

with  $c_1 = t_1, c_2 = t_2, c_3 = t_3$  and  $t = (c_1, c_2, c_3, c_1 + c_2, c_2 + c_3, \dots)$

The dimension of the vector space of sequences  $(z_n)$  such that  $z_n = z_{n-2} + z_{n-3}$  is therefore 3.

Exercise : We are given the radiant triangle and a circle of radius  $\frac{1}{\sqrt{2}}$ . We make the lines as in the figure below: We drill in the center of the circle. Show that we determine the right schin on the axis of the circle, above the plane of the figure and the 4 components of the vital field. Check that the NF is imposed by the figure.

Notes :

Give us three numbers  $a, b, c$  positive integers. Consider the sequence  $u_1 = a, u_2 = b, u_3 =$

$$c, u_4 = u_2 + u_1, u_n = u_{n-2} + u_{n-3}$$

Let's build the sequence I So U/.  
W17 A-I T

- It is possible to use vectors from the vector space of these sequences, which as we have seen, is of dimension 3. With a vector we can generate eifs.

The scientific world to which I belong  
is largely  
as corrupt as the political world <sup>1</sup>

Haroun Tazieff

<sup>1</sup> Quoted on December 9, 1994 on “France Culture”.

### C. Transmitter plate of Jean de la Fo  e

The radii and diameters plotted illustrate the physical field. The circular plate must have a hole in its center right through.

With a needle of length  $2R$ , the differentiated spectrum is detected at  $V^+M$ .

With a needle of length  $R$ , the undifferentiated spectrum is detected at  $V^+M$ .

### D. Square transmitter tray

It is interesting to produce an undifferentiated and differentiated spectra emitting plate which does not start from the physical field.

This plate is a square, drilled in the center to avoid any RW cH.

We start from 4 equilateral triangles inscribed in a square.

The differentiated spectrum will be distributed on the sides of the square, the output is still at  $V + M$ - We find the polarities as soon as we have drawn homothetically the square of the plate, in a homothety of ratio  $\sqrt{2}$  and center the center of the plate, another square that will support the undifferentiated spectrum.

The colors are no longer at equal distances.

Notes :

- the nature of the top material is important, wood is satisfactory. On the other hand, square trays were made of agglomerated stone; the eifs that come out change over time.
- The square wooden top is very stable, more stable than a circular top in the same wood.
- Some segments need to be engraved but not all.

Square emitter

T

Jean

Richer cites in a rapid study a plate with stamped reliefs found at Delphi in two fragments, one part between the Athenian treasury and the wall of Téménos, the other against the wall of Téménos and of which it is thought that it was a part of the decoration of the crowning of a small votive shrine. He then assumes a complete reconstruction of the crowning of the building and perhaps even of the shape of its roof with a probably octagonal summit.

<sup>2</sup> Jean Richer, Delphi, Delos and Cumae, Edit. Julliard, Paris (1970)

The reconstitution of this roof according to Richer is reproduced opposite: the zodiacal signs are shown around the drawing: centaur, goat, satyr, ophion, sphinx, gorgon, two lions, crab, horseman, boar, ram, bull.

The plate found corresponds to the signs: two lions, crab, horseman.

We can be inspired by this ceiling which existed or not differentiated and even the undifferentiated, which is square to the instead of being circular. It is necessary to pierce the center right through to eliminate the level of equivalence R WCH. It is necessary to draw the diagonals, moreover it is necessary to draw four equilateral triangles arranged as in the figure. Their intersection is an octagon. It is necessary to draw the line at  $60^\circ$  to the right of the line  $V^+E$ ,  $V^+M$ , and the line at  $40^\circ$  to the left of this line. By drawing the homothetic square of the first square (the homothety having as its ratio  $\times/2$ ) the differentiated spectrum is generated on the circumference of the first square, the colors being on radii which are 15 in  $15^\circ$  and the undifferentiated spectrum being on the circumference of the second square. We have the polarity + on the line  $V^+E$ ,  $V^+M$  everywhere except inside the small square and the polarity - symmetrical with respect to this line. The figure in the center is a not regular convex octagon.

### *E. A few additions to the forms*

It may happen that forms are not testable, we will call them untestable forms. This is the conclusion that we arrive at when we have tried the detection devices, that we are looking for whether there is no overlap, equimsey<sup>3</sup>, etc...

So we can't know anything about these forms.

Moreover, as has been pointed out several times in the preceding chapters, the domain of forms must accustom us to leaving aside the a priori of rational thought. We can therefore find forms that are both testable and untestable. These are characteristics that assembled on the same form, make the form completely escapes us in the approach. The shape can be localized or partially localized.

<sup>3</sup> Concepts that will be considered in the 2nd year course .

Let's also look at the so-called " moment-dependent " forms . We noticed while working on certain shapes that their eifs and states were not the same if these shapes were reproduced, apparently identical, in the same places but at different times.

Does this mean that they depended on the moment? Nope ! The word moment was chosen knowing that it depends on the context, the turn of the sentences, the atmospheres in which they are inserted. The meaning of the words is revealed in the sentence, the moment, but they impose the meaning of the sentence which means that we do not have a system with two positions in time but the meaning of the word which generally comes from the past finds to be rethought, reinvested to be born in the sentence to which it gives meaning. We are in a primer-progenitor system <sup>4</sup> .

Let's take the word moment, in all possible situations, with all the sensations that we have while thinking this word; projecting onto this multitude the concept of the moment, we have what is called the Aureolar <sup>5</sup> of the moment. We will also name "Moment" the halo of the moment. It is in this sense that we will use the word moment in the expression "Forms which depend on the moment".

The living is always represented by forms that depend on the moment. Some forms like the Ark of the Covenant are time dependent forms.

The First Temple in Jerusalem was such that some of its dimensions and unit of measurement were thought to suit the times. It may even be that the unit of measurement was linked to a direction, itself found according to the moment; this is why if we redo the same shape by thinking it, for the 3 dimensions of space with the same unit for each one, for example an Egyptian cubit, it is not operative.

A form that depends on the moment can be preserved but at certain times it cannot be reconstructed. The notion "same as" may depend on the moment.

In alchemy you have to take into account the moment; thus many grimoires are useless if they describe time-related operations. They have only a historical value and by one way - this other way belonging to Alphysics" - we will be able to know the moment when the grimoire presented operative phases.

About the thoughts of some initiates, these thoughts could not be taken up by other people at any time; as forms, these thoughts depended on the moment. The disciple is the one who was

<sup>4</sup> See the book by Jacques Ravatin and Anne-Marie Branca: "Theory of Forms and Fields of Coherence" (to be published)

<sup>5</sup> ditto

the Master gives him the power to resume the teaching, at another time perhaps, but keeping everything "The substantive marrow" as Montaigne would have said.

Is a form that is not time-dependent a degeneration of a form that is time-dependent even though feeling unconstrained by time gives a feeling of greater freedom? One must be wary, in this domain of forms, of what one thinks one gains; one can, by gaining too great an adaptation, as in rational science such is the habit, lose a fundamental essence; in a sense a moment-dependent form is more an emergence than a form which one might call free - This does not mean that a free form is not in certain cases as delocalized as a moment-dependent form.

Examples of shapes that depend on momentum :

Consider a square of side length  $c$  and a circle of diameter  $d = c/2$  having the same center as that of the square. There are 8 points of intersection between the square and the circle. The fact of drawing these two figures in this way means that they are not located at the same level if we think of them separately, that is to say when they are drawn one on top of the other, if we think of the figure total as the meeting of the circle and the square. If we don't think of the definitive figure as composed of two figures, it turns out that the form is dependent on the moment. It responds neither to R WcH nor to any K Sh Ph, but the eifs after a certain time will no longer be the same if we make ourselves the identical form and if we use this form to rebalance from a witness , this role will disappear little by little to reappear perhaps a long time later and to disappear again. It is not a form with variable eifs. If we want to fix this shape so that it keeps the eifs, states whatever the moment when it was drawn, we must drill one of the 8 holes (this will not be the same depending on the moment) and put a protrusion at the diametrically opposite point (what we will call an anti-hole). After this operation, this form will no longer depend on the moment. Such a form can emit at high T.C.s.

Caption : Two other shapes inspired by the previous one. The holes and anti-holes are marked but they must be replaced because the reproduction process does not freeze the fixing necessary if we want these shapes not to depend on the moment.

## **The “Kéroub” (or Cheroub) prize**

by Anne-Marie BRANCA

This first year ends with this booklet. Also to conclude we are going to present this study which apparently has a role of digression in relation to the subjects treated.

But it is necessary to place the researchers whose work we will gradually approach.

Thus in a Pantheon, are:

Victor Schauburger, J. Keely, N. Tesla, E. Hendershott, Th. Moray, L. and MT Sprink, H. Morichini, L. Rota, L. Boutard, G. Lakhovsky, S. Brignand, F. Dufourg, Le Prince Skariatine, W. Reich, A. Prioré, A. Béchamp, D. Ghadiali, F. Crombette, G. Claude and J. Coutelen, G. Bergé, H. Mayer, A. Schmidt, T. Brown, Laithwait, Abbé Fortin and many others, we haven't found them all.

They still deserved a prize, those who were voluntarily forgotten.

This is the Cheroub Prize.

Chéroub: word made by us and which we unveiled for the first time at the Carnac congress in 1996 <sup>6</sup>.

Chéroub comes from 2 words: FORGOTTEN CHERcheur.

The researchers quoted above would have each deserved several Nobel Prizes but their names were not even retained even admitting that they were presented. Their names are not on any stele because they had no right of expression, even of existence.

The plural of Cheroub is naturally Cheroubim - We will still write Kéroub and Kéroubim -

Thus these researchers will receive the Kéroub distinction.

A ceremony is organized by the EUREK'ALL Company for the awarding of the Prize <sup>7</sup>.

<sup>6</sup> Congress held from June 29 to July 7, 1996, the theme of which was... “The Study of Forms”. It was organized by Anne-Marie Branca from the EUREK'ALL Company and Bernard MENGUY from the ARKOLOGIE Association.

<sup>7</sup> As for the RBB, it is also awarded a Prize: the Lebon Prize (Lebon: Nobel backwards). This Lebon Prize was imagined by Frédéric Ravatin, when he was a student engineer around 1979. This prize is reserved for a kind of individuals who are characterized as follows: sure of their abilities, eager for honor, with a cluttered brain of knowledge - "legged libraries" -, competent in certain fields, exceeding in their assessments the field or fields of knowledge, making "hasty" judgments on individuals - they work out absolute scales of classification of human beings, established according to gender criteria: the school from which the individual leaves, the ranks of entry and exit of the school, alertness, turn of mind. It's the RBB that reinstalls RBB! We have to admit that we hear far too many “researchers” claiming to be researchers, “scientists” claiming to be scientists. In fact, they are scientists, researchers

in laboratories, universities. They allow themselves in the name of their titles, even more Science - it would still be necessary that these cranks manage to realize that Science does not belong to them, that they do not represent it, that they cannot invoke it As they wish. Science, as an entity, is not on the scale of a man - to speak of what they do not know, which is contrary to all scientific ethics; and moreover they allow themselves to approach domains which are not in the rational C. de C. and to take advantage of it to ridicule and reject them. There are very few real researchers, who have the soul, and very few scientists worthy of bearing this title. We are at a time when titles and denominations are distributed haphazardly, deformed, a handyman who repairs his radio claims to be an electronics technician, people with a bad cold present themselves as having the flu. - They treat themselves like having the flu, which makes the drug manufacturers happy. This attitude is an index of mediocrity in a society increasingly subject to a degeneration which manifests itself in particular in verbal formulation. - It is for all this that it was more than necessary to create the Lebon Prize.

While the Nobel Prize is discerned only fairly sparingly, the Lebon Prize will be awarded quite frequently, the people worthy of receiving it being quite numerous. It may even happen that a Nobel is Lebon! The reverse is, it seems, much rarer!

## Introduction to the Study of Forms and Coherence fields

2nd year <sup>course</sup>

“The form can be fixed, frozen;  
it expresses the dynamism of the human spirit. »

Anne Marie Branca

**Cross of Saint Maur**

which is located in the abbey of Saint-Maur, on the banks of the Loire, near Angers

## *Introduction to part <sup>2</sup>*

We saw in the <sup>1st</sup> part of this course - <sup>1st</sup> level of the booklets - an approach to the study of forms. We hadn't insisted too much on the concept of form. We will now dwell on them at greater length while introducing a new form of thought in which these concepts will evolve.

Advice : The reader of this 2nd <sup>lesson</sup> must read the entire text in order to become gradually immersed in this new form of thought.

Some will be able to claim that it is not a question of a form of thought but of an attitude of singularization of a group of researchers compared to the usual researchers. They are seriously mistaken: the concepts that are going to be presented little by little and their arrangements are not at all insertable in the rational, usual thought that we will call Rational or usual Fields of Coherence <sup>1</sup>.

## *Attitude and Intent*

It is necessary that the reader of this course lets himself be impregnated little by little by the concepts which will be put in place during the development of the 2nd <sup>level</sup> of this course.

We find ourselves as we should be.

One must have an attitude to conduct this unorthodox research; one must always keep oneself "impeccable" as C. Castaneda wrote. It is the attitude of the "impeccable warrior" by its rigidity, its vigilance, its open-mindedness, its possibilities of adaptation to the multiple situations which are found in the multiple representations, the attitude is not fixed but must be as it should be in the moment considered. We will see that the moment takes on here not a particular meaning, but that it is under its true meaning, such as it should be conceived, felt.

We must realize that we are a form, a system of forms that depend on the moment. The attitude does not impose the moment, nor does it not impose itself in the moment, they will be linked according to a process which does not take place in rational thought. <sup>1 2</sup>

<sup>1</sup> C. of C. for Field of Coherence.

<sup>2</sup> We have seen in booklet 9 of the <sup>st</sup> level of this course the meaning to be given to this word. This word moment even in a usual sense is not perfectly determined. It is already in most cases different from the time interval.

Some could say, and in particular the rationalists, that these concepts are useless, or outdated according to the consecrated and often disparaging expression; Kant and Descartes did not quite see the relationship between man and the world as we now see it in philosophy, which seems to have yielded a little too much to the scientific description of the world.

We are taking up concepts from the Ancients because we noticed that some of these concepts had been misunderstood, deformed; they could not be assimilated by ordinary thought. This usual thought is not the only one possible; we are working to put another one in place; a new language is necessary, that is, the creation of terms and the assembly of these terms.

Rationalists <sup>3</sup> will find this construction obsolete since for them there is only one approach to understanding: that of rational thought. And yet the ancients did not think as modern man thinks. An important consequence of this remark is that the world appeared differently. Thus can be justified this thought of Christ: "There are many dwellings in my Father's house".

When we talk about attitude and moment, we think that they are linked. Their connection, which will be presented in the following fascicles, is due to a tension which has occurred at the cerebral level in the sensation of the two concepts, the need to create a fusion between them; then an atmosphere arises of which one is unaware; there is no longer any goal which would be to set up something else, simply an atmosphere; when the observer by his thought bathes in this atmosphere, he fertilizes himself and the concept springs up. As they say: the new concept is not going to be a goal, but it is the atmosphere itself. And if we wanted to justify this birth, that of the concept from the atmosphere, we would have to immerse ourselves in this atmosphere that will bathe all this work, to say to ourselves that the expression "traveling through the atmosphere to generate the concept" does not is perhaps not quite exact but that this concept and the atmosphere are already before existing in consciousness, and this in the sense that will allow us to half-open the intention: the intention becomes the implementation of the voltage(s).

And in this second level of the course, this situation will be reproduced in the arrangement of the concepts. There will be no before the comparison of concepts, nor after this comparison; from their existence, all the consequences are. We are then faced with a kind

<sup>3</sup> We prefer to speak of stupid and limited rationalists (RBB); they are more and more numerous among the rationalists as a whole.

of "vertical" thought compared to the usual thought which is expressed according to the scale of time and which can be envisaged as a "horizontal" thought, horizontal because there is flow of time.

Tensions may present themselves differently; we will say that they have 'faces'. These faces will be considered later.

This "vertical" thought is not with the passage of time. We should not consider two times, a "horizontal", that of physicists, and another "vertical".

Intention manifests itself in existence without landmarks.

So attitude and moment are linked by a tension face. The attitude cannot be precisely described; it will be said to be barely identifiable or not identifiable at all. We can talk about it, as we would in the rational world of a noumenon.

Similarly, the moment is not identifiable; it is not a time interval. In the moment are intervals of time nested or not, but if we fix an origin of time for the moment, we will not be able to define the limits exactly, whether these intervals are open or closed in the mathematical sense of the terms. The intervals will seem to leak out and their definition fade away. The concept of interval becomes unstable. The noumenon is also not identifiable, not expressible by rational thought <sup>4</sup>.

One can, on the other hand, envisage a passage from the phenomenon to the noumenon, which will call for a way and one will write: . Naturally this way has existence only by the concepts of departure and arrival. By permuting them we would have the opposite way which we will write way'l.

The concepts that we will put in place little by little and the paths between these concepts will be transported to other concepts like schemas. Multiple tracks can be placed according to geometric figures, such as starry pentagons or other flat shapes. Such figures and the ways will constitute new entities which will be able to associate. Ways and concepts can be exchanged in the schemes.

<sup>4</sup> In Kant's philosophy, the noumenon is the "thing in itself", such as it exists, independently of any being capable of knowing it or feeling it. The noumenon is opposed to the phenomenon which is the thing as it appears to our mind; experience only lets us know the phenomenon, and the noumenon escapes all experimental knowledge; the fundamental problem of philosophy is, according to Kant, precisely whether the human mind can, by reason, reach the noumenon [i]. Here too, phenomenon and noumenon, in rational thought, are not always identifiable, at least for the first, as for the second, they are never identifiable. The phenomenon is the thing as it appears to our mind; our mind can set benchmarks, say to which set the phenomenon belongs if that is possible, and the notion of belonging is already a location. To speak of a "thing in itself" is the negation of all references, whether in ordinary space or in an abstract space as defined in mathematics.

The brain uses these patterns; they do not develop over time; they are already before any consciousness of their existence.

You have to bet on what you find; the attitude contains that. It must be understood, and this is difficult for the rationalist researcher to recognize, that the observer, if he is a true researcher, knows <sup>5</sup>. Of course, we must not separate by a time scale the fact of knowing and that of being; both, knowing and being, are presented in tension <sup>6</sup>. This is another face than that of the tension between attitude and moment. We will never have to do with the tension but with its faces, from which a sheaf of paths is elaborated which will go from these faces to the intention. Thus we will have multiple ways, paths. All are possible, used.

Then from each path may spring another sheaf; everything will be built like fireworks and this in the very moment.

We can say that awareness (which is in time) emerges from this instantaneity. The tension also appears thanks to this image: the human brain behaves like glaciers on rocks; they forge them. When a brain in society is hampered by that society, it gets pushed, twisted, and something else comes out of it.

So there is tension between a brain and society. But how can we consider society, an abstract concept? The society we are talking about here is the one representing the rational world. Society and world are thus two poorly localized concepts. Society is the set of humans in industrialized countries, these humans united by nature and laws, customs; the rational world is the whole of the individuals of these industrialized countries but with in addition the laws, the relations between individuals; one can still put multiple characteristics into the expressions today's world, rational society.

<sup>5</sup> An anecdote linked to Albert Einstein shows that he knew his hypothesis true long before it was verified [ii], There were two large expeditions organized in February 1919 to observe a total solar eclipse, in Sobral, in the north of Brazil, and the island of Principe, in the Gulf of Guinea. They both demonstrated that Einstein's calculations were correct and that it was therefore necessary to abandon the conception of the world which had been imposed since Newton.

Dina Marianoff reports this: "One of Einstein's colleagues from the University of Berlin was there by chance when the photographs of the eclipse were in the hands of the researcher. He said to him, "You must be happy, you have the proof of your theory in your hands." "A proof?... a proof? repeated Einstein with that surprised, questioning air that always gives the impression that he is only a visitor on earth. " A proof ? They are the ones who needed it! I wasn't looking for it! "".

Let us also quote this other anecdote of Antonina Valentin relating the memories of Elsa Einstein: Einstein looked at the photographs (they gave the proofs of General Relativity) with a surprise which changed into a joy illuminating his features "It's wonderful, it's truly wonderful! ".

It was entirely believed to be his triumph. When the importance of this confirmation was explained to Madame Einstein, she ventured, shy: "How happy you must be, Albert! ". And, Einstein, his eyes still riveted on the photograph, replied: "I am delighted! ". But he immediately added: "I would never have believed that photographs could reach such perfection." So he was talking about the quality of the shots.

<sup>6</sup> In the case of rational vision this is not generally apparent.

In these cases they will be assimilated by rational thought, used in this thought <sup>7 8</sup>; they will be in a certain sense identifiable because describable by elements belonging to the usual language. Although the notions of a rational society, of a rational world are not defined

Q

with precision, they enter into the usual thought. These notions, while not entirely recognizable, can immediately be associated with their container, which is perfectly recognizable <sup>9</sup>. We thus confuse them with their container as we confuse the forest with its container which is the set of trees sufficiently close, sufficiently bushy and leafy, in sufficient number. But we will see later that the concept of forest has something more that makes it not part of usual thought.

The tension between the brain and society can be seen as caused by one of the faces of intention, this intention which will be presented later, the importance of which is fundamental.

You have to bet on what you find, discover: the attitude contains that. The bet is not taken here in the sense of the word intervening in the game, but in the sense of the one who wants to know in order to hear and not to win and dominate the others, or at a pinch win for him if he fixed a goal, although he must forget the goal to devote himself only to the path.

It must be understood, this is difficult for the rationalist to assimilate, that the obs, if he is a real researcher, knows (refer to footnote 5 of page 1, note linked to Albert Einstein).

Naturally we must not separate by a time scale the fact of knowing and that of being. Both, knowing and being, present themselves with such intensity <sup>10</sup> that they are in tension.

Carlos Castaneda talks a lot about attention[iii]. It is for him the spirit, which is above all abstract, "the dominant force of the Universe ... the force which modifies things, or maintains them as they are". The intention changes the state of the obs or if we consider this "vertical thought", intention and state are in tension. In the intention there is more than the

---

<sup>7</sup> rational or usual.

<sup>8</sup> a concept emerges little by little in the mind of the child, settles there without definition and he will be able, as an adult, all his life to use it without further knowledge, and quite appropriately.

<sup>9</sup> We can thus introduce the non-locatable notion (known as delocalized), of the enel of a society. It should be noted that concepts related to the non-locatable are used in everyday thought; this is because the human brain does not naturally construct a rational world; moreover, ordinary thought has become very powerful, and it absorbs all the concepts of the rationalists better and better, more and more in order to stabilize itself, because even in ordinary thought, areas of instability appear, fractures which must be resolved. to fill in.

We will not say that everything that is identifiable constitutes rational thought but that everything that enters into this thought will one day be able to enter into a rational context and then the non-identifiable character disappears to serve absolutely rational results. We could say that rational thought - the rational field of coherence - sets up terms, concepts which by a certain tincture are elements of this field of coherence.

<sup>10</sup> About the rational vision it is perhaps not possible like this.

to want, there is the will in becoming; but wanting to become is also in the moment, it is not spread over an interval of time.

The other is no longer potential, it is <sup>11</sup>: it is a present of extraordinary richness. Everything that we will see later, such as “the network of the future” is fertilized by this present; this present overflows from itself to exist in this network. The present is diluted in the moment which is partly delocalized; the moment placed in this moment, becomes an emergence; the moment is rethought differently; from a time interval element it becomes a memory of a location.

Castaneda writes again “The intention creates buildings in front of us and invites us to enter them. This is how wizards understand what is going on around them. Sorcerers then speak of symbols. Symbols are the usually understood return to the present of the cathexis of intention.

The intention imposes representations. Some are easily implemented, this is what can happen for example with the placebo effect, well known to everyone where effects are noticed, attributed to other so-called psychological effects. In the case of the placebo effect, everything it contains is put in place by the one or those who make the experience a representation: the remedy that will be given to the patient is supposed to contain the drugs that fight the evil. The patient will enter the game but he is deceived: the caregivers want to distort a story. This therefore corresponds to another story that is taking place, what we will call a path. The patient's confidence in those who care for him enters into his intention, it is the same with his desire to heal. In the same way the intentions of the doctor, nurses who took part in the experiment intervene.

This explanation presented here is not the only possible one. It is also slightly incomplete; it will be presented later in the course thanks to the introduction of new concepts. Then we will also find cases where several explanations are possible simultaneously. Each explanation is attached to a path, a path. We can thus have several possibilities, what we will call a sheaf of possibilities. In this sheaf, all the ways will be used; tensions may appear between the paths of a <sup>11 12</sup>

<sup>11</sup> Here we are faced with a “face” of thought: “I am he who is”. Awareness of this thought comes afterwards.

<sup>12</sup> If we test the water that is supposed to contain the drug according to the methods described in [4], we find in this water characteristics that it did not have before the establishment of the intention of the caregivers. The intention of the patient takes up these new characteristics of the water to amplify them, multiply them, stabilize them and his condition will go on improving, the product by the intention being supposed to treat the patient. It is a face of this intention that comes into tension with the intention of the caregivers and the new characteristics of water. There is no more cause and effect when tensions arise. The water, for example pure at the start, is impregnated as in the case of a homeopathic dilution.

sheaf or between a sheaf of one case with a sheaf of another case. So everything swells, develops, but not in an evolution indexed by time, in an instantaneous existence. The intention can be associated in certain circumstances with a neighborhood. So if we choose a plant that can heal; what we are going to treat will depend on a neighborhood which is not that of the plant but of the one who has the intention, and the neighborhood of the one who has the intention could become a neighborhood of the intention.

On the subject of the moment, it is necessary to know how to identify the moments, for example “to die not when one wants but when one must [iii] (volume 8)”.

The “implacability” of the nagual [iii] presents itself in several facets. It is like a tool that adapts to several uses. The functionalities of the tool are diversified and allow it various uses.

The tool thus has multifunctionalities, multifunctionalities associated with a technical object or adaptation of the tool to other technical objects.

Implacability is an attitude. The attitude characterizes a level of intention linked to the nagual [iii] (volume 8).

Castaneda emphasizes intention through the eyes. We are faced with the power of the gaze. The human being can convey his intention through the eyes, but that is far from being the whole intention. The eyes <sup>13</sup> are both the reflection and the brilliance <sup>14</sup> of stories happening quite elsewhere. They make it possible to transport into the usual thought (usual or rational field of coherence ) <sup>sensations</sup> belonging to the other thought (other C. of C.). Between reflection and brilliance of the eyes there is tension <sup>16</sup>.

Let's continue with the notion of intention. Carlos Castaneda used it in [iii] (volume 8). It should be noted that Don Juan, the Yaqui sorcerer who initiates him, does not have the adequate language for what he wants to make Castaneda feel, but he has had a remarkable training; thus he can transmit by gestures, periphrases, examples evoked or experiences carried out in the field. Don Juan is like the ancient sorcerers of whom he speaks "He is not focused on thought, he leans towards action"; on the other hand compared to the old wizards, there is in him an attempt to put an understanding in place. It does not achieve coherence but it transmits. Let's see what he says about intent:

seen in ordinary thought. But the eyes are not comparable to a system of lenses.

<sup>14</sup> reflection and radiance: concepts developed and used by Goethe.

<sup>15</sup> Field of Coherence: abbreviation: C. de C. .

<sup>16</sup> This tension is an “equimsey”, which will be explained later.

"...there exists in the universe an immeasurable, indescribable force, which sorcerers call intention, and that absolutely everything that exists in the entire cosmos is linked to intention by a link of communication... "... sorcerers drew knowledge directly from intention, without the embarrassing intervention of spoken language" (this is of course the spoken language of the usual C. de C.). "Intention is the universal force <sup>17 18</sup> that makes us perceive". We don't become aware because we perceive, in fact we perceive because of the pressure and the intention of the intention. It is the intention which is put in tension with itself.

A healer from Berry said during a television program "It is the intention that makes you succeed when you want to cure a patient".

He perhaps did not foresee the deep meaning of it, being too implied by this intention used in current language which expresses a will in an action to be carried out and this, in a setting up.

The intention as Don Juan feels it, and presented by Castaneda, seems to express itself thus: it precedes the thought and is found in the thought. It is both a primer and a progenitor [iv] and [v]. We can say that the intention sinks deeper and deeper into the depth of its own intention [v]. All this, thereafter, will be expressed in an adequate language [vi].

<sup>17</sup> Don Juan uses the word strength because he uses everyday language to convey a message.

<sup>18</sup> Primer and progenitor will be developed later.

“True scientists are poets and imaginative.  
Without them, Science would not exist.  
The others are accountants and grocers,  
they don't find out.  
And besides, that life would be boring without imagination...”

Paul Emile Victor

Reminder : A lot of isolated researchers, remaining isolated all their lives and unknown to everyone, their documents, notebooks, notes, ending up in attics when they died and after being thrown away during family moves, were attracted by the eifs and have given approaches that are not very similar, at least when it comes to classifying them. This comes, as previously mentioned, from the representation that the researcher gives himself as well as from his tacit knowledge. Some (and this is true for the most part) did not even deal with the notion of state, which we will see later, which led them to a simplistic (but sometimes useful) classification of what they called the “good waves” and the “bad waves”, or the “beneficial fluids” and the “evil fluids”<sup>19 20</sup>.

Enel (Prince Skariatine) had, after his return from Egypt, around 1923 given a classification; to do this he had created a correspondence between the visible part of the electromagnetic spectrum, to which he added the infrared and the ultraviolet, and the eifs. For him, it was not confused, but essentially related to colors. He could have chosen a completely different scale. He himself also classified them into acids and bases; thus we find:

|                                          |                  |                                   |
|------------------------------------------|------------------|-----------------------------------|
| Red(R)                                   | Blue (Bu)        |                                   |
| Orange (O)                               | Indigo (I)       |                                   |
| Yellow (Y) <i>Y said positive colors</i> | Purple (Vi)      | >so-called negative <sup>21</sup> |
| Infrared (IR) <i>or acids</i>            | Ultraviolet (UV) | <i>or basic colors</i>            |
| Black (N) >                              | White (Bc)       |                                   |

He found a correspondence between the "colors", the various elements of nature and the organs of the human body. He used this correspondence to heal and had spectacular results. He summarized this in his works, we will not develop them further.

On the other hand, these correspondences are interesting because they bring together the fact that from the moment when we look for a correspondence, in an unexpressed way, we place two sets facing each other, and the ordered set of emissions (because we can place them on a circle or on a line), in this delocalized domain of the eifs, flattened on that of the organs for example, entails an operativity on the elements of the set of organs.

Enel could have chosen another scale, for example, electric voltages, electric or magnetic field intensities... and on certain divisions of the dial say: I have a

<sup>19</sup> This denomination of “good waves” and “bad waves” nevertheless makes it possible to test a place and even to rebalance it. It is a very simplistic description but the dowser can make a representation for himself. It will simply be difficult to transmit. Moreover, it will not adapt to the use of eifs for industrial purposes, for example.

<sup>20</sup> Enel had realized that the “emissions” were not electromagnetic waves, while some who followed him did not have his lucidity.

<sup>21</sup> Colonel de Rochas seems to have discovered 2 of them, one blue and one red, but he is not sure that they were eifs.

emission every 15 volts, every 5 amps, every 10 gauss ... Bovis and Simonetton have moreover built devices which supposedly measure the wavelength of the human being in angstroms (for example 8500 Å for an individual will mean such a thing: he will be more or less in good health). We will talk about these arbitrary scales imposed in the domain of eifs later.

We did not mention green in the list given by Enel; he had noticed that there were two; one was named positive and the other negative. It is this negative green (actually VE) that mummifies meat, fish, it stops decomposition and kills all microbial life. It is found in the great pyramid of Cheops, likewise it is emitted by the statues of Easter Island.

Note that Jean de la Foÿe [vii] used discrete spectra but also lines of continuous color spectra. On the other hand Enel only used the discrete spectrum but he had to be aware of the continuous spectrum. It should be noted that people using a discrete spectrum and others using a continuous spectrum may not give the same results after studying shapes; each of them will however be right; it all depends on the performance. There will be no function related to a probability to indicate results obtained from the discrete spectrum and reported on the continuous spectrum. Moreover, other researchers, just as isolated, arrived at completely different classifications which gave them valid consequences both in medicine and in the detection and rebalancing of harmful places and dwellings.

According to what the obs puts as concepts in its model, it recovers phenomena: thus it is the case of the od, the auras, the Kirlian effect, the orgone. Then all this passes into a knowledge on the scale of a people or even planetary; care must be taken that this passage does not distort the phenomena. But let's not forget, depending on what the obs puts as a concept in his model, he recovers one or more phenomena<sup>22 23 24</sup>.

<sup>22</sup> R. de Lafforest often talks about it in his works. Bélizal, Chaumery, Morel have studied it although the description of the discrete and continuous undifferentiated spectrum belongs to Enel. We will thus have the eifs of the EFF level of the discrete or continuous undifferentiated spectrum or of the differentiated or continuous discrete spectrum of types E and M. We can moreover not consider the continuous spectrum as a complement of the discrete spectrum - This is a point view acceptable, it all depends on the representation -.

<sup>23</sup> Jacques La Maya [viii] has also adopted a simplified classification using the denominations "good waves", "bad waves".

<sup>24</sup> The eifs and we will see later, the yews, the avaecum, the wyverns, the arkhams, the mahkras... correspond: to a more or less advanced delocalization of the form or of the system of forms but also to the fact that the obs is in front of the form and that he has considered it to be in the ET (usual point of view) or partially inside, and also to the following fact: the obs, while knowing he is an origin, flattens his vision, that is to say considers what surrounds him existing outside of him. This position of the obs is found in the usual C. of C., but the fact of having become aware of it places it in a trace of the other C. of C. in the usual C. of C.. It is a bit like a shadow of the other C. de C. on the usual C. de C.. The second C. de C. accepts

## *The form*

The concept of form is presented differently according to the times. And here, the epochs themselves are not envisaged according to the usual vision. They are not perfectly defined. We will not talk about it as in art, literature, from the 17th<sup>th</sup> century , 18th<sup>th</sup> century , etc...

The times will not be perfectly defined. They are like moments - see Fascicle 9 of the 1<sup>st</sup> level - their edges leak.

But when we think about this concept of form, we try to marry - and not impose as we do in rational thought - the thought of people who belonged to those times.

In the usual C. de C. the form is immersed in the space-time structure. The ET is given a priori, in first truth, the forms come later.

We don't think of forms that way. For us the form emerges or immerses itself in the ET structure. It is as fundamental as this structure.

The form thus becomes fundamental; it is both a landmark (we rely on it to consider its surroundings, which it is not) and difficult to identify (if it is not completely present in the ET structure). It may not be completely localized, that is to say not completely present in the ET, that is to say still not completely describable in this structure.

But in addition the form is the “Way”, which will avoid speaking of the form and what is not the form. At the same time as we set up the model, the representation or representations, we must follow the spirit in its approach. The mind conceives the form and then contemplates it. It is more correct to say that these two actions are only one. As an image, we can rely on geometrical optics for which object and image are linked but in addition, here, object and image would be one; thus one can consider the model as the object and the way as the image.

From the path one draws the necessary discipline of spirit when one leaves the usual C. de C. - discipline which is not expressed; it is implicitly included in the way - so as not to \*

---

this position as soon as the obs became aware of it. It's not an excess of language or an extension, it becomes an operativity. This is all the more valid since one cannot arbitrarily think of a human being as an origin (that is to say, launching his C. de C. in which he finds himself as well as everything that exists). Now this can only be lived by the obs and then there is only one obs. But human thought seems forced to choose, in order to define itself, to hold this position in which the obs launches its C. de C., despite knowing it, it cannot use it in this way. And this impossibility of use is the “thinking sheet”, the noosphere of Teilhard de Chardin [ix]. Thus a blockage on a human scale is creative and operative for the human species.

<sup>25</sup> Space-time: ET.

fall into phantasmagoria, the latter not always belonging to the domain of the absurd although often they do.

According to [i], it is the state under which we perceive something; the notion is likely to take on all sorts of forms and aspects. The notion of state appears here, but when we speak in the following booklets of the state of a form, we will not retain this definition. When we speak of "geometric shape" it is the external configuration of a surface, a volume or else in the case of a curve, it is the aspect of the curve but the aspect without sensation .

We must, when considering forms, take into account the interior as well, the composition, the material. We will therefore have to think about form and material.

The word form is used in metaphysics in very different senses which vary according to the authors, as opposed to substance, essence, matter. In a general way philosophers designate under the name of form the ideal principle of beings as opposed to matter, which represents the underlying chaos which is organized by the formal idea <sup>26 27</sup> [i].

Note that the word essence does not correspond to a locatable, localized notion. It is linked to the global.

Also called forms are the ritual words that accompany a sacrament: this is what is usually expressed by "the form of a sacrament". This last meaning, considered in [i], is important for what we develop. This form, as we shall call it, is largely delocalized. G. Simondon [x] writes: "the notion of Form, in all the doctrines where it appears, plays a constant functional role: that of a structural germ possessing a certain directing and organizing power; it supposes a basic duality between two types of reality, the reality which receives the form and that which is the form or conceals the form; ... the form is consistent with itself". The notions of archetypal form of the Platonic or hylomorphic genre have been much discussed.

G. Simondon introduces coherence [x]. The psychology of Form developed in the psychology of expression considers meaning as primitive reality, in fact "meaning is given by the coherence of two orders of reality, that of individuation and that of individualization" according to the thought by G. Simondon.

<sup>26</sup> This point of view will not be considered.

<sup>27</sup> **Hylomorphic**: is said of an individual generated by the meeting of a form and a material and the other point of view: **Substantialist** : being consists in its unity, it is given in itself, it resists what is not itself.

Both points of view, points out G. Simondon [x], "assume that there is a principle of individuation prior to individuation capable of explaining it, producing it, driving it".

*Individuation* is the set of particular qualities which constitute the individual and distinguish him from another. This individuation is elaborated from a principle.

*Principle of individuation* : among the scholastics, what gives a being concrete and individual existence.

Let us point out the term individualization which is different from individuation.

*Individualization* is the action of individualizing but also the effect of this action and also the state of the individualized object. In [x] we find the following example: the individualization of the penalty for the same offence, that is to say the application of different penalties to the perpetrator or to the perpetrators and accomplices, taking into account the elements individual to each of them. We can say that individualization comes after individuation. Acts are considered according to what has been judged on individuals.

For Gilbert Simondon, the **meaning** is given by the coherence - a fundamental concept in this course - of two orders of reality: that of individuation and that of individualization. Coherence - this word seems well chosen here - is placed like a checkerboard on which the forms and events move and are ordered. Coherence presents itself in this context as a <sup>28</sup> \* 30 surdans .

In this course the word coherence, thereafter, and in the expression “field of coherence” is not a consequence but a first truth.

We thus note that the compatibility of the two orders of reality, individuation and individualization, is expressed by what underlies the whole: coherence.

We can consider the point of view according to which we have two faces of coherence such that one underlies individuation and the other individualization; the incompatibility of one face with the other causes a collapse and a new face of coherence emerges. The collapse is experienced as an implosion that would generate a creative world.

Coherence can be considered as a monad. In the monad, we speak of principle and source <sup>31</sup> . Often principle and source are not expressed, and everywhere we speak of

<sup>28</sup> **Scholasticism** : what is taught according to the ordinary method of the Schools of the Middle Ages. Pejoratively, that which deals only with form and which remains distant from what attaches to observation and life. In Europe, Scholasticism was taught between the 10th and 16th centuries . She seeks an agreement between reason and revelation [i]-

<sup>9</sup> **To individualize** means to consider individually, to separate, to abstract from the species.

<sup>30</sup> This will be developed later in the course.

<sup>31</sup> **Monad**: Leibnitz's definition alone is retained; the monad presents itself as a simple and irreducible "force", which contains within itself the principle and the source of all its actions. That is to say, the monad contains what it is. Let us then consider what will be two faces of the monad: one the principle and the other the

monad, for example Louis Boutard's aether monad [iv] and [v]. This researcher did not explain the principle and the source because he did not know the thought developed here, called “arkalian thought” <sup>32</sup>.

From concepts put in place, we can generate what seems fundamental like coherence. We will no longer necessarily set up, as in the usual C. de C., one or more basic elements and a construction from these elements. We will be much more faced with an existing system in itself, sometimes even a monad containing one or more monads.

We see that this construction is not a descriptive rational approach; the constructions which will follow starting from concepts such as the equimsey, the dynamic duality, the overlapping, will set up elements and other notions which will form monads or something else.

According to G. Simondon [x] the form is defined as the state towards which the system tends when it is in equilibrium. This equilibrium may be stable or metastable. “What makes the right form is not that of geometric description but that which establishes a transductive order within a system of realities comprising potentials. This good form preserves its potentials by compatibilizing them; it is the structure of compatibility and viability”.

The form becomes a generally metastable system to individuate itself. The form emerging or immersing itself, as we envisage it, is not totally incompatible with this point of view <sup>33</sup>.

The form can be considered as a metastable system in this emergence and immersion. Thus we see that the formulation of form in emergence or in immersion makes it possible to put in construction two ways:

, form, system en l'ane-I-ue-s-individual  
metastable state J

e metastable system en | way II  
emergence or immersion J

source. There is a tension between the two faces. Moreover, principle and source are linked in another way. Later in this course we will express it by what we call a “forlia”.

<sup>32</sup> Arkalien, arkaliene: comes from the name ARK'ALL created by Jacques Ravatin in 1980. ARK'ALL is the name given to a research group which is the offshoot of the TOTARIS association. The latter has been replaced by the association DECALUM which proposes the Study of Material and Intellectual Systems escaping the usual logic.

<sup>33</sup> According to G. Simondon, the notion of form can be replaced by that of information. We will not follow this path because information is an intuitively rich notion but which loses a lot in its formulation which is linked to Shannon's definition and thus to entropy. Entropy only makes sense for localized systems.

But tensions can be set up between path I and path II. By watching oneself think, one can follow the cerebral processes that one uses again and make new paths appear.

The concept of path has many faces. It is thought out abstractly and we tend towards the multiplicity of the way, a face. Or from an element of multiplicity, using the concept of face, one establishes the abstract concept of way. This constitutes two more faces of the path. These seem new because they have been elaborated after the fact; they are in the cerebral approach which, when it expresses itself, puts in place much more than it seems to have done. The system put in place is both a **starter** and a **parent** of itself.

The monad is also primer and progenitor; that is to say a system that we will designate as “AG system”<sup>34</sup>.

In AG systems there may be one or more voltages between A and G. This will be considered later. Let us consider a concept in the usual C. of C.. This concept has a meaning in a certain area of C. de C. But we can, for literary effects, use it in other areas, analogies arise, analogies of situation, of construction of sentences, puns, sound effects. Thus this passage from a domain for a word to another domain will constitute a path. We will say that we have carried out a “structure transport”. This track that we have at our disposal, we will use it in a more general way by carrying out structure transport on the track. We will thus pass from a domain of the usual C. of C. to a domain of the other C. of C.

The other C. of C. is difficult for us to access, so by this process of a domain like the one with which we are associated by the word, we pass thanks to this new way to another domain; this other domain is generally not known and the process will be further extended because the transport of the word will cause the establishment in the other C. of C., of a domain about which we know almost nothing or even completely unknown to us.

G. Simondon speaks of Field of Form “the form which contains within it a certain field”; and he calls this form “good form”. This field of form is the fact “...at the same time of an isolation between two terms, antithetical, contradictory, and yet in correlation...”. This field must be able, still according to G. Simondon, to produce energetic effects if something is introduced into it. He recalls Plato who wants a form to follow a dyad or a “plurality of dyads coordinated together”. There is both unity and multiplicity

<sup>34</sup> The AG type system will be presented later.

“One and multiple, meaningful connection of the one and the multiple, this would be the structure of the form”.

We note that the assimilation of a form, as it appears in Arkalian thought, is only done in stages, not necessarily attached to functionalities since most of the forms that we are considering are largely delocalized; it does not present itself as a transduction which is a process where one relies on the last step to build the following one; we are faced with emergences that are put in place by unity, that is to say what will be the form in the process of partially emerging or even never emerging enough for us to be able to describe it with our five senses; in the latter case one can test such a form, very correctly; we only know its properties. The properties gradually become the form; other properties are beyond suspicion; they can become perceptible to the obs when it comes to the implementation of new concepts. These concepts are in the emergence of the construction of the form, they do not come afterwards although they appear afterwards. The form in the process of being constructed carries a leak in its existence; it is this escape which makes all its richness and which expresses its unity, because unity is not only the establishment of coherence between concepts - rediscovering the coherence that we went to draw from to build the C. de C. at the beginning - the form is both stabilizing and creative.

Forms can be testable, untestable (some, but rarely meet the two qualifiers if we agree to leave the usual domain). They can also be overlapped, in equimsey - or even overlapping and equimsey can occur simultaneously, also in dynamic duality - and all the above can be combined -; again there are the open forms, of the transfer type, forms which depend on the moment, non-locatable, barred, with variable eifs, the forms linked to the aether. The list is not exhaustive. Let's come back to the so-called “moment-dependent” forms. By working with certain forms, we noticed that what we could detect on them, what was linked to them, was not stable over time <sup>35</sup>. This may be due to special states <sup>36</sup>. But this is not always the case and it was necessary to become aware of the forms produced at a certain moment, and not at a certain time; the expression here is very important: "at a certain time" entails a time interval and this in a certain place, therefore entails the conception of a neighborhood in the ET that is fairly well delimited, moreover fairly well localized since he is in the ET. So

---

<sup>35</sup> J. Ravatin

<sup>36</sup> J. de la Foÿe

that the moment will suggest a flight of landmarks at the limits of the time interval (we can no longer speak of a linear unfolding of time, simply in the moment there is something localized, like an anchor point, the same in the 'space).

The moment is linked to the context, to atmospheres; to intentions; let us project the word moment as we have envisaged it onto the background constituted by the whole {context, intention; ambiance, atmosphere} then we will have a halo <sup>37</sup> as long as we also agree to call “moment”. It is this moment that we mean when we speak of forms that are dependent on the moment.

Living beings depend on the moment.

The Ark of the Covenant was thought according to the moment (it also contained the first Tablets that Moses broke, those which were written on both sides).

The first Temple in Jerusalem depended on the moment for some of its dimensions which had been thought out from a unity linked to the moment. We cannot in this case compare this unit to another as long as the Ark, the Temple are not finished, this is a reason why, during the time of construction, it remains secret. Thus measuring the Egyptian cubits with a meter is useless because if we reproduce the shape - as we say "exactly" - it will not be exactly the shape of the past; it may or may not depend on a moment, but it is not the moment of the first form. Besides, the first Tablets depended on the moment of the fact, in particular, of their location on Sinai. Moses, breaking them, removed a moment with which, as a form, they were associated. By placing the pieces in the Ark of the Covenant which was also linked to a moment, Moses was able to find for these pieces the moment linked to the location of the Tables. This caused the Ark containing the pieces to be bound at two times. A moment-dependent shape retains its properties. If it is reproduced at another time, it will have other properties while appearing identical.

One can thus find a unity with a view to the realization of a form which will have to have such and such a property; this unit of measurement should under no circumstances be compared to another unit, for example the meter or its multiples and sub-multiples. Thus, a wooden parallelepiped with astonishing properties, stable over time, can be produced.

In alchemy it is necessary to take into account the moment, from where a certain number of grimoires become useless. They only have historical value; the one who has understood this operates in a true supraalchemy.

<sup>37</sup> These concepts and writing will be explained later in the course.

In the teaching of some initiates, thoughts of those initiates cannot be taken up by other people at any time; as forms these thoughts depend on the moment. The disciple is the one who is close to the Master, formed and chosen by him, and to whom the Master gives the power to resume the teaching, at another time perhaps, but keeping "all the substantive! as Montaigne would have said.

Is a non-time-dependent form a degeneracy of a time-dependent form even though feeling unconstrained by time gives a feeling of greater freedom? One must be wary, in the domain of forms, of what one thinks one gains; one can, by gaining too much adaptation, as one does in rational science, lose a fundamental essence; in a sense a moment-dependent form is more an emergence than a form that one might call 'free'; which does not mean that a free form is not in certain cases as delocalized as a moment-dependent form.

"Non-locatable" forms are forms for which only one index is available, which is generally localized. It is this index which is used to use this form; it is accessible to us only by this index. A non-localizable form is itself more or less close to localization; it seems to "oscillate" towards a localization that is called form-index. An example of such a shape is obtained by planting in the ground, vertically, two iron rods, circular, of the same height (circular section, height 1.80 m. or more) so that the plane formed by the two rods is oriented northeast/southwest. So we detect a non-locatable shape whose two pegs are like a start of localization. This shape can serve as a good rebalancer and emitter in a certain neighborhood; these properties can be further amplified by placing a block of quartz on the ground between the two rods (not all minerals have this effect).

Another example of a non-localizable form is boron hydride - we are in the microscopic domain - of formula  $BH_3$ . In reality it is placed in the usual C. of C. in the form  $B_2H_5$ .  $B_2H_5$  is an index form, well localized here.

The "barred" forms were discovered around the 1980s during research. Let us now see such a form. For this, let us draw in a plane a rectangle ABCD with center of symmetry O as well as the two axes of symmetry, perpendicular to the sides,  $x'x$  and  $y'y$ . Let us now draw the line  $t't$  passing through O and making an angle of  $-23^\circ$  (or  $-22^\circ 5'$ ) with  $Oy$ .

Let's erase the axes and the symmetry. This figure will be called "barred form". It is interesting to note that this form emits at high

g Taofel fields. A matter of direction

in the plan arises which we will not discuss in this course [iv] and [v].

<sup>x</sup> A rectangle can be replaced by a

square; the more we tend towards shapeless forms,

C the more difficult it is to cross out the form, but it is

generally possible. You can cross out a circle; it

is then necessary to be very careful to impose the "North

said of form" [iv] and [v].

A barred form can depend on the moment.

Let's bar a rectangle placed vertically, the North of shape is then replaced by the ascending vertical of the place. Depending on the position we have in relation to the plane, the shape will be crossed out or not. Thus two observers will have different opinions as to the form. Which is right? If the barred form has effects on the environment, for example the vegetation, what will be chosen by the place, ie the form, seen as barred or not barred? Both observers are right; they may very well disagree. In the same place, two realities exist, one is chosen; so does the environment. But the two realities which each come from distinct representations can very well be in tension under the multiple faces of the tensions of which we will study some thereafter.

The shapes with "variable eifs" are also found in the case of a regular star pentagon where at each vertex there is a segment of constant length and making the same angle  $a$  with the tangent to the circle circumscribed at this vertex. The period  $T$  is a function of the angle  $a$ . Check this in practice.

Note : The pendulum above such a shape turns then its movement slows down, then increases again, and so on.

"Decal type" shapes:

- Consider a form  $F_j$
- Let us impregnate or dilute this form in a bath, an atmosphere; this will give  $F'_1$
- Let  $F'_j$  be placed on a support, this gives  $F_2$

<sup>38</sup> See the rest of the course.

Suppose that  $F_2$  turns out to be  $F'_2$ .

We will say that we have gone from  $F_j$  to  $F'_2$  following a “decalco type” process.

$_2$  can then be combined in multiple ways, by tension, by a T AG system, which will create an atmosphere.

We talked about dilution, let's see the dilution of existence. The dilution can be realized in the existence with reference or without reference; we therefore have existence diluted in existence. This generalizes the notion of dilute form.

We will see the forms related to the aether in the following papers on the eifs, the avaecum, but we need these concepts and results to present this type of forms.

Exercise : We have seen the barred rectangle. Let's place it vertically with its bar.

- 1) Check that it is still "crossed out" and that eifs are detected which are at the EFF level and at other levels.
- 2) Suppose that in this position an observer arrives on the other side of the plane. Check that it is no longer crossed out.
- 3) What do we detect around this vertical plane in which the barred rectangle is located?
- 4) What can we conclude about such a situation?
- 5) What will a plant that is close to this vertical plane choose?

Answers :

- 3) When we are on the side where the angle is  $-23^\circ$ , the rectangle is crossed out; we detect eifs which are Taofel fields - which we will present in forthcoming booklets - and this on both sides of the plane.

When we place ourselves on the side where the angle is  $23^\circ$ , the rectangle is no longer barred. We detect eifs at the EFF level but no Taofel fields.

Conclusion : the nature of the eifs depends on the position of the observer.

- 4) The plant, living system, chooses according to its nature, a position of the observer; whatever her position. This can change over time, from one performance to another. Perhaps even tensions between the two possibilities may arise and set up new possibilities.

If we come back to the human observer, what he detects in front of a form may also be the result of tensions.

The observer seems to be faced with a problem of broken symmetry. Which is even more interesting. What must be achieved is what is before the breaking of symmetry.

Forms allow access to this “before the breaking of symmetry”. For example certain Hebrew words, more generally certain flat shapes, water in which a certain message has been put, etc...

In the couple man-woman (HF) the difference between F and H is the result of the breaking of symmetry.

We have to go back to the Bible on this subject and we begin to understand what it is.

### Conclusion :

The realm we are entering is truly confusing. This justifies the remarks to which we returned in the 1<sup>st</sup> level course, where everything, absolutely everything must be carefully observed before drawing conclusions.

There are many other situations like this.

## */ . Introduction*

Ancient books are full of bizarre stories, observations that seem incomprehensible because they are absurd; the old people talked about it in the evenings, the grandmothers told these stories to their grandchildren. All oral or written transmissions are full of them; but we must not sweep away tales and legends under the pretext that they are only nonsense and stories, thus they are considered by a too hasty judgment and by people who want to be strong, rational.

We must then ask ourselves if rational thought is adequate to allow ourselves to bring out a reality, a likelihood of a legend, a tale.

Of course, we must not deduce from this that any story written or told is full of hidden mysteries, that a hidden key too must, if it is implicit, open onto a marvelous world. Thus many so-called alchemists speak in muffled voices of mysterious texts, comprehensible only for them and draw from it an attitude of rejection and disdain vis-à-vis others which - they have the impression - allows them to value them vis-à-vis live on others. They know - so they think - and the others do not know.

Let's forget those failed alchemists - fortunately not all alchemists are like this and a few were exceptions -.

We must not forget that human beings have the right to dream, to write novels, to tell stories. But some dreams are blossomings of flowers, each representing a deep human sensation. This was the case of Jules Verne who imagined in the deepest sense of the term: he was already in his creations!

In any story we can set up a path to extirpate, in the course of this path, from this Way - in the sense that we spoke of a way in the 1<sup>st</sup> booklet of this 2<sup>nd</sup> level - a knowledge which will reveal the content of a decryption if it is a coded document, a study of the human mind because any thought, any expression of thought, is itself a "face" of a being, - the one who has created the text, the story - of a form - form in the very broad sense, not only in the sense of material form, so a thought can be a form -.

Above all, we will not stop at the usual studies of an author's character, sensitivity and quality based on his text. Theses, newspaper articles, reviews on these types of studies are legion.

The study of the work of Balzac, for example, is a source of stories which, in addition to the interest that each novel brings, describe the mores of a society and the characters and actions

of characters. But we can consider this work quite differently. It will intervene in the reader's brain as a springboard to something else - we can say that it is a source of inspiration -.

Thus these works like "The Centuries" by Nostradamus have given rise to multiple interpretations. There were absurdities but some contained a fundamental message: it seems that this text is a cornucopia from which many revelations could emerge. It is then necessary to realize that such a text or even that the work "The Bible, The Secret Code" by Michael Drosnin are constructions which are not made in so-called rational thought and that by rational thought, in leaning on these writings, we find ourselves faced with a multi-faceted system. The decryption processes are all indicators of these texts. They are lit each time in a different way.

The excitement of the one who discovers a hidden meaning is great. Everything seems to come together in him. He sees in it a coherent construction which will go more and more in this direction as and when the investigations on the text.

And for the future, these decryption texts and processes become mancies.

Tip: This introduction should be read carefully and re-read. The student in this field, the reader, must gradually become impregnated with the thought in which we introduce them so that they train themselves to think differently and to even be able to contemplate rational thought without having to support it as this is the case when it is considered as unique - thus it is the case in our society which wants to be modern and in continuous progress -.

In each booklet, one will find such studies. It is therefore necessary to study them well - to read and reread them; so is it necessary -. They are like the exercises and problems presented in each booklet.

Students need to get off the "beaten track", find themselves going against the current and doubt the certainties that have tacitly invaded them; to agree to open up to new thought.

It is necessary to consider as a very particular case the research traditionally accepted, and by its form of thought, and by its methods as well as its consequences, technological achievements, the economy, sociology, etc. all of which rely more and more on Aristotelian logic, on the "Cartesian" spirit, both of which, moreover, are useful for comparing and classifying.

But in any research, one should not classify too quickly because one can break something very deep by wanting to see too well: a classification always has a horizon that it cannot reach and this horizon may very well not be in agreement with the classification system used and disappear when the induction-deduction grid falls on the observed domain. This horizon is the index of an instability, which is not considered admitted in the usual thought, but which manifests itself for the one who is aware of another form of thought.

In the group ARK'ALL we looked for another way; to do this, we sought to bring together researchers who had sensed the need to think differently. It is this tendency, this effort which will make the cement which will bind them and stabilize their bringing together in the same group.

The field which has thus been opened up is so vast that it is impossible to write everything down. It is above all necessary to make aware of those who want to get out of traditional knowledge and circles that they can and must attempt a breakaway, a jump, and above all that they are not, that they are no longer alone.

ARK'ALL then the DECALUM association and the EUREK'ALL Company have placed ideas in these courses which will spread among the peoples; these ideas will get people used to accepting what may seem strange. We will have to take the following attitude: if a fact seems unacceptable, rather than hiding it or rejecting it, we have to change our reasoning.

Through this new discipline of thought, facts that have been rejected or distorted - because they are incompatible with the Cartesian system of thought - are immersed in the same bath and become understandable.

Arkalian research applies, in its approach, to reinjecting the methods of the approach. This is very important and must be meditated on because, in this way, the search for it is in the working environment which reflects the spirit which it has adopted. It "is being".

Finally, it is desirable that readers who will necessarily be faced with new words or known words but used in a totally different sense, do not begin to distort what they are supposed to mean here. These major drawbacks tend to

to bring the reader back to what he knows or even to ensure that he appropriates new terms in order to use them in contexts which destroy them instead of enhancing them - this last attitude obviously corresponds to dishonesty There is also those who misinterpret concepts.

“Now if you have understood (the Philosopher tells us) you do  
n't need my explanations any more... and if you haven't  
understood, it's because you'll never understand. »\*

Jacques Breyer

This thought concludes Jacques Breyer's book “Terre Omega”[5]. Jacques Breyer worked for nearly forty years. He was part of the team which, at the Château d'Arginy - near Mâcon - from 1947 to 1952, tried to revive the Templar Order and achieved very spectacular results in the octagonal Tower known as the Tower of the Beatitudes, as much day, inside, as night outside.

Note : we must deplore the terms improperly used, especially in the field of forms.

The words "magnetic" and "electric" chosen by Bélizal and others, lead to confusion with the real electric and magnetic words of physicists; they could, without damage, be replaced by others. This is the reason why we took E for electric and M for magnetic, avoiding pronouncing the two words but simply pronouncing the letters E and M.

It is the same for the aura which intervenes in the diagram of the vital field. It is not the aura seen around the human body. This word was established by analogy - in the rational sense of the term - of the aura of the human body.

Exercise :

- 1) Check that in multiple places where there are electrical equipment - household appliances, TV, sound systems, amplifiers, electrical installations under plaster, sockets flush with the walls, etc. ; we find a state | QTL > - QTL in Hebrew means to kill, murder, slaughter [i] -.
- 2) Check that QTL - the word - corresponds on the disc or on the emitting square to an eif close to RE.

a) First build a barrel 19, 9, 12. To avoid orientation place a small nail in the groove separating segments 9 and 12.

b) Hold in the hand by segment 12. It thus leaves this eif which one finds on the transmitting square (or on the transmitting disc).

- 3) In general this eif does not have this state | QTL>; check it.

**Mistake! Bookmark not set.**

- 4) Check that the state | QTL > is the same as state | K Sh R >.

**Mistake !** means: to accuse someone, to hold a grudge, to bind, to tie, to complete, to conjure against, to be tight, to be robust, to be strong (here the point on the Sh is on the right; naturally as it has been pointed out in the course of the 1<sup>st</sup> level the point on the Sh is either to the right or to the left but never in the middle; on the other hand, to detect in the domain of forms it must be moved to the middle).

- 5) Check that a barrel 19,21,22 with a small nail planted in the groove of the 21,22 and held by the 22 emits the same eif as before.

**Mistake! Bookmark not set.**

- 6) In general this eif does not have the state | K Sh R >.

Note : J. de la Foÿe remarks [ii] that a farmer he knew had asked him to locate underground water passages in his orchards in order to avoid building the house he was considering over them. Let us immediately point out that houses can be built above such places, but then we must take into account the shape of the house and also think that this shape must be sufficient to block any harmfulness after the people who will move into the house can furnish it according to their aspirations without modifying the balance obtained. This can easily be done by people like Serge Henneman, Philippe Arnault, Bernard Menguy from the ARKOLOGIE <sup>1</sup> Association and by people like Luc Labat and Sophie Nouvel from the BARKA Company. On the other hand, you have to be careful with certain people who call themselves geobiologists because geobiology, very often, does not allow you to work in such a subtle way as people from ARKOLOGY or BARKA. Geobiology seeks too much inspiration from rational methods and their approach and way of thinking are very Cartesian and are inspired by the usual models.

J. \_ de la Foÿe, about the request of this farmer, did not detect anything, on the surface, harmful for the vegetation. The house was built; it didn't change anything. But on a narrow strip of land, at the end of a beet field, the grass surrounding the house had become like a desert.

First approach to the neutral pendulum: we felt a harmfulness.

Then the state  $|QTL\rangle$  was detected with the appropriate pendulum.

This state could be detected from a recently planted EDF pole; fitted with an earthed lightning arrester to an old hay rack with parallel bars left about a hundred meters from the post.

The rack, at the request of Jean de la Foÿe, was removed. After a few weeks the grass and the beet leaves started to grow.

**Mistake! Bookmark not set.**

Conclusion : States were found  $|QTL\rangle$  or  $|K\rangle$  Sh  $R\rangle$  in others places of other places; for example :

- between a flour mill motor and a television antenna.
- between a manure removal motor and the ground connection of another appliance.
- between a cast iron stove and a gutter. <sup>1 2</sup>

<sup>1</sup> Association ARKOLOGIE, 77 rue de la République, 93200 Saint-Denis

<sup>2</sup> BARKA Architecture, 31330 Launac

- between two bedside tables on either side of a bed.

The latter case occurs quite rarely.

Exercise : We build a wooden or cardboard disc - striped on one side, smooth on the other -.

The free face is placed against the plane of a table - without a drawer - and not above a foot.

- 1) Check that LYLH is detected above and h AWR on the unscratched part.
- 2) Check that LYLH is detected at the tips. 4L

3) Check that a grooved board like 5 12 10 12 opposite emits LYLH on the side of 5. For this, we plant a nail between 10 and 12.

- 4) Check that at LYLH there corresponds an eif close to the UVÎE located at  $60^\circ$ , in reality the eif is detected at  $V^+M$  on the transmitter plate, when the needle is very close to  $59^\circ$ .

- 5) Check that if we have the eif LYLH in a giver

undifferentiated or differentiated spectra this

- 6) Make assembly <sup>3</sup>[iii] and observe that the

indicated color does not come out at  $V^+M$

$V \setminus$

<sup>3</sup> Jean de la Foÿe points out [2] that often the best mood balancer is powerless before the  $|QTL\rangle$ .

### *H.     Overlap: Experience and Energy*

Consider two types of crystals: quartz and obsidian. They will appear in the form of shapeless blocks: the first constitutes an F shape and the second an F' shape.

Let's place the block of quartz F on the block of obsidian F'.

1) Verify that new eifs appear <sup>4</sup>.

Note : We will call such an assembly a overlap. But it may happen that:

- 2 shapes F and F' will absolutely not be in this position and one will overlap the other.
- That 2 forms F and F' are such that F overlaps F' but F' overlaps F - we are outside the usual representations, we must not forget -.
- A human being can be ridden by another human being; it happens ; or by an entity; or by a group of human beings, or by an animal, or an element of the vegetable kingdom, or any other form; even by place.
- There are overlaps in Voodoo. Here the human beings are overlapped by snake-like entities but many others are possible because their number exceeds 800 .

snake entity;

what will be called later: the Enel attached to the serpent.

In the Voodoo cult overlaps are sought. The human being,

when ridden, should not be seen - as a form - as a

human being. It is our tendency to localize in the field of rational coherence ( rational or usual C. de C.) which makes us return to the localized form.

- Notation: F' overlapped by F will be written: F' <sup>F</sup>

2) Use the previous montage, ie F' <sup>F</sup> to soak up the concept of overlap.

Tips :

<sup>4</sup> This is because it was assumed that the undifferentiated and differentiated EFF spectra do not constitute all possible eifs.

- Care must be taken when working with forms not to be overlapped by either a form, a set of forms, a state, a being etc. For example, a very big fear can create an overlap.
- When working on a form and it is difficult to detect the eifs of a form, its states, one must ask oneself if the form is not overlapped. If this is the case, it is necessary to think this form overlapped and completely detach from the usual representation.

3) One can also find overlaps between numbers. That's what had

approached Georges Barbarin [iv] who had proposed  $1, 1, \dots N$  where  $N$  and  $P$  are positive integers. He thus spoke of rider number and horse number.

A number overlapped by another does not give a number. The hypothesis presented in the work of Vladimir Rosgnilk [v] is perhaps not the correct one; indeed we had supposed that to  $N^P$  corresponded what we called a Cumulo-Decalar Arithmetic <sup>5</sup>. But this hypothesis will not be accepted for the moment <sup>6</sup>.

4) It can happen, when testing human beings, that a person is overlapped and

than a state, for example like

**Mistake! Bookmark not set. Mistake! Bookmark not set.**

| K Sh Ph with reversed Sh > be placed

on this new form - the person being ridden -. We thus arrive at states that are very polluting and difficult to annihilate.

<sup>5</sup> These expressions will be presented later in the course.

<sup>6</sup> Naturally the writing  $a^b$  used in mathematics where  $a$  and  $b$  are numbers absolutely does not correspond to an overlap.

## Chapter III

### Taofel fields

Obsidian (one block) overlapped by quartz <sup>7</sup><sup>8</sup> (one block) led us to discover new eifs. They are called Champs de Taofel.

We were able to classify them.

But whereas in the case of the EFF eifs there was no ambiguity, here we are faced with an instability which attaches to the concept of Taofel Field. The very concept is not stable, it leaks.

In this domain of forms, like the flight of landmarks - which we evoked at level 1 - the flight of concepts will often occur. This does not bring an impoverishing indeterminacy but on the contrary an immense richness emerges from these concepts and landmarks in flight, wandering.

We discovered the Taofel fields by operating a device invented by two researchers Léon and Marie-Thérèse Sprink.

Thus the first two Taofel Fields (C. de T.) were felt.

They had also been discovered by two other researchers who worked on the shapes, Lucien Chaisemartin and Morel, shortly after the Second World War. They were the ones who had completed the so-called “fictitious cone” pendulum and some of these pendulums, at least the first series that was put on sale included 2 graduations supposed to correspond to the first two C. de T..

They called them "vertical emissions", the others of the EFF level being called "horizontal emissions". We are going to extend our research to these famous C. de T. and to do so, study in detail the work of Léon and Marie-Thérèse Sprink.

<sup>7</sup> These are not obsidian and quartz entities.

<sup>8</sup> Taofel field: abbreviation C. de T.

## **SHAPES AND ELECTRIC FIELDS**

### **Leon and Marie Therese Sprink**

Léon Sprink was born in Russia at the end of the 19<sup>th</sup> century, he died in France in 1967. He is buried in the Russian cemetery of Sainte-Geneviève-des-Bois. His family was of Baltic origin. Very young, he was very imaginative and curious about what interested him; it is necessary to announce the observation which it made of a solar eclipse whereas it was in a field belonging to a family property, rather particular eclipse, the solar plasma had been put in the form of cross of Saint Andrew. His father, before the war of 1914-1918 took him to visit the beer factories of Moscow. The beer obtained in these factories was of rather poor quality and the fermentation of the hops required too much time, according to the technicians present. They had no remedy to decrease the fermentation time and increase the quality. The young Sprink, having returned home, asked his father for permission to work on the fermentation of beer. His father gave him the elements and he imagined (he must have been about 16 to 17 years old) forms of fermentation tanks as well as the alloy which was to compose them.

His process was applied and the quality of the beer was singularly increased as well as the speed of fermentation of the hops. But during the revolution, in 1917, the crowd entered the factories and smashed these vats with sledgehammers..

Anyway, even if the tricks imagined by the young Sprink were lost (we could find equivalent ones now), the beers made in our time are quite good and the fermentation speeds sufficient not to pose the problem again (note that some beers now contain dyes and other chemicals and it would still be better to process them by a Sprinkle type process, this would further enhance their taste and make it a very healthy drink). The Russian Revolution did not spare the Sprinks. He was locked up in the “Peter and Paul” prison in Saint Petersburg. There he was tortured. (He has moreover, in this prison, witnessed the agony of a very famous Pope from Russia). It should be noted that he was one of the rare survivors of this prison; indeed there were only 3 or 4 people who were not murdered there. He arrived in France and was declared 99% disabled.

He met shortly after a young widow, Marie-Thérèse Roussel with whom he married. She died in 1951 of cancer. She was remarkably intelligent and they began their research <sup>work</sup>.

In 1923 L. Sprink was in Strasbourg, in a chemical industry factory: a stearin factory. He was the owner of a process for manufacturing soaps with high detergent power that the factory in question had adopted. There was a research laboratory, modest indeed, but the factory was at his disposal for industrial checks.

The results of the application of these soaps, especially in the raw wool washing factories (in Alsace and in the North of France) were more than satisfactory.

But now, after two years, there were declines and irregularities in performance. First of all, the cause was sought in the difficulties specific to the industrial scale-up of a process established in the laboratory. Time was wasted verifying the process itself as well as its theoretical bases.

This factory still had a boss, born in this factory and master at home. One day he reproached L. Sprink for “looking too much from noon to two o'clock” and he added “You know, the manufacturing recipes only last for a short time, without there being any need to modify them”.

There we recognize, in this reflection, the point of view of the industrialist who is always in too much of a hurry and too lacking in solid bases for understanding the mechanisms. It is the contribution of research laboratories (in basic research) that then becomes valuable.

It therefore emerged from this interview that the manufacturing process as such was perhaps not the cause of these yield disturbances. We had to look elsewhere.

At the time, the manufacture of soap in this factory was too recent to establish a scale of comparison of the presumed variations. On the other hand it was not the chemical analyzes of its composition that could provide information. There was in the end

<sup>9</sup> *What* relates to the life of L. Sprink and his wife as well as their attempts has been reported in the notes of the couple as well as their "logbook" which they kept very well throughout their career of researchers. We will not discuss here in detail the scientific personalities they have touched to make known and share their work. Their steps would be the subject of a volume - hopes and disappointments followed one another as for all these researchers who worked in non-Orthodox fields -. Let us nevertheless mention the meeting of L. Sprink and A. Einstein which took place in Germany before the departure of the latter from this country. This meeting was memorable: it lasted an afternoon. Einstein proposed to the Sprinks to go to the USA where he was already thinking of going. The Sprinks during the 39-45 war remained in France and worked near Grenoble). Einstein gave Sprink his thoughts on his work. It can be summed up as follows: “I work by breaking down and you (L. Sprink), you work by assembling”. Einstein had really seen Sprink's approach and that is what is essential because in this area the approach is different from the usual approach.

than the results obtained from users. There, we knew that the soap was more or less good; therefore variable in quality.

This soap was made with fatty acids produced at the factory. L. and MT Sprink therefore began by studying the results of laboratory control of these products. Immediately, they were presented with the averages per month and per year, as well as the figures for the output of the factory. The averages per month, taken step by step, were not very clear; on the other hand, the averages per year turned out to be much stronger for certain periods with a decline before and after. This was especially striking for the years 1911 and 1912.

#### Autoclave study :

The first processing operation in a stearin factory is saponification: decomposition of triglycerols into glycerine and fatty acid. In the factory in question, this operation was done with autoclaves, under a constant pressure of  $10 \text{ kg/cm}^2$  with direct heating at  $180^\circ$  by steam. It was done in two stages:

- Five hours under pressure - a rest - change of water (otherwise, the concentration of these waters in glycerin would have slowed down the reaction), a rest of twelve hours and a
- pressurization for three hours.

This walking pace, found empirically, gave very good results at the time. After the first five hours of walking and at the end of the operation, the results were checked in the laboratory. As there were four autoclaves in operation every day, there were 16 index determinations per day. This made it possible to group the saponification indices and the acid indices by four, which initially avoided excessive differences, due to anomalies which could occur from fortuitous causes. It is for this reason, and also because saponification was closely dependent on the yields of subsequent manufacturing operations, that the Sprinks subjected these data to close study.

Immediately, they had to realize that with the system of averages per month, there was nothing to do.

Faced with this semi-failure, they fell back on statistical methods, while maintaining a certain mistrust of them.

The construction of frequency curves of a discrete numerical series, which gives the number of cases for a given result, obviously provided them with dispersion curves of the results (Gauss bell curve).

But the Sprinks have therefore attached themselves to a statistical law to deduce results to be exploited. It should be noted that their apparatus did not function entirely in a rational way and that the view advocated by M. Beigbéder [vi]: a statistic depends on the mode of reasoning chosen and the statistics used until now are within the scope of usual coherence, was not known to them - M. Beigbéder's book coming out in 1977 But L. Sprink was sensitive enough to feel well:

- that his device was not quite a technical object and
- the fragility of the use of statistics on the progress of his device.

On the other hand, he had to have industrialists accept his results as well as his manuscript at the Academy of Sciences <sup>10</sup>. On the other hand, we can apply a statistical law to the phenomena studied by the Sprinks, in particular to saponification in a stearin factory. This digression was necessary to show the caution with which these phenomena must be approached and to know the field of coherence in which one must place oneself.

The first surprise of L. Sprink and his wife was to note that, in spite of a statistical average (the most frequent value) and which was by no means what they considered important (which was the considerably lower arithmetic mean) there had on each curve not just one, but two or three characterized maxima. But what astonished them even more, it was the observation, absolutely unexpected, that from month to month, there was like a coming and going of the location of these maxima. In other words, from a statistical point of view, the reaction fluctuated more or less widely depending on the time of year. It was then that the idea came to them to lay out the daily results in the form of a curve, where the ordinates were brought in proportion to their numerical value and they finally saw a certain periodicity appear.

Obviously, we knew “by experience” that, for example, the yields of autoclaves varied with the seasons and that yields were better in winter than in summer. We even found for all these irregularities a perfectly plausible explanation by the low winter temperature - autoclaves obviously cool much more than in summer, so there is more steam entering an autoclave in winter than in summer - and where a greater agitation of the materials in reaction and a greater dilution of the glycerinous waters. However, this explanation does not correspond to the real state of the conditions. However, as often happens in similar cases, this had prevented further research.

<sup>10</sup> L. Sprink deposited at the Academy of Sciences a manuscript composed of 2 parts. The first was only descriptive and the second an attempt at a theoretical approach involving conformal transformations and propagation results of an electromagnetic field.

To begin with, a quick harmonic analysis revealed a period that corresponds to the 28 days of the lunar period. Under these conditions, grouping the results by month obviously could not give anything very clear.

The simple fact that the two consecutive maxima were in reverse order in spring and autumn demonstrated to the Sprinks that their autoclave-related curves followed the rhythm of the tides. But to neutralize the tides, there is no way!

There was still an anomaly that put them on the right track. It has just been said that autoclaves generally function better at the winter solstice than at the summer solstice. However, the tidal indices are the same at these two times of the year. It was therefore necessary to find one more variable which was periodic and this period had to be the same as that of the operation of the autoclaves. Among the curves drawn up by them, there was one which related the results obtained from the autoclaves and the hours of their pressurization. The results followed the curve of variations in the earth's electric field. It is known that the field is relatively more intense in winter, in dry and cold weather, and is therefore much more stable than in summer.

This last observation left them very hesitant for a long time.

An autoclave being a completely closed container with walls approximately 50 mm thick in pure copper, it is therefore a Faraday cage. The Sprinks still wondered if it was not another phenomenon that was alone, the real responsible.

Fortunately, they were able to consult the original publications about the Faraday cage. This is very interesting because going back to the sources of the works one finds detailed experiments and also the reflections of their authors. Publications and works were still, fifty years ago, much richer in detail. The “academic” style presentation that we now find makes researchers believe they are working on solid concepts, and even some do not know the reason for certain hypotheses. A hypothesis, an axiom, are often an admission of ignorance and their role is to bring together various intuitions. Knowing these intuitions, bringing them out and immersing them in the middle of your personal thoughts allows you to give them new life; and also makes it possible to pinpoint the weakness of certain theories, or to feel other approaches. The machines built in the 19th century have for some, come very close to the delocalization of their functionalities; this is how Tesla even in the twentieth century was able to obtain rather curious effects. He had observed electrical actions which appeared to him outside the usual laws. If we consider electric motors, there were more than a thousand models made by multiple inventors

and very few have been preserved (like the one called "in a squirrel cage"). People had imagined odd windings, and then in this case, at the level of the axis of rotation can appear shifts or channel and emissions with high Taofel fields.

The search for localized principles has resulted in the unorthodox cases being dismissed or forgotten. As it was believed that only the principles attached to localization (the concept of localization and flight of reference marks being ignored) were the only ones making it possible to describe the universe, technical objects were made according to them and other objects which were not of the class of technical objects, have disappeared or have remained memories of no interest.

By consulting Faraday's original publications, the Sprinks realized that, as the author himself pointed out: the Faraday cage is valid only for electric charges in equilibrium.

In an autoclave, heated by steam, this is not the case because there is a continual supply of electrical charges. They had conclusive proof of this by removing these fillers inside the autoclave, which greatly reduced the degree of saponification.

They therefore placed the autoclaves in an electrostatic field in such a way that its value was large enough to neutralize as far as possible the variations of the earth's field and so that the values which appeared to be values could be exceeded. "threshold" for high efficiency.

The success was overwhelming and spectacular (it happened in 1933-34). After a few months, with the new regime, it was possible for them to draw some provisional conclusions.

- 1) From the point of view of the quality of the goods there was a notable progress. The saponification and acid indices were higher than with the old step and joined the saponification indices of fats and oils when they were loaded into the autoclaves. This drop in the indices at the exit of the autoclaves was intriguing, it is mainly for this that the Sprinks had made spectroscopic measurements before and after the passage of the material in the autoclaves and had demonstrated that it was due to chemical condensations of the fatty acids and oxidations. Removing these reactions gave them a clearer commodity but more importantly a less acidic pH. Their products thus benefited from a new application: cold paving. On the other hand, the fatty acids now crystallized much better than before, which, in a short time, increased the yield at the presses (hot presses) and considerably increased the production capacity of the factory in which they were experimenting. .

The amplitude of the variations qualified as lunar by their care was considerably reduced. On the other hand, for the annual curve, it was less clear.

2) The autoclaves: for the autoclaves, they obviously adopted a different course from that before the tests. We will not develop their method; it would lead to too technical details.

They continued their work. Mrs. Sprink studied the formation of cements at low temperatures. She had arrived at a very fine process for making ammonia. Unfortunately, this process required furnaces of a special model that the industry could not afford to build, especially at the time of the great industrial crisis of the 1930s, which had seriously affected the cement industry. 30, which had seriously affected the cement industry.

They therefore thought that the difficulty could be circumvented and obtain a massive saving of fuel by using the installations which L. Sprink had just applied to the autoclaves.

He had two reasons that encouraged them to try the experiment:

- 1) the decarbonation of limestone is from the same group of reactions as the saponification of fatty substances,
- 2) L. Sprink had observed a very strong increase in temperature in the autoclaves. Very troublesome to autoclaves, since it hindered the circulation of steam, this exotherm represented an enormous advantage for ovens.

This increase in exotherm had initially left them perplexed. It may seem that the energy conservation principle of an oven is only 20-25% of the energy supplied. It could therefore be admitted that quite simply the efficiency of the oven had been increased. This is the explanation they adopted. It doesn't really explain anything, but at least it was found satisfying for the mind. This is often the case in research where an explanation that is not correct but reassures the mind, allows the researcher to stay on "the beaten track". Fortunately Sprink had fully sensed the danger of such an attitude.

This "exothermy" remained variable, as did the yields and results at the stearinage. It even seemed that the deviations from the new average had increased. So it was clear that an additional factor they didn't know was at play. But it was certainly not the terrestrial electric field nor the lunar tides.

Previously we saw that these same variations had also manifested themselves in autoclaves but in a much less clear-cut way and moreover not very inconvenient for the application of the new process in the fatty substances industry, the desired goal having been achieved.

Such would not have been the situation in the cement industry. Indeed the qualities of the cements, in their kiln, and especially the resistance were very variable and followed inverse curves of the fuel consumption.

Thanks to some observational data, few in number, but which could not be considered as fortuitous coincidences, and discarded for this reason, the Sprinks arrived at the quasi-conviction that these disturbances depended on solar activity, which had become more apparent by the suppression of lunar effects of much shorter period. This last result can obviously be obtained by harmonic analysis, thus demonstrating the existence of these longer periods. But at that time, harmonic analysis had a very great defect: it eliminated all accidents. But they had only those to guide themselves! Based on certain observations of the solar corona, they quickly realized that this was where the solution of the problem that fascinated them would come from.

Until the 1939-1945 war, the solar corona could only be observed during solar eclipses. Since then, observations have been made as regular as possible but of a still insufficient duration (covering two to three solar periods) for them to be able even in 1950 (these studies were carried out since that date but the Sprinks had thought about it for a long time) to bring to their studies decisive elements. (It should be noted that the Lyot corograph only dates from 1937).

They were able to see that the best returns in the industry occurred 3-4 years after peak internal activity. This excluded the influence of sunspots in either direction.

It has long been known that the appearance of the solar corona changes during a period of solar activity. Very intense at the time of maximum solar activity, it is then evenly distributed around the sun and especially at its poles. At least it is very developed in the direction close to the equator. In the intermediate periods, its form is intermediate. At certain times, it has the shape of a cross of Saint-André. And we will focus particularly on such times.

We are here faced with a form which presents itself in a certain way to the observer; it will obviously not be the same for all observers (example: an observer in space in a direction at  $90^\circ$  from the earth-sun line). So the eifs

detected will not be the same. Objectivity and subjectivity here disappear. It is enough to make a simple experiment to be convinced some: if one considers a horizontal magnetic field and that one puts in this magnetic field produced by 2 cylindrical magnetic bars a cross of Saint-André, one will observe certain eifs. If we rotate this cross of Saint-André by  $45^\circ$ , we will observe other eifs. But if the observer turns  $45^\circ$ , instead of turning the cross of Saint-André, all the equipment remaining fixed, he will not find the eifs of the Croix de Saint-André.

The registration is here relative to the horizontal for example.

In the case of the sun, it is relative to the line passing through the observer and the center of the sun. We therefore have correct identification and no ambiguity on the observed cross.

When we talk about the cross of Saint Andrew, without attaching ourselves to an apparatus with which it can be associated, it is because we tacitly assume the notion of horizontal in relation to which it is placed. And in this area of the eifs. - C. de T. and associated states This tacit knowledge must always be taken into account.

Let us recall that L. Sprink, child, in Russia, walking on the lands of the paternal properties had had the chance to contemplate, during an eclipse of the sun, the solar corona but presenting itself in the form of a cross of Saint- Andrew.

It was therefore, as we have already indicated, shortly before the war of 1914 and this in conditions of extraordinary visibility. He drew from this memory the image of two crossed discharges between four points, and being made between the diagonals of the square joining the points.

HT (Naturally the tips are assumed to be placed so as to distribute the correct symmetry) <sup>11</sup> In electrostatics, 'x' "z" on

learns that in this case, without going into details the 7k discharge is done along 2 sides of the square AB and CD.

<sup>11</sup> It was Marie-Thérèse Sprink who reminded him of this.

Course

2<sup>th</sup> level

Paper 12

December 97

## 2 ) Dynamic duality

Let us consider 2 shapes A and B and the shape constituted by a segment MN of middle O. In

M and N are placed two legs. Moreover let us draw a circle of center O, of radius  $OM = ON$  - circle which is only an intermediary of construction, it will then be erased Let us draw the diameters at respectively  $30^\circ$ ,  $60^\circ$ ,  $90^\circ$  of MN.

If such a shape is detected between A and B, A and B

We will see during the study of the Ying-Yang, the heuristic approach of the Dd.

We will write that A and B are in Dd by AI ---1 B.

We will carry on a cylindrical pendulum the form which makes it possible to detect the Dd.

## 3 ) Numbers crossed out

Consider a shape A and its image A' in a plane mirror P

P

In

H  
A

HA physics A' is said to be the image of A by the plane  
S'

Let  $A' = \text{Imp}A$

So let's now consider the process we put in place in the course of

1<sup>st</sup> level:  $A \longrightarrow \text{Imp}A$  ; so we set up a path; let's apply this way to whole numbers 1, 2, 3...

Thus  $N \longrightarrow$ ; this will give N so let's write it and call these new elements "Numbers barred". We cannot compose between them for the moment, the numbers crossed out.

#### 4 ) The fields of Taofel (C. de T.)

We have therefore listed the C. de T..

Thus we find  $1 I \text{ ----} 1 \quad 1$

$2 \quad I \text{ ---} 1 \sim 2$

$3 \quad I \text{ ---} 1 \quad T$

then  $\sim 4 \quad 1 \text{ ---} \text{ ---} 1 \sim 4$

$T \quad i \text{ ---} \text{ ---} 1 T$

$"6 \quad 1 \text{ ---} \text{ ---} 1 \sim 6$

$\sim i \quad 1 \text{ ---} \text{ ---} 1 \sim i$

$V_i \text{ ---} \text{ ---} 1 \quad n \text{ (n from 8 to 24)}$

$"2? \quad 1 \text{ ---} \text{ ----} 1 \sim 25$

$\sim 26 \quad 1 \text{ ---} \text{ ----} 1 \sim 26$

$\sim TI \quad 1 \text{ ---} \text{ ----} 1 \sim 27$

But the notion of Taofel Field is not stable; sometimes we will detect  $28 \quad I \quad 1 \quad 28$  , or

we will not detect any such thing, other times we will not be able to predict anything

after  $26 \quad I \text{ -----} 1 \quad 26$  . We say that this notion of C. of T. is unstable. She flees.

Thus, we will designate this escape by where co is the infinity sign used in mathematics.

The C. de T. are eifs; their leak oo  $I \text{ -----} 1$  co also.

#### 5 ) Consequences

The eifs, those who placed themselves in the class named EFF, were enlarged by those of the class C. of T. and their flight. And all this - as we pointed out in

the 1st level course - because we have not implicitly assumed that the discrete, continuous, E and M spectra do not contain all the eifs.

As we had not imposed any restrictions, during the experiments - types of overlapping shapes, Sprink apparatus and other assemblies - other eifs were put in place which proved to possess interesting properties.

Especially for the benefit of living beings, the C. of T. are superior to some eifs of the EFF class. And their escape is even better. One can therefore place in dwellings forms generating these eifs with high C. de T. and even their escape.

About a Sprink device, with 50 kV of voltage and 1 mA, we get both

first C. of T. i.e.

1 I -----1 1

2 I -----1 T

We have made such a device. If the tension increases, one passes to higher C. of T..

It was possible to use 120 kV and 1 mA, this makes it possible to pass to 3 I 1 3 .

With 180 kV and 50 jiA - almost no current is needed - Léon and Marie-Thérèse

Sprink must have gone up to 6 I -----1 6 and even 7 I -----1 7.

Projects are planned at much higher voltages, which requires very large frames so as not to have flashes and only remain with effluvia.

At the point of intersection of the straight lines joining the diagonal points of the spark gaps, a shift is detected when the device is energized, which means that a leak from the markers occurs. Thus approaching this point, the usual physics is no longer usable; it is necessary to use the physics known as “Unstable Benchmarks”.

“Our wishes are the presentiments of the faculties which  
lie within us, harbingers of what we  
will be in a fulfilled state. »

Johan Wolfgang Goethe

born in Frankfurt am Maine. 1749-1832?

Goethe is among the powerful figures of the West. By the extent and variety of his knowledge, by his gifts as a poet, novelist, playwright, critic, scholar and even administrator, he is in line with the great men of the Renaissance. He always submitted to the laws of Nature applied to the sensible world, without however neglecting these mysterious forces which he classified under the name of “demonic”.

He deserved this eulogy from Napoleon, after their interview at Erfurt: “Here is a man”!

We also owe him his theory of colors and a spectrum that is not that of Newton. We see magenta appear in this spectrum of Goethe which Goethe himself called "peach blossom color".

It was discovered by J. Ravatin an eif, the “Creative Word” (VC) which is precisely emitted by peach blossoms and by the color magenta.

Note that most acrylic paints sold on the market with the mention “magenta” do not emit VC.

From the therapeutic point of view it is ingenious to use the two spectra simultaneously, Newton's and Goethe's.

Exercise : We consider a bottle of Champagne that we fill about 1/4 or 1/3 of its height with coarse salt.

1) We don't stop it

Check that it emits 2 I -----1 2

3 I -----1 3

2) Place a cap

Check that it no longer emits anything.

3) We put it in the ground: we plant in it a stem of copper

or elderberry, which

touches the salt and comes out of the ground.

Check that C. de T. is no longer detected but that above the stem

V'M and VÎM- ARE detected

4) We take 2 such bottles of Champagne all containing salt

as before and place them in the ground. They are connected by an

Check that 3 I -----1 3 is detected

~4 I -----1 ~4

$T_{i-iy}$

ËF I -----1 ËF for Nfrom 6 to 22.

5) Check that with even bigger bottles it works the same way.

6) If, on the contrary, we try the experiment with small diameter bottles, it works less well or even does not work at all.

## SHAPES AND ELECTRIC FIELDS - Léon and Marie-Thérèse Sprink

(continuation of the 2nd <sup>booklet</sup>)

It is especially on the instances of MT Sprink who relies as much on his intuitions as on his knowledge, that they themselves realized a device inspired by this remark - The eclipse of the sun of 1913 seen by Léon Sprink in Russia-..

It consisted of four electrodes, arranged around a circumference and connected to a stable high voltage electrical source; however, the results have proved to be incredibly violent and often contrary to the desired result. They called it their "little sun". It was quite by chance that they were able to realize that the phenomenon they observed was very similar to those caused by the activity of the sun. It was MT Sprink who had the joy of seeing it; it was the unforeseen occasion, and for good reason, of the aurora borealis on the night of January 25, 1938.

This aurora borealis covered all of Europe. She was a grand beauty. It has been seen in France but also in almost all European countries, as far as Portugal, northern Italy, Greece, and with exceptional intensity. In France, the Jura, the north of the country, the western provinces, Normandy, Anjou have been particularly favored by this majestic phenomenon, so rare in our regions, and as far as Provence where the astronomer of Kerolya saw her in Forcalquier.s

Gabrielle Camille Flammarion wrote an article in the illustration [1], We reproduce her description of the phenomenon.

"However, more than two hours after sunset, the clouds are breaking up. Around 6:30 p.m. the northern horizon lights up, as if the day was about to be reborn. It is a nocturnal dawn whose light comes from the North. A blue-greenish glow invades the north and travels northwest. Gradually, the northern horizon flares up. A kind of purple cloud appears in the northeast and moves towards the northwest. It folds up, undulates, expands, dies out, revives, while immense jets, whose color changes from blood-red to orange-red and yellow, soar towards the zenith. The apotheosis occurred around 7.50 p.m. A magnetic disturbance was recorded by Perrotez, at Juvisy: it began on the 26th at 3 a.m.; the violence was such that the light spot left the field of the recording paper for more than an hour". It is even reported that this aurora was seen, even further south of Europe, from a ship passing off the coast of the Rio de Oro, that is to say at a latitude of 28° [2], "When the sun reappeared, there was nothing abnormal, apparently on its surface <sup>1</sup>. However, a round spot, of a particularly intense blackness had just passed through the central meridian of the star". By testing the phenomenon, we find that there was appearance of a shift. There were the issues of the first 4 C. de T..

On the other hand, a sunspot corresponds to a decalar. Some may be anti-decals but they are not channels. There are no emissions at high C. de T. from these spots.

The decalar associated with the aurora borealis is not necessarily that of a sunspot. The aurora borealis is not associated with a decalar in general, nor with emissions at high C. de T..

There was a very interesting effect reported by L. and MT Sprink while working with their device. Their device was placed near a heating boiler; during the aurora borealis the boiler had its water boiling although the air inlet shut off worked perfectly. The next day, L. Sprink learned that several central heating boilers had been damaged and that chimneys had burst in the city where he was. In 1949, he spoke about it to Cotton <sup>1 2</sup>. Cotton sends him a little-known text by Buffon on observations relating to blast furnaces.

In the 18th century, the aurora borealis were frequent over France and the masterful observations reported by Buffon are in all respects equivalent to those observed by L. Sprink ·

L. Sprink also cites Weyprocht's observations of the aurora borealis during Tegetheff's expedition to François-Joseph Land. It was observed, during this expedition, that during certain very mobile aurora borealis, the magnetic needle moved towards the east, that the horizontal component decreased and that the vertical intensity increased! However, this is what L. and MT Sprink were able to verify on their device in January 1938 (except for the horizontal component of the earth's magnetic field because they

<sup>1</sup> This documentation was provided by Jean-François Boédec.

<sup>2</sup> Mr and Mrs Cotton have produced a precision balance that bears their name.

did not have a suitable device). The Sprinks had concluded that the field emitted by their device was identical to that emitted at the time of the aurora borealis phenomenon.

In reality, in the case of that of January 1938, we can see that there was the C. de T. which came out of the Sprink assembly but that there were 3 others in addition. On the other hand, the Sprink device makes it possible to obtain a

decalaire. L. Sprink also points out that at the observatory of Arosa, it has been observed that the "clear nights" return periodically and always after the maxima and before the minima of solar activity. We have not checked whether this luminescence of the night sky is interpretable in the same way as the aurora borealis, ie whether there is a shift and emissions at high C. de T.. It should be remembered that all the aurora borealis do not have the characteristics of that of 1938 [3],

Let us point out a curious observation which occurred in 1913 [4]. She was observed from a boat on January 21, 1913<sup>3</sup>. This is a square halo around the moon. The color of the halo was yellowish. It looked

e was about 3 times the diameter of the moon.

This was not known to the Sprinks, but it is interesting to cite this unusual figure and also to notice this position of the square halo which is found somewhat in this form in one of the assemblies used by the Sprinks<sup>4</sup>.

They actually made a square frame put in the position below. This frame was placed on a support. In the middle of the sides of the square and perpendicularly were fixed electrodes which made a cross of Saint Andrew with respect to the horizontal plane. There is a resemblance between the two 2 figures. If we consider the shape composed of the moon and this halo, we see that it was a shape neither testable nor untestable.

testable. There are no Taofel fields or decalaires. We see<sup>D</sup> that the programs are not the same but it is good to point out this oddity which is roughly what the Sprinks had produced in one of their montages.

Human history is full of these observations which do not seem to fall within the standards usually accepted: we can also cite that of June 15, 1965 where we saw from the deck of a boat, and it was photographed, two suns in the sky almost perfectly. The passengers were on the deck of the ship. They saw the sun and the false sun; the false sun had a little lower luminosity, its diameter was slightly smaller, it was at the same height above the horizon, that is 1°8' of arc, and its distance from the sun was 3° 36' to the left of the true sun. The phenomenon has disappeared.

If we test, we find the first 7 Taofel Fields.

The false sun emerges from a decalaire. There is no magic state of any type. Do not believe that every bizarre phenomenon has a magic state. A magic state always corresponds to an inconsistency with respect to a human being, an inconsistency due to the fact that a problem is poorly considered.

A phenomenon like a form can very well only be an emergence and then there are other impacts in the local. Emergence leads to a "trace" in the room which is confused with the phenomenon itself if it is completely localized. But if it is not completely in the local then there will be some kind of echoes of this phenomenon for localization. Sprink's work continues. It was not until 1944 that they found in a cement factory (where they were testing the device developed by them in Strasbourg before the 2nd<sup>World</sup> War) truly complete archives, including daily analyzes of continuous production. It goes without saying that this documentation was for them

<sup>3</sup> This observation was taken up in the book by William R. Courliss entitled "Hanbook of Unusual Natural Phenomena, Eds. The Source of Book Project, Glen Arm Md. 12057, USA (1977).

<sup>4</sup> The first experiments took place with a circular wooden frame and two diametrically opposed electrodes. The frame was sometimes laid horizontally.

of exceptional value. For more than forty years, neither the manufacturing methods nor the construction of the ovens in the factory in question had changed. The coal always came from the same mine; the quarries were of perfect and invariable homogeneity for more than a century as to their composition and their physical state.

They were therefore able to curve the tensile strength of cements from the years 1898 to 1939. They were greatly surprised when they realized that the exceptional maxima corresponded to the years 1911 and 1930.

In the fatty substances industry they had already been able to pinpoint the year 1911. Now they had two points of reference at their disposal, without knowing, however, whether they involved any physical phenomenon whatsoever. The interval of 18 years corresponds to the saros of astronomers. The Chaldeans already knew this period of 18 years and 11 days which approximately regulates the returns of the eclipses. It includes 223 lunations or 19 times the interval of 346.6 days which separates two passages of the sun through the lunar node.

For their research, it was of extreme importance to find by grouping, this period in natural phenomena.

Yet the periodicity of oceanic transgressions offers a typical example of this. They have their maximum every 18 years, with a secondary maximum at the half-period. Curiously, the years 1911 and 1930 are located exactly at the secondary maxima. The Sprinks also found that on these two dates the Wolfers-Wolf number for the sun was three years from its minimum. It was said above that it is very probably above all the coronary phenomena which intervene in the physicochemical balances.

The Sprinks thought that the true concordance of the solar and saros cycles can only occur every 120 years. Oceanographic observations broadly confirm this supposition, but the situation is complicated by the fact that the solar periods have no fixed datum and can vary from 9 to 15 years. It is therefore not surprising that the meetings of the moon and the sun, the latter being in a determined state, only occur in an apparently random way, but each time they occur, the manifestations of these meetings take extraordinary magnitude. The fisheries chronicles provide impressive examples of this, describing not only monster tides, but miraculous catches as well. As soon as the action of the sun was no longer in doubt, it was normal to return to the annual variations of the results obtained in the factories. It is here that the curves of the monthly averages of the resistances of cements for the periods from 1899 to 1917 have been invaluable. The choice of this period was determined for two reasons:

- 1) During this time, the laboratory premises have not been changed or remodeled and the working methods have remained the same; it was therefore reasonable to think that these factors were not involved.
- 2) This period is sufficiently long so that, on the averages, the variations due to large periods are canceled out.

For the clarity of the presentation which will follow, it is necessary to open a parenthesis. For a long time the hardening of cement had been considered either as a colloidal process or as a crystallization. Both points of view had their partisans and the theories of Le Châtelier and Michaelis shared the favors of specialists. It must be admitted that in these quarrels nationalism did not lose its rights. Admittedly, both were somewhat right. Indeed, when it sets, the cement behaves like a colloid; it is only then that crystallization, if you prefer, "devitrification" takes place. We will see later that by their behavior in the face of external conditions, cements fully justify this point of view.

To observe these behaviors, the Sprinks were well placed, having had the opportunity to study in stearinization and the variations of processes of a colloidal nature and those which depended only on crystallizations.

By superimposing a cement resistance curve on the solar actinometric curve, the Sprinks found that the two curves are inverse to each other.

After a certain number of remarks which we will pass over, the Sprinks, by reconsidering the results obtained at the stearineries, had come to the conclusion that the yields of limestone followed the same curve as the hardening of cements. In 1932, they had noticed that the curve of yields at the presses and that of the variation of the vertical component of microseismic movements (in the plain of Alsace) were identical. At the Strasbourg factory, they had even tried to reproduce these small earthquakes, without obtaining any effect. Which is normal because causing ground shaking by explosives, or other means, has nothing to do with a real

earthquake which has much more the character of a localization. In a natural earthquake, there are often eifs that appear.

A coincidence put the Sprinks on the trail of the real solution of the problem. One day, the Strasbourg factory had an extraordinary output at the presses. L. Sprink immediately telephoned the University's Institute of Geophysics to find out if there was increased microseismic activity. The answer was given to him that there was nothing! absolutely nothing... ! But the following night, he was awakened by sinister creaks and strange noises and his bed rocked. It was indeed a clearly characterized earthquake. The epicenter was in the Palitinate, near Stuttgart, where the damage was quite extensive and the church bells rang from the shaking. It was therefore concluded that there was some immediate relation between the preceding phenomena, the earthquakes and their yields at the presses. We know that the warning signs of earthquakes exist. The behavior of animals, horses, dogs, birds and others before an earthquake is well known.

About some earthquakes, we can detect eifs 4 hours to 6 hours (and even 12 hours) before the shaking occurs. These are Taofel fields. These are certainly felt by the animals. Even human beings are able to sense the earthquake. Indeed in Persia, in Armenia, in the North of the Caucasus, certain natives of these regions feel a vague uneasiness that a long experience has taught them to relate to an imminent earthquake. Animals and humans may feel the Taofel Fields but there is a feeling that is due to something else. Everything happens as if something foreign is coming into our universe and to which some people and animals are sensitive. This something is presented as an "unfolding" which allows the setting up of the usual field of coherence, which will make it possible to find the turbulences of the earth's crust, etc.

Let's open a parenthesis on the prediction of earthquakes, (naturally this will be the usual view of earthquakes). For this, consider the case of China, which has been hard hit by these disasters. It was in China that the deadliest earthquake of all time took place, that of Hushsien, in Chen-si, which killed around 820,000 people in 1956. There were many others and the one that struck Hsingtai in Ho-pei in 1966 led Prime Minister Chan-En-Lai to give seismology priority. Today, China has 10,000 professional seismologists and 100,000 amateurs working in an organization comprising 17 centers and nearly 300 regional stations. By enlisting volunteer observers (peasants, workers, teachers, telephone repairers, meteorologists, radio personnel) the Chinese wanted the ordinary citizen to be on the side of the scientist. They enjoyed trying to predict earthquakes.

At first suspicion fell on the province of Leao-ning. The specialists noted that the epicentres of the small tremors following another earthquake, that of Hsingtai, seemed to move towards the region of Leao-ning, a highly populated industrial region. In 1970 it was decided to start monitoring this province very carefully. All the existing techniques in the arsenal of seismology were implemented, starting with the study of past earthquakes and local geodesy. The geodetic study of a major fault, made from September 1973 to June 1974, showed that the surface of the ground there rose twenty times faster than in normal times and inclined towards the northwest. During the same period, a change in the local magnetic field was recorded and the tide observation stations on the coasts of Leao-tong Bay noted a rise in sea level. In 1974 there were five times more small earthquakes in Leao-ming than in previous years.

All this led the government to warn the population that a dangerous earthquake was brewing. However no one could yet say when it would take place. Other symptoms were therefore sought, for example changes in the behavior of the animals.

Two hours before the earthquakes that took place in Po-hai on July 18, 1969, a keeper of the T'ientsien Zoo noticed that the tigers were behaving strangely; he alerted seismologists to the area and signaled that a large earthquake might be approaching. In the province of SeuTch'ouan, in September 1972, a forecasting team was able to announce the outbreak of another earthquake after observing "the panic of chickens, pigs refusing to enter their piggeries, horses and sheep frantically running in all directions. For the Chinese, men in the streets and in the fields can provide valuable information, whether on the behavior of animals or on the level of groundwater. Just such symptoms were observed in Leao-ning in December 1974. In four townships, the water in the wells became muddy; bubbles burst there on the surface. Rats and mice abandoned their

holes, just like the wintering snakes that were seen to venture on the ice. An earthquake then occurred seventeen kilometers from Hai-ch'eng, leading the authorities to believe that a larger shock was preparing <sup>5</sup>.

This case is interesting because, although there may have been emissions already appearing on that date, and disappearing shortly after to reappear a few hours before the earthquake, it seems that the localization is felt well before the earthquake. .

At the beginning of February, the animals continued to behave abnormally, and the wells began to show other symptoms of disorder: twenty-two became artesian. The opposite was observed in a hot springs station: three times the outflow of water was interrupted. According to the report, the most remarkable event took place in Chaozihe commune: Yu-nan province, where water and gas wells were seen to spring from the ice like geysers.

The pace of events quickened. On February 2, a seismological station recorded a sudden drop in ground electricity; another observed that the tilt of the ground was moving towards the southwest. All of these remarks made it possible to avoid a catastrophe: on February 4, 1975 at 7:36 p.m. the earthquake of Hai-ch'eng took place, but most of the inhabitants, warned, had been able to leave their houses and the animals had also been taken out.

Other disasters that are not earthquakes have also been perceived by animals. It is well known in France that the landslide which occurred at night on the hill of Fourvière in Lyon around the 1900s was sensed by the horses which the night before did not want to enter their stables. There too, perhaps some eifs could have been felt by the animals, but something else, which is a contribution to our localized world, is felt. There is localized physics instability and gas bubbles, mud in the waters, geysers on the ice etc. are its manifestations.

Thus, all these phenomena with quite catastrophic effects seem to be only a localized view of a deeper effect because it is not localized; it's almost an attempt at localization.

To a form like the planet earth are associated many other forms which are not localized; who cannot be located. They are in a channel. But they can have localization tendencies. There are also "echoes" to the forms.

These other forms are not in our field of coherence. In the case of animals either they project another field of coherence which gives them access to another reality, or they feel the disturbance of their field of coherence. One can wonder if one is in a localization or in the disturbance of a field of coherence by another field of coherence in the case of an earthquake.

The Cartesian interpretation of these phenomena is an unfolding in the room on which causes and effects overlap. Let us mention a device known since the highest antiquity and called "wind harp" <sup>6 7</sup>

During numerous observations, we have been able to realize that the lowest sounds of these instruments precede the rain by a few days and that the highest sounds precede the rain by a few hours. As a result of these observations, special instruments called "meteorological harps" were even built. Here is the description given by a chronicle of the time, of a harp built in 1789 by Ventan, provost of Burkly, near Basel in Switzerland.

"This harp consisted of 15 iron wires 320 feet long, placed in a garden, 2 or 3 inches apart, and stretched with large cylinders. The thinnest rope was about a line thick, the strongest 6 lines. They were arranged in the direction from north to south, and inclined so as to form an angle of 20 to 30° with the horizon. When the weather changed, the harp gave out sounds so powerful that they drowned out all the noises in the house and almost inspired a feeling of terror; sometimes its tremors mimicked the rapid murmurs of boiling water; other times the distant playing of a harmonica, carillon or organ. Attempts were made to stretch these iron cords in the direction from east to west; they no longer produce any effect. » [5]

<sup>5</sup> "The UNESCO Courier, May 1976 (XXIX year).

<sup>6</sup> L. Sprink was aware of this experience and reported it in his report.

<sup>7</sup> We mention it here because we must be careful not to model the effects of delocalization relating to earthquakes on meteorological harps.

More recent results say that the wires must be stretched in the direction perpendicular to that of approach of the disturbance not yet sensitive and that on the other hand, it would have been found that on two lines stretched perpendicular to each other there is always only one that reacts.

The remark about the wires stretched in the direction perpendicular to the direction of displacement of the disturbance is vague because the harp is not symmetrical because of the different diameter of each string; then it seems that the harp oriented in a well determined direction, that of the North of Form (if it is quite isolated in nature) must then give the most powerful effect.

This meteorological harp also expresses an effect in the process of localization. At the time of the songs it emits, there are fields of Taofel which are present. That is to say that we are faced with a phenomenon where the local is deformed but there is no substitution therefore no appearance of OF as a support. This harp is a localized form but still has an Ext.

In the case of earthquakes, we have shifts in the terrestrial globe, not measurable in position since the landmarks are on the run, but through these shifts other landmarks are formed and these are modeled on the pressure forces, them, localized and on other parameters. It turns out that the earthquake is caused by a form that cannot be located. This form happens to exist through a localized structure or something else. The localized structure may be a disappearance of rocks with pressures or something else. In the case of the meteorological harp, it is not a form which is not localizable which intervenes. She is a completely localized form that has an Ext. A fleeing form uses the local to realize itself, but as its name suggests, it is made up of fleeing pieces; these cannot be indexed by a sequence of integers. There appears a shift in the numeration. A fleeing form relocates. In the case of the weather harp, there is additionally a channel.

L. and MT Sprink immersed themselves in the work of V. Bjerknes [6] and noticed that this physicist noted before the First World War the formal equivalence between an electrodynamic field and a hydrodynamic field. V. Bjerkness used this equivalence in his calculations of "hydrodynamics" without drawing any other conclusions. However, it was only after the Second World War, and faced with the fact that the speed of the advancement of solar prominences increased during eruptions, and that this acceleration seemed to be due to a mysterious and unknown force, that we began to glimpse the extraordinary significance of this analogy. At the current stage of research, we are still at the simple observation of the existence of the hydrodynamic fields of Bjerkness. V. Bjerknes wrote [6](in volume 1, p. 25) "we must indeed regard as a secret of nature, the scope of which we are still very far from knowing, the deep analogies of the hydrodynamic field and the hydrodynamic field electricity and, likewise, with the magnetic field. There must be between the two series of phenomena a relationship little known today for a system of fluids as general (permanent hydrodynamic field) as the one we have considered, can move only in accordance with the formulas electrostatic and magnetic". Further "We will leave aside the possible significance of these analogies from the physical and philosophical points of view. We only look at objective facts which in practice have considerable significance. The equations of hydrodynamics make it possible to use the same results, the same methods and the same modes of intuitive representation in very different fields of physics". This analogy was limited to the study of solar prominences.

The Sprinks considered it reasonable to admit the existence of analogous fields also on the terrestrial globe and to seek there the cause remained mysterious of the phenomenon which will be described hereafter. It is not known whether L. Sprink tried to explain earthquakes by this analogy between fields. Nevertheless the concepts we are developing were not known to Sprink and they tried to express them in the usual language although they felt that they were facing something else...

Let's see their study on the structuring of stones. The Sprinks, during their experiments, removed fired blocks from lime kilns with a geometric spatial structuring that did not exist before firing. Naturally, their device operated near the ovens and these observations were only observed during the operation of the device.

They were able to observe two types of structuring: one in rods (generally sections in pentagon or hexagon, kind of basaltic structuring "in organs", the other in "honeycombs" (kind of structured terrain of the Tundra) The first is identical to that of band clouds, the second to that of "lacunar" clouds. The structures have been reproduced in laboratories with smoke. The aerodynamic conditions necessary and sufficient for their formation are well known.

J. Coulomb and J. Loisel have given a description of convection phenomena which make it possible to establish certain equivalences between clouds with a “lunar structure” and the structured stones of L. and MT Sprink. Let's see what J. Coulomb and J. Loisel say.

“As early as 1900, Bénard had studied experimentally, in an almost definitive way, the convective vibrations in a layer of viscous liquid, uniformly heated from above. The layer breaks up into prismatic cells of roughly uniform dimensions, in the center of which the liquid rises to descend again along the walls. Bénard gave this organization the name of “cellular vortices”. In steady state, the cells are almost regular hexagons. If the liquid is made to flow on a hot plate (terada) the cells are replaced by rollers parallel to the lines of slopes which are called “band vortices”.

“The theory of “thermoconvective” circulations in viscous liquids was initiated by Rayleigh, starting from Boussinesq's equations, and perfected among others by Jeffreys”.

Attempts to verify Rayleigh's theory have generally given fairly good results. The checks can relate to the minimum transverse dimensions of the stable cells and also to the importance of the heating necessary for start-up. In fact, for moderate heating, if the liquid's calorific viscosity and conductivity are high enough, a particle moving under the action of a difference in density would do so so slowly that it would have time to settle. temperature equilibrium with its surroundings before having traveled an appreciable path, and thus canceling out this difference in density. The particle thus does not move appreciably, and one then obtains a curious stable preventive state. In support, excessive heating would lead to the sudden replacement of cellular movement by disorganized turbulent movement, but the theory does not yet provide for this latter phenomenon. »

“Convective circulations in air are much less well known than circulations in liquids. »

The Sprinks, in addition to the structuring mentioned above, had often found in their samples taken from the ovens, stones with a radiated structuring. Contrary to what is observed on oolites with radiated structure, here the rays are not in general straight lines, but are curved parabolically and one does not find in the center of the geometric system the slightest trace of a crystal or of a fossil. This spatial structuring is due, for the Sprinks, to the existence of an auxiliary electric field, out of connection with the stone itself and to the polarization of the particles electrified by this field. This structure is reminiscent, as L. Sprink points out, of that of the debris of a racing car that fell in 1947 in Sikhote-Alinsk, in Siberia. This was also the first time that we encountered such a structure for a meteor. In the case of the “Pierres de tonnerre” of the chalk of champagne and of the oolites with radiated structure of Cettigien of the Ardèche, it seems that there is a field which structures the stone but the starting point of this field is localized by the debris of a crystal or a fossil. This fossil can be whole as is often the case in Champagne.

L. Sprink made a very interesting point about stones with a “honeycomb” structure. He had been struck by the resemblance of their appearance to that of the surface of the moon. He says: “For stones, the origin of these craters is beyond doubt: it is due to stationary vortices, generated by mass transverse vibrations”.

“It would be quite plausible to admit that the craters of the moon are not due to meteoric bombardments, because the structures of the lunar surface offer disturbing analogies, if not a complete identity with the structural shears which determine the flaking of the surfaces of our stones. It seems likely to us that the formation of sunspots with their powerful magnetic fields goes back to analogous causes, that is to say standing waves, generating more or less stable vortices of electrified matter. As for the origin of these waves (in the last two demonstrations) we have for the moment the slightest clue. Naturally L. Sprink did not know that his device was emitting eifs at the EFF level and the Taofel Field 1 I 1 1 . When such a Taofel Field is detected from the decalaire which is at the point of intersection of 2 discharges in a cross between the spark gaps (which only happened very rarely in the case of the assembly of Sprinkles since they did not know the optimal conditions for the success of the

phenomenon) privileged zones appear in the space surrounding the device, which are like weakened echoes of the decalare. They constitute a localization neighborhood<sup>8</sup>. The decalare and all of these zones behave like “a fleeing form”.<sup>9</sup>

In the case of the structured pebbles of L. and MT Sprink, there is a disturbing fact at first sight, it seems that the ores behave as if they were plastic and yet in the furnaces at the temperature of 1100 to 1200°, they are certainly not and keep their primitive forms. The same phenomenon is found in nature for oolites and modules which interpenetrate without any mechanical deformation. Here is what Mr. Cayenne, who has extensively studied the plasticity of oolites, says:

“Impression deformation has long been reported and repeatedly invoked to demonstrate the plasticity of oolites. Juxtaposed oolites penetrate more or less deeply into each other, like “impressed pebbles”. If we come to separate them, their surface is hollowed out with small cupules, giving the measure of the impression”.

“The phenomenon does not involve any difference in relative duration, because an individual who sinks into a neighboring oolite is in turn impressed by another oolite. The deformation occurs without breakage of the sheets, thus testifying to a certain plasticity of the material. In my opinion, this matter of plasticity does not necessarily evoke that of soft matter, and this is so true that we have only ever observed oolites in the process of formation on the edge of the reefs and on the shores of the Salt Lake. are soft. Furthermore, I have noted many examples of ferruginous oolites deeply set in the debris of molluscs that we do not imagine to be plastic at all” [7].

The plasticity of rocks and crystals is well known. It is well known that, without the action of a continuous and immutably directed force, any solid deforms slowly. What surprised the Sprinks in their structured stones was the speed with which these structures appeared, and the fact that the sheet structure of the limestone remains without influence on the structuring. These two structures interpenetrate without destroying each other. They could not give any explanation to this phenomenon but the observations of Mr. Cayeux confirmed the existence of analogous facts.

L.Sprink thought of hydrodynamics to explain such phenomena and he sought that it could be the nature of the wave capable of giving similar vortices in very viscous media; it is a transverse wave. he had first thought with his wife of an electromagnetic wave.

Hence if we follow his approach, the first field of Taoefel (since it is about him), behaves like an electromagnetic wave. And we fall back into the points of view of Bélizal-Chaumery of before the last war, who also thought of electromagnetic waves for the Emissions due to the Forms. This point of view was followed by J.de La Foye and others a few years ago. Can we axiomatize the existence of transverse waves which are not of known nature? what we call the eifs at the EFF level and the Taofel Fields? We cannot speak of these localized notions because we use a language and representations where we try as much as possible to escape localization. of the ovens, the Sprinks were able to discern three different structures.

The "honeycomb" structure: the imprints are generally in the planes parallel to the planes of the rock deposits and are arranged in almost parallel rows, which thus gave a very clear image of the elastic vibrations of a solid under the influence of a transverse wave. And if we express ourselves in the language of vibrations, we would have to make lines of hyperbolic currents.

The structure of stones which peel like an onion; especially in the kidneys of the limestone: what is remarkable is that whatever the origin of the kidney, we always obtain the same thickness of the peels. the starting point used by L.Sprink for the calculation of the acting wavelength. In the language of vibrations we would be dealing with elliptical current lines.

The structuring in rods, the length of which can reach several tens of centimeters. Mathematically, it should be possible to achieve this structuring for the two preceding cases, on condition that the limits of the two opposite cases of a vibrating cell are rejected ad infinitum. Obviously this is only possible in the direction parallel to that of the layers of the deposits, otherwise there are structural discontinuities and reflective surfaces. Bherknes pointed it out that way. Except the structuring in honeycombs, one can with the two others by natural way, although in a completely exceptional way. Gold,

<sup>8</sup> Location neighborhood or voiloc.

<sup>9</sup> The fleeing form is partly delocalized: we can say that its localization contains its delocalization.

with their devices, in operation, the Sprinks had them regularly; but naturally, let us remember, the correct operation of their device was only obtained after long start-up times, and when they cut off the high voltage, there was a very long recovery time after this high voltage had been established. In conclusion, one detects with the phenomenon indicated above on stones a decalaire and the C. of T. 1 I 1 1 .

Exercise : We give ourselves a dihedron with an angle of  $53^\circ$  - we will make it by 2 identical cardboard rectangles, glued by the longest side (height of this edge: 40 cm) -

A “screen” is produced with such dihedral angles of  $53^\circ$ .

They are placed on a table without a drawer P

1) Show that in a close vicinity of this form, we detect the C. of T.

$$1 \text{ I } \text{----} 1 \text{ T}$$

$$2 \text{ I } \text{---} 1 \text{ T}$$

$$3 \text{ I } \text{---} 1 \text{ T}$$

$$\text{TI} \text{ -----} 1 \sim 4$$

2) Check that if the table has drawers, in general the screen shape only emits eifs at the EFF level.

Note :

If we take a representation  $R_i$  such that we consider that the only possible eifs are those of the EFF spectrum, then we will only detect some of these eifs.of the EFF spectrum

If we take a representation  $R_2$  - which is ours - such as we have considered other possibilities then we detect C. of T..

We can then consider  $R_i$  as subtending  $R_2$  and place structures in  $R_i$  and  $R_2$  from this.

3) We place a solid or hollow ball with a diameter of 8 to 10 cm. in dihedral

Check that we obtain the C. of T..

3 I -----1 T

TI -----1 ~4

T i -----1 T

This may change depending on the location of the ball

Place several balls

Check that we can reach the C. de T.

~22 I -----1 ~22

~23 I -----1 ~23

We replace the balls with glass marbles: check that we no longer have C. de T. but only

## */ Forms and electric fields - Works of Léon and Marie-Thérèse Sprink*

In an attempt to determine the nature of these famous emissions, the Sprinks made laborious tests from the years 1951 to 1953 and they had added to their device (comprising an octagonal frame, spark gaps, stabilized high voltage, frame support), a magnetic field variable and this in 1952. The frequency of the magnetic field was not very high: two megacycles at the most. Some sort of resonance seemed to occur with certain frequencies of the magnetic field. The resonant frequencies formed a discrete 1-2-3 series... They concluded that their device was both an amplifier and an acoustic resonator. Here we have analogies with usual devices; this is also what is found when using a fairly cylindrical tree trunk of radius  $r$ ; one can find a propagation of the eifs which resembles a kind of rectilinear optics, with however different laws (propagation between the circle of radius  $r$  and the coplanar and concentric circle of radius  $2r$ ) [1].

Naturally this analogy was reinforced by remarks made by L. Sprink, such as the following: acoustic resonators (a Helmholtz sphere or the pots of Romanesque churches) only respond to the vibrations of the notes for which they have been tuned, while a electromagnetic resonator only responds a little better to the frequency which is its own.

But L. Sprink says "our device is not an autonomous transmitter, but a resonator whose exciter is elsewhere. He also makes a distinction according to whether he used the low frequencies of the magnetic field (up to 25,000 cycles/s) where he says that then it is the acoustic resonance whereas between the 2 we would have a mixture of 2 types of resonances. Above 100,000 cycles/s, he noticed that he had waves of a hydrodynamic nature.

Let's not forget, L. Sprink saw the world only in its localized presentation despite that "his approach was to assemble whereas the usual scientific approach is to divide" Einstein had told him during a visit that L. Sprink returned to him before Einstein's departure from Germany.

But the Sprinks had clearly realized, despite the fact that they were thinking of resonances, that the effects, in particular, in vertical furnaces could not be attributed to electrostatic fields because an electrostatic field due to a partially localized charge could not have a range equal to that which they had observed on rows of ovens separated by several tens of meters and this, without the effect being weakened. Because we know that the electrostatic field decreases as the square of the distance. In addition, the effects on the aligned ovens were not, over time, felt in order of distance from the source but the first oven got carried away then the third, the fourth, then the second etc... and this reoccurred in this order after shutting down the device and turning the high voltage back on. Thus, thanks to the high frequencies of the magnetic field, they had the assurance of a new phenomenon, the effects of which appeared as waves of a hydrodynamic nature. They measured the thickness of the "peels" of the structured stones in the case of elliptical currents and this gave them a wavelength (if they assumed they were dealing with "mass" waves) of about 7 mm .

The "meteorological harp", too, can be considered from the point of view of L. Sprink as a resonator whose frequency is audible. The measured wavelength still justifies the name "wave form" given to these emissions, as had been supposed by Chaumery, Belizal and others. It must be admitted that the temptation is great to confuse them with waves. But if we consider that the universe has in it a delocalized existence, we notice that certain notions of the delocalized resemble notions of the localized world.

Let's take this opportunity to say a few more words about ancient harps. They have been little reported by the musicians. A book by Georges Kastner [2] deals in part with the following subjects:

- The harp of Aeolus
- Origin of music
- Origin of the myth of the Harmony of the Spheres
- Sound phenomena, examples taken from the Bible, from Greco-Roman antiquity
- Travel stories
- Echoes
- Harmonies of caves, rocks, waterfalls
- Vegetable harmonies.

We cannot cover all these topics here. Some, like many echoes, are explained in physics by the reflection of sound on walls, but others, like the music of the spheres, are much more difficult to study because they are heard by a few people at certain times; it can also be heard during doublings. Samuel Franeric<sup>1</sup> had such an experience. L. Sprink seems to have heard this music one night near his camera. Naturally, it does not appear that it was the wind that blew on the spark gaps to produce these sounds, the device being enclosed. We will nevertheless, here, look at these Aeolus harps and so-called meteorological harps.

<sup>1</sup> Researcher from the ARK'ALL group

The origin of the Aeolus harp is not known. "...Legends and even true stories, says Kastner, reveal the existence of natural Aeolus harps, produced by the rustling of foliage, by the friction of reeds and tall grass waving in the breeze. .". Nature was able to inspire researchers, who used the wind to excite the strings of instruments they made.

Kastner has a slight tendency to reject any attempt at a non-rational approach - which makes him very attached to instruments that work with the wind -.

The Jesuit Father Kircher and shortly before him Jean-Baptiste Porta (Neapolitan born around 1540 approximately) studied treatises by researchers who preceded them on Aeolian harps and trumpets and sound pipes. Similarly, Father Bartoli, also a Jesuit, after Kircher and Porta, studied all these works; an English physicist also, William Jones and later Matthew Young (from Dublin) mathematician treated the harp of Aeolus scientifically. It is obvious that this list is not exhaustive; for more precise details it is good to relate to the work of Kichner and certainly that anonymous researchers also obtained results; often on the death of the researcher, the writings and apparatus are put back in attics and after several moves end up in the fire or in the trash and we have even seen in some cases that the families, upon the death of the brilliant discoverer, hurry to destroy everything because of fear of witchcraft which could have interfered in these works. Under the pretext of prudence and prudery, it is an attitude of profound stupidity.

We have already seen that L. Sprink had knowledge, perhaps through the work of Kastner, of a meteorological harp, that of Ventan, provost of Burkly near Basel.

The meteorological name was given by Father Gattoni who had made a gigantic harp (he called it: meteorological harmonica).

Ventan's was made of 15 metal ropes and guts, attached to the top of a high tower about 85 meters and 150 paces from his house to which he fixed the ropes so as to form an inclined plane. The instrument first gave results of a pleasant harmony, but soon the agreement was broken by the atmospheric influences and it is then that the inventor of this instrument imagined to make an instrument of meteorological observation thanks to the intonations of the strings resulting from the various states of the atmosphere.

Let us see the remarks of Canon Gattoni:

- 1) It does not matter whether the metal wires are insulated.
- 2) You don't hear the sound quivering when the wind blows violently and shakes the wires, but only when the air is relatively calm.
- 3) No sound is obtained when the wires are less than 10 m long, annealed wires are more favourable.
- 4) The wires produce this same quivering, but less sonorous, when they are stretched with glass supports; it is still less noticeable when they are stretched with silk cords.  
They are electrified at the approach of storm clouds, like any insulated metal. However, these sounds cannot be attributed to electricity, as some have wanted to maintain without any foundation, adds the canon (it is a question here of static electricity). Nevertheless adds Bellani (in a footnote reported by Kastner) if it is about dynamic electricity, one can obtain sounds but let us notice in this case there was no dynamic electricity.
- 5) The variation in the state of the atmosphere for Gattoni is the cause of the effects produced by the harmony of the threads: for if the sky is serene or rainy for a long time, no quivering is observed in the threads.
- 6) It is proven that sounds are not produced by accidental causes, such as the impact of birds, insects...
- 7) It is also proven that changes in temperature only affect metal wires by successive expansions or contractions, producing quivers which depend on the relaxation or stretching of the wire.

In summary, it emerges from these remarks of Canon Gattoni, that the meteorological harp is not excited only by the wind as the aeolian harp must be, although certain aeolian harps certainly have characteristics of the meteorological harps, but that the changes of time that must occur are signaled by this instrument. It therefore seems that a change of weather is necessary and that the phenomenon which interests us occurs before the change of weather. It is, for the observer attached to the harp, a forerunner.

It appears from the high-field eifs of Taofel. We are going to find ourselves with a partially delocalized process which is localized. Note that these meteorological harps have an ext (a harp usually does not; moreover, a harp does not emit Taofel fields except for certain very specific compositions). Could a variation in atmospheric pressure initiate the phenomenon of the singing of the strings? It is not impossible. But it is interesting to think back to the noises reminiscent of those of jets of pressurized steam which were heard near the Keely bottles [3] (the noises are different in sound from the weather harps but can be related to them by the relocation phenomenon). If we consider the occultist point of view, we can relate these phenomena to the "ether of sounds". This ether is in reality the Aether of which L. Boutard speaks [4]. The alchemists also speak of "the ether of heat"; they distinguish several "ethers" [5]. This corresponds to their unexpressed sensations, and very vague for most of them (vague in the sense that the concept of ether for them was isolated, not attached to a field of consistency).

The aether can contain the small snakes of which L. Boutard speaks but also more elaborate notions. The little snakes are only the result of a projection of a fundamental structure as for the usual field of coherence, the atoms, and fundamental particles are the result of a search for the materials of assemblies of the

matter. The sounds that came out of the bottles associated with Keely's engine, such as those of the meteorological harps, David's Harp, are on the same level as the production of glycerine, colors, peptides etc. which come out of the generator in the form of Boutard's rhombe. It is the same, moreover, with the music of the spheres, which is a localization. At times, which L. Sprink could not control and very rarely, at night, his camera played the role of L. Boutard's rhombus [4]. The music of the spheres can also be heard during a doubling; it is the one that doubles which is the equivalent of the device with a rhombus; it is the state obtained by duplication which gives this possibility but certain individuals can hear it while looking at the starry sky, on a summer evening, in an atmosphere of solitude <sup>2</sup> [3].

<sup>2</sup> S. Franeric actually heard the music of the spheres under such conditions.

“Error does not become truth  
because it spreads and multiplies.  
Truth does not become error  
because no one sees it. »

■ Gandhi

Gandhi (Mohandas Karamchand, known as the Mahatma, that is to say the great soul) (1867-1948), ascetic and patriot of India.

He studied law in Great Britain and then settled in South Africa in 1893. He endeavored to improve the lot of his co-religionists who worked in this region. In 1914 he returned to India and agreed to support the policy of the Anglo-Americans in order to obtain the independence of his country. Britain not having kept its promise, he preached and applied the principle of non-resistance, of non-participation in all violence, and also of non-participation in the coercion of the courts, taxes, military service of the British administration.

Imprisoned on several occasions, he practiced a hunger strike and thus obtained concessions from the English and also from his compatriots (appeasement of the uprising of 1921); he was devoting himself, by a seventeenth fast, to the fight against the civil war between Hindus and Muslims, which was tearing apart India which had become independent, when he was assassinated in Delhi on January 30, 1948. He wrote an autobiography: “History of my experiences with the truth” (1925).

devices intended to  
improve certain chemical,  
thermal, metallurgical reactions  
and whose goal is  
an energy saving... and  
financial in the future world.

## 1) Introduction

We present in this report the validity of physical observations and industrial results covering a period of nearly 130 years. All of this work relating to changes in the state of matter began with analyzes and scientific remarks made around 1850 and published in various reports by the Academy of Sciences. Practical applications on various industries were carried out in France from 1920 to 1955 on an experimental basis. Currently, a resumption and continuation of previous developments are considerably strengthened thanks to the technological fallout from the measurement of certain physical fields in space following NASA experiments and astrophysical information collected by Soviet satellites.

Moreover, newly experimented effects at the level of emissions, absorption, adsorption, resonances due to forms oriented in space, now make it possible to clarify certain variables or phenomena considered as difficult to reproduce for lack of being able to control the parameters, even by measurements, of classical fine physics.

## 2) Part 1: Principles of Sprink-Ravatin devices made experimentally in operational models and practical advantages.

a) Summary of patent n° 1,005,532 issued on December 26, 1951 to Mr. Léon Sprink and Mrs. MT Roussel.

"...improvements in some remarkable chemical reactions such as combustion reaction, reduction, hydrogenation, etc. by the use of metal spikes mounted on an insulating support in the form of a frame and connected to the two poles of a high voltage direct current generator..."

Experience proves that such a device put into operation near autoclaves, cement and ore kilns allows reductions in operating time from 24 hours to just 3 hours with a calorie saving of 50% maximum.

b) Summary of patent no. 966,735 issued on April 8, 1950 to Mr. Léon Sprink and Mrs. MT Roussel.

"... Finding that a large number of changes in the states of matter or reactions depend, in addition to the classic factors of temperature, pressure, etc., on electrical or magnetic phenomena produced nearby from a certain degree of activation of effluvium of crossed electrons and placed according to a determined orientation. ...» The experiment shows that for reactions such as the clinkering of cements, the decarbonation of lime, the saponifications, the reduction of ores, and during the use of the device near the products to be transformed, there is always a gain in operating time and fuel used.

c) Patent application no. 78-21083 of July 13, 1978 by Mr. Jacques Ravatin, Doctor of Science, ESCIL Engineer.

Summary: The subject of the invention is an apparatus making it possible to amplify, according to a principle known as "Localization", the effects due to simple geometric shapes by associating them with a device generating electric, magnetic and electromagnetic fields, as well as to a closed polygonal frame with the character of right and left Moebius strips. Are associated with the volume generated by the devices of natural or artificial minerals such as:

- Pyrargyrite or Argyrhyrosis
- Proustite or Red Silver
- Obsidian or volcanic vitreous paste with low water content
- Carborandum or Silicon Carbide: C Si

whose amplifying power on the effects obtained has been observed, as well as conferring a so-called "fractal" character (well known in mathematics) to the parameters of the close physical fields.

The practical interest of the variation in the value of close physical fields is directly linked to changes in the state of matter with a considerable acceleration of the chemical and thermal reactions sought for obtaining conventional industrial products or new steel products with a reduction of the energy potential usually required by at least 30%.

The additional advantage of J. Ravatin's device is positively materialized by the instantaneous obtaining of the desired phenomenon(s), whereas with L. Sprink's device the start-up time could sometimes take a few days to several weeks.

## 3) Part II Different Types of Observations and Experiences That Lead Patent Applicants

L. and MT Sprink have made experimental devices capable of saving time, fuels and obtaining better or new manufactured products.

## a) General remark

The observation of certain natural phenomena in physics, chemistry, biology, sometimes allows, by applying a practical analogy, to realize in small what nature does in large or at least to draw a conclusion which will help man in art., industry or science. Thus the knowledge of interstellar radiation in vacuum allowed the realization of radio lamps, the understanding of radioactivity radiation led to the realization of "nuclear" and the sending of electric current in the ground allowed the Schlumberger brothers to build an empire based on the search for oil since 1912.

## b) How L. Sprink was brought to be interested in the problems of the Forms, their action and the fields of force compared to bacterial or chemical reactions at various temperatures.

Léon Sprink comes from an old Blelo-Russian Baltic family allied to the Tolstoi. Very early on he showed qualities of observation, analysis and realization whose originality challenged him to pragmatism. For example: in his 15th year his father took him to visit a brewery in his native country where it was difficult to obtain, by the processes then known, a beer of poor quality which gave a lot of tablature to professional brewers.

Barely returned from this visit, the young L. Sprink imagined a model of tanks whose alloy and especially the forms allowed the accelerated fermentation of the hops, giving a beer of much better quality and more quickly than by the usual artifacts.

In view of the intelligently executed realization of this model and in view of the positive results obtained, his family directed him to the Polytechnic Institute of Saint Petersburg from which he graduated before the First World War.

Around 1913 L. Sprink had the chance to observe an unusual phenomenon of the solar corona during an eclipse. The emissions he observed gave the image of a cross of Saint Andrew outside the halo, which is an extremely rare phenomenon and moreover unexplained at this time.

The main work of observations and attempts to correlate phenomena related to solar plasma, and the aurora borealis were made by Gassendi in 1621. Have done work on the subject in order to "understand" the interlinking of phenomena, Cassini 1686, Halley 1716, De Mairan 1726, Arago 1855, Angot in 1897 etc... a special place goes to Auguste Bravais, author of the theory of networks applied to the intimate structure of crystals who established correlations between these structures by comparing phenomena relating to crystals. halos, parhelia, aphelia and unusual diffractions observable in the Earth's atmosphere.

This French physicist, member of the Academy of Sciences in 1854 tried to connect the close and distant observable effects by similarities such as Sprink will use some later.

It should be specified here that from Gassendi until 1937, the total time of the multiple observations of the solar corona during the eclipses did not exceed a few hours due to the very short time of the possibility of observation of the total eclipse [6 ],

L. Sprink therefore had not only the possibility of making an exceptional observation but above all the intuition of bringing closer to the vision of these plasma effluvia, the then brand new notions of electricity and propagation of electromagnetic waves (developed by Ruumkorff and Hertz) d a possibility of acting on the level of the ground on the phenomena of combustion and heat by combining especially thermal reactions of the currents of static electricity emitted by a stabilized generator.

At that time, fertile in multiple and primordial discoveries, it turned out that many intuitions could be crowned with success at the level of technological reality, while mathematical theory could only account for the reality of phenomena for a few years. later. This was the case for Sprink's devices in its first trials.

The events of the First World War as well as those of the Russian Revolution earned L. Sprink imprisonment in the Saint Peter and Paul Fortress. He came out ALIVE, but remained physically very ill.

He emigrated to France where he married Marie Thérèse Roussel, granddaughter of a famous French geologist.

The couple then worked together on all the theoretical and practical achievements aimed at obtaining new chemical reactions at high temperature, products with new structures, by synthesizing the effects of electric fields supposed to exist in the upper atmosphere with thermal gradients. more or less high obtained by various combustions.

During this period, the Sprinks were in frequent contact with Maurice and Louis de Broglie, the Cottons, the Curies, who understood Sprink's work as the dawning era of all new chemistry, all new physics and the opening towards a fruitful understanding of the true field relationships existing in the solar system.

The Sprinks went to Germany in 1930 and met Einstein at length to explain their work to him.

The conclusion of the latter can be summed up in this sentence: "I try, says Einstein, to analyze the universe and you, you recreate it before our eyes".

## c) Sprink's fundamental experiments and first observations of facts not yet observed by the predecessors: Coulomb, Faraday, Gauss, Whimshurt...

We have seen above how Sprink, based on his observation of a space phenomenon, had connected the new possibilities of carrying out chemical and thermal reactions by associating a stabilized high electrical voltage which at the time could be supposed to have had this voltage. exist in interstellar spaces and especially around the sun. It should be noted that the concept of solar electro-jet came only after the discovery of thermo-nuclear reactions and the measurements carried out by rockets and satellites.

L. Sprink therefore carried out a first rudimentary assembly consisting of a very dry circular wooden frame through which were fixed in a cross of Saint Andrew along the diagonals, metallic conductive electrodes themselves connected to a stabilized high voltage generator .

When setting up the assembly on an insulating support, a first remark was made by Sprink: the electric discharge from the electrodes, instead of passing along the shortest path, the case of a classic arc, was heading towards the opposite electrode. Which means that the electrical discharges crossed in the axial extension of the 4 electrodes, also forming a cross of Saint Andrew. At the point of intersection of two effluvia then a new fact, not observed until then, occurred and which the known formulas or laws of electrostatics do not account for. Only the so-called "power of the spikes" effect on a flame is known.

We insert here a remark made by Buffon and recorded by him in a little-known text that Mr. Cotton, the physicist who invented the famous balance, had shown to Sprink: "In the 18th century the aurora borealis were frequent in France. The dates of aurora sightings according to Buffon corresponded to frequent fires ravaging entire villages in northern France and Europe; the constructions were made of wood (the wood in the constructions being of more consequent use than now). Buffon, an observer of all natural phenomena, establishes a relationship between the two associated and simultaneous facts as well as the performance of blast furnaces with fires and the aurora borealis".

L. Sprink made a similar observation in 1938 during the aurora of January 15 visible in France accompanied by the destruction of boilers and chimneys.

The Sprinks experimentally carried out a certain number of chemical and thermal reactions in closed environments: autoclaves, furnaces, coke ovens, etc. by operating their device in a cross pattern nearby, noting very regularly and punctually the actual calories used in the classic reaction and the times spent to obtain industrially manufactured products according to the demand of the national and international markets in order to be able to compare their own production times and the real savings made in normally used fuel.

The first results were promising enough to be addressed to the industries concerned. We will briefly review a few of them.

d) Origin of industrialization and improvements of Sprink's device from 1923 to 1950

i) Fundamental discovery of the autocorrelation of irregularities in the yield of a soap factory with respect to the activity cycle of the solar plasma and the cycle of the earth's electric field.

In 1923 Sprink, in Strasbourg, owned a process for manufacturing soaps with high detergent power that a stearin factory had adopted. According to the boss of the factory himself born in this industry, it was known that the manufacturing "recipes" only "lasted" for a certain time with irregularities in performance and that then something else had to be found...

L. Sprink and his wife then carried out studies in autoclaves in which, with regard to production statistics, various cyclic laws could be established by a rapid harmonic analysis of the progress curves of reactions in autoclaves with regard to various daily, night and seasonal parameters. (equinoxes and solstices), annual, decennial etc., linked on the one hand to the positions of the moon and the sun and on the other hand to the terrestrial vertical electrical gradient. A correlation could be established between the chemical thermal reactions in a vacuum with the aqueous and terrestrial tides as well as with an aerial "electric tide" (terrestrial electric vertical gradient) and the terrestrial horizontal electrotelluric activity which we currently know (since 1952) correlation formulas with terrestrial magnetism. It should be noted in parenthesis that the worldwide industrial developments of applied geophysics for the discovery of hydrocarbons have only been possible through the detailed analysis of several million measurement points of these various parameters, the effects of which we began in 1980 to master. laws.

Commissioning of the first device

The conclusions of the Sprinks were that to reduce the manufacturing from 11 p.m. to 3 a.m. (!) it was necessary to subtract the autoclaves and their reactions to the action of the aforementioned fields. A device for "grounding" the press frames was carried out which had the effect that in 1936 the factory was operating at 150% efficiency compared to 1932 taking into account the working hours reduced to 40 hours instead of 48 hours and without changing the "recipes".

However, although the application of the new process preserved the plant from the most troublesome fluctuations in its production, there were still peaks in the qualities and yields above the critical threshold.

ii) Continuation of the industrial work of the Sprinks at their laboratory in Meaux (Seine et Marne) 1938-1940 and at the Cimenterie de Port de France from 1943 to 1944 with the aim of obtaining massive fuel savings.

Around the 1930s, Mrs. Sprink was also studying the problem of the formation of cements at low temperature and had arrived at a very beautiful manufacturing process using the horizontal Mecker furnace. However, as in stearinage, the results and the yields presented variations linked to another unknown factor not linked to the terrestrial electric fields nor to the lunar and solar tides as regards the Newtonian action.

However, based on certain observations of the solar corona on the one hand and the appearance of the spots on the other hand, by correlating the anarchic deviations from the variations in the quality of the cements, it was established that the deviations were directly linked to the electromagnetic activity of the corona (currently called F electro-jet) and to a terrestrial consequence translated into our upper atmosphere around 100 km altitude which are the aurora borealis. In brief the law of interdependence of the phenomena of coronal radiation in relation to the two passages of the sun on the lunar nodes on the one hand and on the other hand the consultation of the variations in quality of the cements of Port de France (Isère) recorded over forty years of daily analyzes allowed cross-checking.

It appeared that the tensile strength of cements analyzed from 1898 to 1939 followed the cycle known by astronomers of 18 years 11 days under the name of Sarros. This cycle corresponds to 223 lunations or 19 times the interval of 346.6 days separating two passages of the sun through the lunar node.

It turns out that the periodicity of oceanic transgressions also partly follows the same law. As above, there appeared a correlation between these various phenomena and the physico-chemical balances of the reactions analyzed. It was then that the Sprinks used their second device consisting of 4 cross-shaped aerial electrodes placed on a circle and powered by a stabilized DC high voltage source. This device was the subject of the patents mentioned at the beginning of our report, Chapter 1,1,2.

The coupling of the two devices was tried with profit at the glass works of Mers les Bains in 1949 where significant rises in temperature were observed for a reduction in the tonnage in combustion of pulverulent coal and fuel oil. Tests were also carried out in Brazil in 1951 in a lime potash plant. But the results remained inconsistent because the situation is complicated by the fact that the solar periods do not have a rigorously fixed duration and can present random periods of encounter with the moon according to variations ranging from 9 to 15 years.

- e) Attempt to develop a theory in the face of the complexity of the phenomena to fully control the chemical and thermal results, work from 1951 to 1955.

In view of the achievements already obtained on the lime kilns and in the manufacture of cement, the important economic element was reflected in a gain in fuel (coming from the same coal mine) which could reach a rate of 50% without clinker. However, this economy did not follow a known law, which is acceptable considering the complex remote phenomena on which depend the thermal reactions in chemistry of high temperatures, the states of matter.

In short, the Sprinks carried out a series of tests which led to the following conclusions: at low frequencies of the magnetic field:

- 1) up to about 25,000 c/s the acceleration effects are related to electromagnetic resonance; at higher frequencies (from 100,000 c/s), an acoustic resonance is established.
- 2) the Sprink device is not a self-contained transmitter, but a local amplifying resonator whose excitation lies elsewhere.

- 1) At low frequency it is an electromagnetic resonator also thwarted by terrestrial radio emissions

- 2) For high frequencies, the effective waves are of a mass nature with a hydrodynamic character. After the tests on rows of vertical cement kilns, the only hypothesis of the effects observed simply due to electrostatic fields was insufficient, a spatially localized electric charge not being able to have an action over several tens of meters without any weakening, the electrostatic field decreasing with the square of the distance. So there was something else, because the device in its applications *was only effective oriented perpendicular to the earth's magnetic field*.

There remained a fundamental point to be elucidated: what was *the primary radiation source*? the device being a "relay-resonator-amplifier".

During the tests on rows of lime kilns, another curious fact experimentally shows that the rise in temperature, the intense drafts and the unusual thermal reactions first appear at well-determined distances from the device arranged in zones. circular analogous to the known images of the rings of satum with similarities of gaps reminiscent of the asteroid belts around the sun.

A phenomenology causing such effects was unknown until now and the Sprinks seem to be the first to have observed all these facts, to have analyzed them with the means at their disposal and above all to *make immediate industrial use of them*.

For the nature of this radiation, the Sprinks were reduced to hypotheses approaching the theses of Louis de Broglie on wave mechanics, in particular in the two different states: the vectorial and the pseudo-scalar as valid for "mesons" or heavy electrons as for the "photons". According to Maurice de Broglie, with whom the Sprinks were linked, interactions between particles via pseudo-scalar photons would be spin interactions.

It would therefore seem that the extreme ease of establishing homopolar links in the presence of our device in operation confirms this hypothesis.

In the conclusions and the mathematical developments carried out by Sprink it emerged according to him that the terrestrial electric and magnetic fields, as well as their derivatives and known slow variations, were subjected to other rapid variations at very high frequency.

Sprink admitted that the rhythm of the discharges of the device was regulated by the magnetic field which is perpendicular to them, that is to say the earth's field whose various rhythms are those of the phenomena emanating from the solar plasma.

Sprink considered that the field of his oriented device could be described as a variable magnetic field at very high frequency, without distorting reality, especially since the intensity of the currents used remains very low.

Sprink considered to be in the field of *mass resonances* which caused this radiation to be confused with simply acoustic waves, whereas at very high frequencies it is plasma vibrations which appear.

Moreover, in relation to the effective frequencies for the desired purpose, Sprink has made *standing waves visible* by extending the electrodes with strands of red copper wire welded to the ends. On these little strands

luminous points appear located at the nodes of the waves and correspond to the two absorption lines of the spectrum of rotation of oxygen of 2.5 mm and 5 mm. This gas could be the resonator par excellence of the primitive radiation. There is an analogy at the level of the solar prominences with the strands of thin wires and their luminous phenomena; in effect, *local reinforcements* of the brilliance appear on the photos of the paths that the expelled plasma travels in the direction of the crown according to the laws of hydrodynamics.

In the hypothesis of a *mechanism of the propagation of the mass field* Sprink excludes the propagation by electromagnetic waves because of the presence of standing waves, visible on the photos of the strands of wire mentioned above since the standing waves do not radiate. It also excludes material vibrations because the transverse waves physically observed near the devices do not propagate in a gaseous medium. However, the radiation is linked to very significant ponderable effects, probably amplified by *quantum resonance* in the reacting materials. Sprink believed to be in the presence of an energy flow & *quantized impulse*. This way of seeing is in agreement with the development given by Einstein for the global weight-motive force.

In the analysis of the phenomena present there still remains that of the formation of a swirling magnetic field which can only be treated by the methods of wave physics. Sprink believed that this field could be described as a spinal field which could only be propagated by pseudo-scalar photons <sup>3</sup> following Louis de Broglie's theory of wave mechanics.

f) Stopping of theoretical and practical work of Sprink and difficulties encountered with employees.

As can be glimpsed in the summary of the Sprinks' scientific and industrial adventure, the unusual, the complex, the permanent contact with unknown variables were the daily companions of the Sprinks.

From what we can know of their relations with the great international names in science, they have always been excellent, whether Maurice de Broglie, the Curies, the Cottons, Einstein or other contemporaries. who, while having admiration for the work of Sprink, were themselves too absorbed to devote themselves to a common collaboration.

In their contacts with factory bosses, the latter not being at the head of a study or research company, very often these heads of industry saw themselves obliged to consider only the economic aspect of things and asked engineers or technicians in their company to make their willingness to collaborate available to inventors.

At this level, the Sprinks have not always met with the understanding necessary to be perfectly followed. It should also be considered that their working hypotheses, especially before 1945 (Hiroshima), could seem incomprehensible to classically trained engineers working in the factories of that time. On the other hand, with regard to the foremen and the workers, very often enthusiasm reigned in the face of the results obtained.

After the death of Marie Thérèse Sprink in 1951, Léon Sprink devoted himself more to theoretical laboratory tests and to writings intended to leave a satisfactory concretization of the ten industrial patents taken out between 1930 and 1954. The various industrial practical works of Sprink ended in 1965 for various reasons: the factories had disappeared, changed manufacture or had been reabsorbed by groups having opted for a policy or a range of different products. Moreover, Sprink had always been a relatively independent researcher and financed all his research and experiments himself in his laboratory in Seine et Marne, in Meaux, over the last years of his life.

L. Sprink built gravimeters derived from those of Jacobovitch for the study of the horizontal component of the terrestrial "g". Sprink perfected the apparatus by installing an optical effect multiplier and adding a photographic recording. For his studies, a collaboration was made with Mr and Mrs Labrouste of the Institute of Physics of the Globe and members of the International Gravimetric Bureau. The harmonic analysis revealed outside the periods like the luni-solar tides other periods and variations of horizontal "g" during the operation of the cross device.

In 1967 Sprink passed away as the last descendant of an old Baltic family of Protestant origin. His origin earned him a burial in the Cemetery of Sainte Geneviève des Bois, although he is not buried in the part reserved for the Orthodox.

#### 4) Part III

a) Continuation of the work of Sprink - New developments.

After his death, a succession of training not being assured, the work of the Sprinks would have disappeared if a few particularly well-informed people had not put on the trail of these discoveries, the future of which could be considerable, a chemical engineer, doctor of physics -mathematics which took up the known theoretical part of Sprink's devices and continued it by completing it masterfully with the contribution of new discoveries, in particular on the

<sup>3</sup> The pseudo-scalar photon hypothesis in the case of the work of L. and MT Sprink had been put forward by Maurice de Broglie.

notions of emissions and absorption due to oriented forms as well as by the notions of "Location", "Global", "Offset", "Cumular" [6].

This is Jacques Ravatin, experienced experimenter and theoretician who took over Sprink's experiments and had Professor Mesnard of the University of Lyon, director of the electronics laboratory of this University, note the amplifying power of the effects obtained in this way. than the Fractal character of these effects, of which Jean Perrin has also developed the physical consequences on the parameters of the physical fields linked to certain states of matter at the corpuscular level.

*The practical application directly usable in industry* with some of the enormous consequences that it represents is summarily exposed in the patent application of July 13, 1978 under the n°78 - 21083 deposited at the office Casalonga, 8 avenue Percier, 75008 Paris in the name of Mr. Jacques Ravatin.

b) Descriptive summary and experimental principles of the invention of Mr Jacques Ravatin.

We know from experience that certain simple geometric shapes with a minimum of symmetry manufactured in very varied materials are, when they have appropriate proportions and a certain orientation in space, the seat of effects in their close environment which, not to be explained clearly, are ascertainable:

- either on living organisms or organically dead cells.
- or on metals on which a molecular rearrangement seems to occur.

The first observers used to describe the phenomena an ill-adapted expression: "waves of form". It is more correct to say that it is more of a resonator absorbing or capturing locally a more fundamental notion than the energy emitting measurable effects following a certain orientation. But that's not it yet.

These industrially exploitable effects or more exactly become so thanks to the amplifying apparatus of Mr. Ravatin which considerably amplifies the phenomena according to a principle known as "localization" in which geometric shapes presenting a minimum of symmetry are associated with devices producing a field electricity, a magnetic or electromagnetic field modulated or not.

The various parameters allowing the amplification of the phenomena expected for industrial exploitation have been developed to the maximum. The start-up of the device to obtain the desired effects requires a time of about one hour for a noted action zone of about thirty meters.

The generator producing the electric potential must deliver a current of approximately 500 microamperes. It is gradually increased in voltage starting from zero to reach at least 124 kV.

c) Effects noted on Mr. Ravatin's operational model.

1 Action on the local terrestrial magnetic declination of approximately 6° towards the west after half an hour of operation with variations of effects according to the orientation of the frame.

2 Local action on gravitation at 100 kV of potential it is found that the local gravitational field goes to 0.9 times its value at the measurement point close to the device taking into account the drift corrections of the gravimeters and the luni-solar variation tides.

3 Local action on the refractive index of the air which increases all the more as the positive potential applied to the serum electrodes is higher.

4 Observation that in combustion reactions usually producing clinker, there is no formation of clinker during the operating time of the device and even 4 days after the voltage cut at the electrodes.

5 Decrease in the amount of fuel needed in conventional combustion reactions to achieve the same result. Saving 30% of coal is possible with a high voltage of 100 kV - 100 microamperes.

In the case of an internal combustion engine using gasoline, there is a reduction of up to 50% in fuel consumption for identical performance. However, the engine is stationary and not mounted on a vehicle taking changes of direction in space.

6 Increase from 1 to 2.3 of the solubility coefficient of a salt in water.

7 Increase in plant growth rate and size by a factor of 2 to 10.

8 Possibility of obtaining catalysis without catalyst.

d) Jacques Ravatin's device with regard to biology.

This statement has been deliberately restricted from certain possible developments *applicable to the industry*. We have discarded the important observations made at the biological level and on human behavior from the point of view of fatigue and which have been noted by entire teams of workers.

Compared to the experimental model having felt in the first tests, the elaboration of the next prototype - object of the 1978 patent application made by J. Ravatin - is based on the data of his doctoral thesis in sciences presented in 1965 on the so-called "non-Cartesian" systems under the authority of Professor Mesnard.

e) Verification of the validity of the results obtained by Mr. Ravatin.

Professor Mesnard, director of the electronics laboratory at the University of Lyon, supervised the experiments resulting from the theories of these non-Cartesian systems and monitored the experiments carried out.

It should be noted in particular that this new experimental physics theoretically and practically reveals a notion to ponder: the usual physical measurements, however fine they may be, only indirectly account for certain observable facts and in a fragmentary way.

The approach to the phenomena observed and highlighted under the supervision of Professor Mesnard by J. Ravatin involves the notion of "Fractant".

It appears that taking into account the foregoing, the findings and all the facts proposed for our analysis by the developments put forward and obtained before Professor Mesnard by J. Ravatin cannot be analyzed solely from conventional measurement methods. accounting if we can say that for the "spillover" of integrated facts; from the origin of our galactic system.

f) New ways, appropriate semantics

Understanding and mastering the desired effects requires a terminological redefinition developed by J. Ravatin in which the expressions "Global, Local, Cumular, Shifted, Cumulo-Shifted and the concept of Fractant" appear.

The aim pursued in the construction of the future prototype is to demonstrate by amplifying them the "bursting" effects of the classical space-time structure. The practical results will have industrial consequences on the level of chemistry and metallurgy - to quote only these two industries - comparable to those of the spin-offs of the conquest of space with an initially more immediate ease and a saving of obvious energy. The progress made compared to the work of Sprink from 1925 to 1965 was possible thanks to the integration of notions unknown at that time both in relation to a better knowledge of extraterrestrial space and to the improvements made by J. Ravatin .

g) Let's envision the future of a post-industrial society

We can foresee that following this work developed over decades, we find ourselves at the dawn of an era in which the conceptions mentioned above will take on more and more importance, if only in due to the global energy situation. From Léon Sprink's little sun to Jacques Ravatin's fractants don't we find ourselves faced with a reconstruction of a universe as Einstein expressed it to the Sprinks... but could we add the industrial universe of the world of tomorrow in the face of planetary responsibilities never before encountered. [4] and [5].

Let us point out the stability of the phenomena obtained by J. Ravatin and their reproducibility.

There are also thresholds which are given by the voltage, the dimensions of the device, the forms involved. If the conditions imposed are neglected for reasons of economy, it is not possible to obtain certain effects. [7], The capabilities of the Sprink device can be considerably improved by adding forms suitably chosen and arranged around the device; we thus obtain the Avaecum discovered by J. Ravatin and the fields Z and ZD discovered by J. Ravatin and AM Branca.

## *I. Introduction*

The chapter does not include an exercise. On the other hand, the examples given will make it possible to grasp the concepts. It should be read carefully. We are gradually entering into the new form of thought which makes it possible to set up a model: the Coherence Field Theory.

## *II. Structure transportation:*

Let us consider a form F, for example a living being; we talk about his condition.

Thus F -Y-ûlê—> state of F sets up what is called the path when one wants to pass from F to state (F). This creates a path.

Let's consider a shape G on which we will apply this path. We will thus obtain state(G).

Let G state G

Through the track, a “structure transport” is thus obtained. We can enrich a domain by bringing to it a concept that a priori did not exist in this domain.

We saw in the course of the <sup>st</sup> level that certain states are characterized from words written, for example, in square Hebrew. This corresponds to states that are no longer representable in today's thought, but square Hebrew has kept the information that allows us to go back to the state.

Among the states, some will relate to an impossibility for the human being to approach a domain; it can be that the result of a lack of knowledge, of wisdom of the one who works, or then the index that the mode of thought adopted is not adequate or that certain concepts are not accessible to human thought. This last remark disappears if one has faith in the human being and especially the thought, since nothing exists apart from it.

## *III. COHERENCE - THE FIELDS OF COHERENCE THE LOCAL, THE GLOBAL, THE IDATHEME*

Necessity is a concept often used in the everyday world. It intervenes in this course as an effect of a tension between concepts, situations.

As we will see later, we will only very rarely give definitions. These freeze a thought. They excel in rational thought which is static thought: which means that this thought evolves over time but is not expressed in the moment, that is to say that a definition does not have currency in the thought that we have called "vertical". This "thought" is such that when one constructs a schema, this schema and all its consequences are in place with it; it is the so-called "rapid" thought of the American Indians.

The instant is not a point on the mathematical representation of time which is that of the straight line  $R$  of the real numbers; it is not this point of this line which can be considered as a time interval  $\Delta t$  tending towards 0. The instant is not placed on  $R$ !  $R$  emerges from the moment. In a sense, the instant is more eternal than time which, the time of clocks, will never contain eternity.

The concept of eternity is interesting because it indicates much more than an unlimited time scale; it indicates that but also a state, a state about which any measurement is permitted but does not satisfy.

Consistency will not be defined. It is admitted because deeply felt. It is not measurable, it is not existence in a place; it is only a face on cerebral constructions, on objects, systems of objects. It is a subtle combination of face and memory <sup>4</sup>.

Coherence is existence; we can add the field character to it even though there is no domain where to place it. But as in poetry, in literature, expressions are taken from contexts and transported into other contexts; this process thereafter will be called: transport of structure. Thus the concept of field, by transport of structure, of extension in the usual sense will approach that of depth, but to this depth will not be added a new dimension.

The fields of coherence, which will be presented in this course, are established first by necessity, then by the aesthetics of the human spirit which they reveal and oblige to reveal by multiple, changing, wandering structures which they marry, energize.

<sup>4</sup> We will see more and more that combinations of terms and expressions from the usual C. de C. make it possible to escape the usual C. de C..

To succeed in this it was necessary to set up new concepts by unusual constructions and arrangements in the usual thinking between the concepts, the constructions themselves often being concepts. All this makes it possible to escape from the usual (or rational) Field of Coherence (C. of C.) to build another field of coherence (O Other Field of Coherence). There will only be two C. de C..

This expression Field of Coherence was imagined by Bernard Vivès.

The C. de C. were presented at the Institute of Physics in Bern as well as at the Academy of Sciences in Paris (1960). B. Vivès worked from 1964 to 1968 at NASA in a team of eight people. The C. de C. theory has been clarified by these researchers; they came to think of the planets as balls of wool, geometrically rolled up ribbons. Thus the spherical appearance was sometimes preserved but we had more to do with formless magmas. B. Vivès uses what he calls "Extensible Calculus" which is expressed in so-called "extensible" functions and these, thanks to their folds, fit into a model which, for example, attempts to explain the succession in the time of two genera of vertebrates without there being any link between them.

The extensible calculus prefers to forget any notion relating to geometries to stick to the idea of a break in the plane <sup>5</sup>.

We will not pursue this path any further, which must have been fruitful but which has remained totally ignored for military reasons, for the stability of the usual teaching of crowds, and for the safeguard of physics in which we must not

<sup>5</sup> B. Vivès, when he established the Coherence Fields theory, envisaged two such fields, or even many more. In the theory which will not be described in this booklet and which V. Rosgnilk [4] has already outlined, there will always be only two. The expression Field of Coherence will therefore have a different meaning from that of Vives. Like Vives, the theory will have a mathematical structure and a physical meaning. But both the mathematical formulation and the physical model are different from what has been deposited at the Institute of Physics in Bern and at the Academy of Sciences in Paris. Vivès had developed what he called the "subdifferentiated lattice theory"; the lattice structure is well known in mathematics but he elaborated lattices with special properties which he cataloged as subdifferentiated.

As for the theory presented here, it is based on a notion of wandering with a function of wandering (which Vivès also used) then involves the flight of reference points and then, non-Euclidean geometries in order to describe paths of points wanderers. [4] and [7]

touch on the principle of conservation of energy and the second law of thermodynamics. It should not be forgotten that with rational thought, an economy has been set up and attached which muzzles human beings to make the best use of them and to make them act in very specific ways and goals. Money handling is stable only by accumulating financial transactions. They seem to possess a dynamism. Indeed there is one, but that is only an aping of what we will present of the dynamism linked to the Other C. of C.. The stability of a power of money holds only through tentacular effects and repetitive. Faced with this, we are implementing the concept of "Hard Core". It's a form, it's a self-amplifying system. He does not draw from his exterior; it draws from itself by processes which make it possible to say that the hard core is pregnant for certain of its properties. These properties will be considered later. They are not placed in a rational description of the world.

We are putting in place, little by little, an approach that will establish constructions between concepts; we would like to point out that these compositions between concepts may seem strange in the sense that they give rise to other concepts that have nothing to do with the components. This is very important and should not discourage the reader. Moreover, if we observe well, in everyday conversation, comparisons which are insertions taken in themselves, having nothing to do with the ideas considered but simply by their structure, rhythm, are very often used. Metaphor is found in poetry; we will use its construction but it is also very present in everyday language.

In the rational world, we find our way and behave thanks to what we call landmarks, units and the transport of these units.

Thus are set up units of length, area, volume, time, units of force, electric current intensity, electric voltage, magnetic field flow, hydraulic current flow, etc. the units are legion. These and their

transport which is carried out by the operations: addition <sup>6</sup>, multiplication make it possible to describe and evolve in what we call the “Local”.

The room seems to be the same for everyone, which seems to reinforce its stability. This stability of the local is at the same time a trap because the elaboration of the coherence which intervenes in its installation is continual; the language attached to the rational world is extraordinarily precise, which facilitates division and thus gives complete freedom to analysis.

We will postulate existence without landmarks. This will be the Global. Existence without landmarks will make it possible to attach to the Global what is not identifiable. Forms, such as we are going to consider them, will for some be linked to the global but will not be in the global, which would imply a relationship of belonging, container and content, set and element. The global is not made up of elements, it is existence without landmarks. He is an evocation. It is both evocation and existence. These are linked in a certain way which is not a tension.

The global is by the fact that everything that is not identifiable is linked to it.

Consider the notion of Love; we know that love is not measurable, not identifiable, we cannot place any unity on such a concept. Love exists but cannot be located; it is linked to the global. It is the same for the concepts of suffering, fear etc. Some of these sensations support a relation of partial order (greater fear than..., greater suffering than...), partial because one cannot compare on a whole scale. Moreover, the imposed scale is not stable. Atrocious suffering cannot be compared for the same individual and it is impossible to want to compare suffering between individuals. Pains can, in certain cases, be comparable, one will say support a scale of value, but this “intensity” of the pain, in the extreme cases, does not exist any more; the ladder becomes unstable.

So these attempts to map scales associated with localized concepts dilute the scales. The pain, the suffering is not entirely localized, shall we say.

<sup>6</sup> Operations are an expression of the transportation of units.

It may be argued that some concepts are subjective and others are objective; this is right in the language of the rationalists. As for us, we will never use these two terms for the following reason: words carry within them the intentions that have contributed to their elaboration, to their establishment in language and to the evolution of language. This is what the rationalist too easily forgets, who in this way of thinking has frozen the word too much, above all has frozen his own appreciation of the word.

Thus using the words "objective" and "subjective" will immediately lead to a return to the rational C. de C.. And one must be convinced that removing certain words from one's language is not an operation of impoverishment but that, on the contrary, this caution is one of the necessities to get out of usual thought and to build a dynamic thought <sup>7 8</sup>.

Words have their power, their density and impose a direction in the implementation and expression of an idea. We must not forget the tacit knowledge, and the words are impregnated with it, at least some.

The Global, for so-called Bourbakist mathematics, has no meaning because in what we very often consider, the set and the element are impossible to distinguish. They

Q

will be able to place themselves in "dynamic duality" in the Yin-Yang sense of the expression, that is to say that there will be neither whole nor element and both together and element <sup>9</sup>. But keeping this point of view is constraining; it is necessary to consider another involving internal dynamics. Then the word becomes a sign which will evolve and then the word will be able to possess what we call a "Nébulaire" [4] (volume 1).

Note that this nebular word was imagined from the word nebulosity and this with the aim of evoking. Evoking is the beginning of a path in thought, of a cerebral construction; one can remain with the evocation for that to which one is addressed; the evocation will develop in itself in a path or as a construction.

<sup>7</sup> Certain words, in this case these two, used in descriptive developments of states, situations, cerebral constructions, will bring these states, situations, constructions back to usual thought. This will cause us to approach non-rational phenomena by the usual way of thinking which is not adapted to them.

<sup>8</sup> What we will see later.

<sup>9</sup> This is a way of expressing in rational thought a concept that is not there. Naturally in rational thought this pictorial representation can be considered as a popularized approach. This is not a problem since this thought cannot assimilate this concept.

We will see later that there is not a single room, but several “rooms”; that a room can be imperfect, with breakages; there are such cracks in the local set up and explored <sup>10 11</sup> by rational thought.

We set up the local and the global; the local emerges from the global or is immersed in the global <sup>11</sup> by what we have called with B. Vivès the shifts and by the concept of the cumulative.

Then recently the concept of “Idatheme” was clarified, created around the years 1984-1985. The Idathema is a third type of existence, absolutely impossible for the human mind to represent.

We saw :

- Existence with landmarks: the Local, one of the different “locals”.
- Existence without landmarks: the Global

We now have another existence:

- The Idatheme

As for the Global, we will say of a form that it is linked to the idatheme. Forms, places, acts, intentions are linked to the global or to the idatheme or to both simultaneously.

It is easy to imagine existence without landmarks. On the other hand, the existence of the idatheme is more difficult to assimilate. We are going to give some examples of concepts, places, forms linked to the idatheme.

- certain constellations.
- Characters of Easter Island script.
- Curves like the cycloid, the tractrix.
- All the statues of Easter Island; on the other hand, a statue alone is not linked to the idathema.

<sup>10</sup> (Note from Anne-Marie Branca): "set up" and "explored" are to be taken simultaneously. But when we reason in this way, we are no longer in the usual way of thinking. Such “comparison” between an expression and a word makes it possible to escape the usual C. de C..

<sup>11</sup> The term “immersion” was chosen by Marc Beigbeder (private communication to J. Ravatin).

- If a human being stands behind such a statue, it becomes linked to the idathem and so does he.
- If a form like an egg is made to traverse the labyrinth of the Cathedral of Chartres, it becomes linked to the idathème whereas the egg form is not, and it remains so after the course. If one goes to look for an egg on a rock - a celebration celebrated once a year by the Easter Islanders - emerging from the sea and brought back, the egg is linked to the idathema.
- The fog is linked to the idathema; clouds can be.
- The mandrake is linked to the idathema; if you dip it in cold or hot water, it disappears; ditto if we grind it.
- The Philosopher's Stone is related to the idathema.
- Arcadia: name of a valley in Greece where men met the gods, is linked to the idathema.

Often the forms which are linked to the idathema emit avaecum, certain eifs like VC, FV and also yews.

But the black madonnas, while being linked to the idathema, emit nothing of what we have just pointed out; they begin to emit if we pray in front of them.

- The device of Georges Claude and Coutelen is linked to the idathème.
- The device of Léon and Marie-Thérèse Sprink, those of Louis Boutard are not linked  
12 to the idathema.
- The devices of JW Keely, of Th .Moray are related to the idathema .
- Loch Ness Monsters.
- The Yeti.
- The great sea serpents.
- The animals drawn on the Nazca tracks are linked to the idathem.
- The magic squares, the Sator square, are linked to the idathem.

<sup>12</sup> See [4] and [7],

- The Château de Montségur was linked to the idathème but is no longer so.
- The Ark of the Covenant was linked to the idatheme.
- The DNA double helix, a beaded dodecahedron are related to the idathem. If we add a central ball to the pearl dodecahedron, we detect the 22 arkkhams. Moreover this one, when it is carried out, acts on all those without central ball and makes that they emit all the arkhams. It is the presence of such a beaded dodecahedron with central ball that results in properties on the others. This existence does not need neighbors.
- Water circulating in a half-pseudo-sphere is related to the idathema; if we replace a half-pseudo-sphere by a hyperboloid, this does not happen [9]. Victor Schauburger had chosen a hyperboloid; for that he had started from the work of Kepler.
- Egg white and other colloids are related to idathema.
- The gummy water of Louis Boutard, the viscous water of Wilhelm Reich are linked to the idathème.
- The dolmens, the alignments of Carnac, the cromlechs are linked to the idathème. A menhir alone is not linked to the idatheme.
- A very large animal or human figure drawn on the ground is linked to the idathem. Such designs are particularly found in the English countryside.
- Boves and Nouraghes <sup>13</sup> are linked to the idatheme; when you get in, you take the properties and when you get out, you keep them for around 4 to 4.5 hours. This allowed, by doing rituals in these places, to direct the ritual, to amplify it.

<sup>13</sup> Boves: Nicolas Germain [8] did a search to try to identify the word bove; he remarks that this word is not found in the usual dictionaries, but that the "Etymological Dauzat" of 1938 gives the following details: Bove: regional word already known in the 12th century by Guillaume de Tyr - Historian of the Crusaders - means cave, rear -cellar. Bove would come from the combination of two words:

(1) Gove - it would come from the Germanic Gaupa meaning hollow of the hand - it is the Cauchois word for the cave.

(2) Baume - it would come from the Gallic Balma in the 8th century - cave of the hermit -.

Many of these Boves are listed in the work of Maurice Broëns [10] - Honorary President of the French Society for the Study of Undergrounds. He describes in his book [10] the unusual works existing in Europe: tumuli, underground structures of which the boves are part.

The most beautiful bove is in France in Neuville-sur-Touque, in the Pays d'Auge, in Normandy. It is on the so-called Jaunière property; this property was purchased in 1935 by Dr. Robert Chaudet-.../...

The idatheme is an existence that is not linked to the global, it is characterized by the fact that it is "to be being". This to be understood must be thought of as a whole, without being broken down.

Now consider Idatheme, Global, Local as well as Soul, Spirit, Body. We have two sets of 3 elements each. In general there is no correspondence by their characters between them (one can of course impose correspondences by mathematical applications, but these are done a posteriori; in certain cases they transport properties of a set in the 'other'). Here the correspondence exists by what one feels on the trio: soul, spirit, body; what religions present but do not explain, which has given rise to multiple uses of these three terms depending on the contexts in which they are immersed.

While here, we immediately feel the correspondence:

Soul --> Idatheme

Spirit --> Global

Body --> Local

now deceased - and his wife. He immediately visited the bove but at that time it was more complete than now, because collapses occurred.

She had a stone table - seen by Commander Mouton - which was destroyed by vandals. This is the reason why the owners prohibit access; nevertheless, it is not only vandals who are dangerous in such places; archaeologists who absolutely want to restore for the good conservation of the place, not understanding what these artificial caves could have been used for, risk distorting the signs or shapes engraved in hollow or appearing in relief. For many of these researchers from the CNRS and elsewhere, the boves are troglodyte dwellings - they scratch, dig to find traces of hearths, tombs and they scratch again; and so they claim that the boves are food granaries, refuges during the French revolution, arms caches during wars.

The Neuville-sur-Touque bove is surmounted by a wood which may have been cleared - 4000 to 6000 years ago - when the bove was in use. Circles of earth, concentric appear in the wood. They could amplify certain effects triggered in the bove during powerful rituals.

These rituals were to last for a long time. They awakened in particular the "Chthonian Forces" (these will not be described in this booklet). Ceremonies, in the open air, above the bove, could take place during the full moon [4],

Graffiti on the threshold of the bove served to block the establishment of certain harmful states, or to purify the officiants as soon as they entered the place [4]. In the boves the rituals were certainly very long in order to trigger the phenomenon. It probably took several people, who succeeded each other day and night, so that the bove was never empty and who all the while, worked to obtain the information requested; these depended on local folklore and the era.

Nouraghes: they are fully described in a book by F. Niel [10]; they are alone or in groups. They are found in Sardinia.

When we speak of the body, it is the localized being that we are considering. So he is in the room. The mind is completely delocalized; it is linked to the global. The soul, on the other hand, is linked to the idathema; it is "being being". To verify this correspondence by tests, you must follow the above procedure, otherwise nothing will be found. This approach is the equivalent of a detection device [5].

**Erratum:**

For the sentence of Johannes Wolfgang Goethe quoted in booklet 3 of the second level, it should read: "We wishes are the presentiments of the faculties which lie within us, harbingers of what we will be able to accomplish"

## Chapter VI

### */ . Digression on the expression "Rupture of compensated forces"*

We find this expression in a certain number of books where it is a question of forms.

The “rupture of compensated forces” would be an imbalance between the “cosmic” and the “telluric”.

First, there are two meanings to the expression “telluric currents”.

- The rational meaning : it is electric currents in the ground due to differences in soil moisture or different types of rocks that create ions. These currents can manifest themselves over very long distances.
- The esoteric meaning : it is sometimes eifs sometimes eims - E for emergence, I for influence and M for mass: discovery of P. de Montgrand; eims are different from eifs; they will not be presented in this booklet -.

There is also what is called the "Wyvern" obtained from eims sent for example on a cylinder of twisted wood. The wyvern is composed of makhras which are 56 in number and completely different from the eifs or the eims.

Let us note that in the phenomenon primes with the rupture of compensated forces, one does not know if it is about telluric currents in the rational sense or in the esoteric sense or even the mixture of both.

We are now going to set up a concept which will make it possible to present this phenomenon not linked to “forces” but to a property of space.

Broken symmetry : the concept of broken symmetry was first introduced in physics: theory of elementary particles and also in crystallography, but it gradually spread to other areas of physics. For this we consider a symmetry group in which a phenomenon,

a situation are invariant. A situation can in the course of evolution only satisfy a subgroup of symmetry of the group of origin. In this case we say that for this situation there has been a symmetry breaking.

We have a broken symmetry when an asymmetry appears, putting Curie's principle in default in a physical phenomenon. In some cases, it comes from the dissymmetry of physical laws (eg violation of P in the disintegration of the K meson into pions); in other cases (crystallization, appearance of turbulence).

Let us consider the path: Physical system  $\xrightarrow{\text{Y}} \text{breaking of the symmetry of this physical system}$  and consider the scheme already used: A certain concept  $\xrightarrow{\text{TM}}$  Space of the usual C. of C. That is- i.e. by the inverse operation - that we will write (way)<sup>1</sup> -

A certain concept  $\xleftarrow{\text{X}}$  Space of the usual C. of C.

This concept will be named for convenience of expression Space before the break is Es Av (for Space Before).

Thus EsAv  $\xleftarrow{\text{l}}$  Space

There are shapes that allow to pass from Space to Esav and also these shapes allow to consider a new type of shapes that we will call the shapes before breaking: Esav-Form.

In the couple man-woman, the difference between the man (M) and the woman (F) comes from the way above.

We can go up by (path)<sup>1</sup> acting on {H, F} and we obtain the entity before the break.

(way)<sup>4</sup> (the water entity) provides access to a very interesting entity. We can think of the "waters above" of the Bible.

The "rupture of the compensated forces" corresponds to a region where we can go back to the Esav. This is very interesting but it is necessary to know how to use this region.

So in the terminology of the waveformists <sup>1</sup> there were these regions in imbalance between cosmic effects and telluric effects; this, again for them, leads to the detection of a V' in the ground.

Some designs from our ancestors :

We are not going to go into all that archeology and architecture have left as evidence of our predecessors; but only to attach ourselves to these few characteristic milestones which are the menhirs, the dolmens, the pyramids.

Perhaps they will facilitate our journey, even if it is not obvious at first sight and even then...

a) the menhir

This vertical stone, erected in prehistoric times, was not erected to embellish the landscape - one might think so - but with a view to fulfilling a function that the rational world no longer knows and is unable to apprehend.

If we examine the rooting of a menhir in place, with a pendulum or rod, we realize that this monument is very often linked to telluric emissions. But which ones?

We then detect eifs or eims, with which states are sometimes associated.

If these are harmful and the states also, they will have to be removed to preserve both physical and moral health.

The menhir is interesting in this case to rebalance the place. What is very important is that the "force breaks" are the diagram of a possibility of using the Esav. A person who is on one of the lines of "breaking of force" is found to be a form before the breaking, an esav-form.

<sup>1</sup> For those who deal with "waves of forms".

Many such systems now no longer work. It should not be deduced that for all the menhirs planted vertically there is the possibility of passing to esav-forms. Moreover the alignments of menhir do not have this property

Exercise 1 : We need two operators.

- One rotates its pendulum vertically along a line of Esav of form - called line of esav -.
- The other walks around the near vicinity, letting his thumb and forefinger take a wooden broomstick held from above.

Check :

- 1) that if the + of the handle is up, the pendulum of the first operator will not stop.
- 2) that if the — of the stick is at the top, there is a chance that a position on the ground of the vertical stick will cause the pendulum of the 1<sup>st</sup> operator to stop.

Then locate the place.

Check :

- 3) that the handle held vertically is on the vertical of the bisector of the angle of 2 concurrent lines of esav.

It is recommended to have explored the surroundings so as to be sure that the lines of esav have been detected beforehand.

Consequence : The broomstick is replaced by a very small menhir weighing a few kilograms.

Check that this stone has only 2 polarities and that they are + for one and - for the other.

Place the stone in such a way that the + polarity is at the bottom and the - polarity at the top.

The line joining the polarities being vertical; you have to arrange for the shape of the stone to achieve this by giving the impression that the stone itself is vertical.

This vertical must pass through the interior bisector of the angle formed by the 2 concurrent lines of esav.

The stone should have a wedged base, but not buried, however slightly.

Notes :

- 1) if we consider that the menhirs are linked by their position to the lines of esav, it is necessary to clear their base if it is no longer so and perhaps straighten them.

But all the menhirs do not correspond to 2 such lines and their raison d'être was perhaps to use the lines of esav or else quite something else.

- 2) When the menhir is placed in this way, the lines of esav are destroyed unless a human being stands upright, on the interior bisector of the 2 lines and far enough from the menhir.
- 3) At the test lines we detected V'E- We are therefore in an unhealthy place.

Indeed the V'E is quite harmful but perhaps it was used for beneficial purposes by the Ancients?

- 4) Is the menhir a stone of fertility intended to make crops and animals prosper?
- 5) Or has the stone acquired special properties like some of them which seem polished by force, perhaps, by the bellies of sterile women?
- 6) Or was there a network of menhirs with functions determined by their respective geographical positions?

New results about the menhirs : the menhirs can be considered as awaiting use. That is to say that under certain conditions: rituals, arrangement of forms - even human - in the vicinity of the menhir, one can generate special fields - which are not of electromagnetic nature -, which we have discovered and which are called Z and ZD fields. They seem localized.

The applications of these fields are multiple: by acting on these forms one generates eifs, but also the "universal currents" of Louis Rota - Italian researcher who worked in France and built devices for medical application -

We must always bear in mind that the Ancients did not think like us and did not see the same world as the one in which we live. They needed to be more aware that they were building the world. They were much more flexible in the face of unforeseen situations. They lived close to the brain mechanism which is wandering-unexpected-wandering-unexpected-wandering...

b) the dolmen :

Here the stone is a horizontal table supported under tension by vertical pillars so as to provide a covered cavity underneath.

Observation of the dolmens and covered walkways leads to the following remark: they are oriented East-West. In addition, a crossing of esav lines is detected near the eastern end of the dolmenic table. One of the 2 East-West lines follows the main axis of the table, the other, North-South, is perpendicular to it.

Exercise : Drill the ends of a plank in naturally polarized wood on supports of the same height so that the plank is horizontal.

Make a picture of the intersection of the lines of esav by drawing two perpendicular straight lines on a card - card stock -, by piercing the intersection with a cookie cutter and turning the card over so that the lines are underneath.

- 1) Move this upturned cardboard under the board. At any position, the + of the board emits the life node. Check it.
- 2) Also check that there is a position of the cardboard under the board that makes this emission of the life node vertical.
- 3) by specifying the location by repeating the operations and by fixing the eif using a small copper ring placed on the board, we see that this point is 8/10 of the length of the board, going from the + from the latter to -.
- 4) Note that the eif  $V^E$  of the cardboard is transformed into  $V^+E$ .

Consequence : can we rebalance ourselves by lying on the table of a dolmen or by staying lying or squatting inside? - assuming that there are still functional dolmens today -. In part, yes! But if we have a weak ext, he will remain so.

Other Considerations :

- 1) As for the raison d'être of the monument, it remains in the conjectural domain. This does not prevent admiring in passing this technique and these technicians who brought a precise point of a stone weighing tons or even tens of tons vertically from another point.

just as precise. Finally it is that we find from the preceding considerations on the forms.

When we are in the dolmen, we detect the esav. That is to say that we go back to the richness of esavforms.

Naturally the people of those times knew how to use their concepts because of their type of thinking. We can then think of the extension of a physical property towards a religious or magical objective; it should be remembered that for the Ancients - and they are part of it - there was no division as in

rational thought, and religion, science, philosophy, morality, art constituted one and the same entity.

2) The 8/10 received their verification by making a very simple atmosphere rebalancer of remarkable efficiency. All you have to do is drill a hole from side to side at 8/10 of the length of the axis of a board and orient it - hole towards the east - at  $85^\circ$  magnetic. A V E IS THUS ELIMINATED ; the larger the board, the denser its wood, the more V'E IS ELIMINATED FROM IT. This can also make it possible to put back in its place a polarized body which has rotated  $180^\circ$ . But we will not systematically remove states like |K Sh Ph with reversed Sh>.

c) The pyramid structure

It has given rise to many books and commentaries, especially in its realization which is that of Cheops. It is still the class of pyramids with a square base and an axis of symmetry confused with the height because one can imagine multitudes of pyramidal shapes.

Another very interesting shape to study is the cone and even the double cone which is the rhombus. The Ancients, Egyptians, Hebrews, placed the rhombus in some of their ritual apparatus. We will see this later in this course - we must refer to the work of Louis Boutard -.

Let's see some development on the pyramid of Cheops.

- The Pyramid of Cheops

It is useless to dwell on a monument which has given rise to so many books, articles and discussions. Let's get back to basics.

The dimensions, according to recent data, are as follows:

230.36m. < base length < 230.40 m.

height: 146.60 m.

The measurements are precise enough to measure an apothem of 186.44 m.

Taking the half base as unity, we have:

$$\frac{\text{Apothem } 186.44}{\text{Half base } 115.19} = \frac{p}{1} \approx 1.6185 - 1.618 - G$$

$$\frac{\text{Height } 146.60}{\text{Half base } 115.19} = \frac{h}{1} \approx 1.2726 - V \text{ CD} - 1.2716$$

We can reasonably admit that the pyramid of Cheops was built according to the Golden Number ( $p$ ), which, reduced to a half base unit, gives:

$$\text{Base} = 2 \text{ Apothem} = (p \text{ Height} = \sqrt{T}(p$$

Here we are therefore faced with the Golden Number ( $p$ ) and not the Radiant Number  $\sqrt{J}$ . Yet we feel  $\sqrt{J}$  greater than ( $p$ ); firstly because the forms constructed with  $\sqrt{J}$  do not correspond to  $|K \text{ Sh Ph}$  with inverted  $\text{Sh} >$  whereas it is often the case with ( $p$  - see the lesson of the 1<sup>st</sup> level in which it was pointed out that ( $p$  intervenes on fixed forms, which can nevertheless be alive (continuation of Fibonacci whose first terms are related to the growth of plants), and which intervenes rather for forms in movement. Moreover in a certain number of forms where one found ( $p$ ), G. Cordonnier, the discoverer of  $\sqrt{J}$ , has verified that we also found  $\sqrt{J}$ . Note that this is not the case for the Cheops pyramid.

The pyramid of Cheops is actually a truncated pyramid: the dimensions given above correspond to the truncated pyramid and not to the pyramid, which leads to some errors in the results of the calculations.

Orientation is key. This pyramid has its faces perpendicular to the cardinal planes.

#### • Digression on Gizeh

Giza is the current name of the huge necropolis of ancient Letopolis (now Cairo). It extends over a plateau, leveled by man 4,500 years ago, with an escarpment on the south-east side descending 40 meters below. At the foot of this plateau once ran a channel of the Nile separating the desert area from the fertile land.

The main monuments are:

- The Sphinx
- The Great Pyramids - one of the seven wonders of the world, the other six were:
  - The Lighthouse of Alexandria in Egypt,
  - The Mausoleum of Halicarnassus,
  - The Temple of Artemis at Ephesus;
  - The Colossus of Rhode;
  - The Hanging Gardens of Babylon;
  - The statue of Jupiter of Phaedias in the Temple of Olympus.

The pyramids are placed diagonally from northeast to southwest, so that no one ever blocks the sun from the others. In the field of shapes, shadows have amazing properties. They can sometimes be colored as Goethe pointed out.

The first two pyramids are almost the same height at the top, because that of Chephren is lower but its base is higher. The three have their burial chamber in the rock, almost in the middle of the body of the construction. The pyramids of Cheops and Mykerinos have other superimposed chambers. All have their complete monumental ensemble: funerary temple upstream, communication gallery and temple downstream; Chephren is the best preserved.

Chephren and Mykerinos have three satellite pyramids, Chephren probably only had one. The sacred boats buried around the temples above Cheops and Chephren were perhaps numerous.

But despite the rooms, the corridors, they are almost full. And it is this "almost full" that allowed us to discover what we presented in the 1<sup>st</sup> level course and that we called F Ext.

Exercise :

Check that a  
Cheops-like pyramid, oriented in this  
way with respect to the  
NM emits the escape of the C. of T..

It also emits much  
more.

Note that OABCD is the first

- The Cheops pyramid (continued)

The true pyramid of Cheops gives V at the top and I'UVIE at the base. By connecting it to a disk or square emitter, it causes a 180° rotation of the polarized body.

These inversions may surprise and what we know of Egyptian beliefs is not enough to explain.

It is difficult to invoke the following argument: the Egyptians believed that the survival of the dead required the preservation of his body, hence the mummification obtained, not only with

chemical preparations, but also by a set of processes which reverse the decomposition process, in particular by the rotation of the polarized body, by the VE which is detected at 1/3 of the height of the pyramid starting from the bottom.

It is classic to mummify a third of the height of a cardboard or plywood pyramid; it must be oriented like that of Cheops but you have to pay attention to the neighborhood; this orientation is sometimes to be modified. In addition, people complain of not getting the desired effect on their piece of meat. This is due to the neighborhood; they place the pyramid on a table with a drawer, above the drawer, or on a bookcase with compartments. It changes everything! We no longer have the V'E which removes the water from the meat.

In the case of good orientation and good neighborhood, the case of the almost empty pyramid is not like that of Cheops which is almost full.

In a cardboard or plywood pyramid, there is no UVIE at the base and V'E at the top.

On the other hand, we always find the V'E at  $\frac{1}{3}$  of the height starting from the base.

Let's use some concepts that will be presented at the end of this booklet:

The pyramid of Cheops, at a third of its height, has a decalaire. This is not the case of an almost empty pyramid. On the other hand, the latter has a channel at a third of its height.

Shift and channel are indices of possibilities of delocalization or localization.

Here we must pay attention to the language used. At the third of the height starting from the base, we detect shift or channel but the  $\frac{1}{3}$  of the height is precise whereas shift and channel link globally.

This comes from the fact that we use the language of the usual C. de C. but that we relate to concepts of the Other C. de C..

We can consider the Egyptian plastic following the presentation of the architect Fournier des Corats in his book "The Egyptian Proportion or the reports of divine harmony". He was using the .9...

folding of the faces of the pyramid on the base square. He finds 8 ratios where the Golden ratio intervenes.

He analyzes Egyptian monuments, sculptures, paintings and easily incorporates them into these reports.

<sup>2</sup> Vega Editions.

At first glance, this is not surprising when you know the conventional and stereotyped aspect of Egyptian art. There does not seem to be any error with respect to the bases of the proportions.

Naturally, one might think that the observed inversions of eifs cast doubt on whether we are on the right path.

This remark is something to be wary of. One cannot make of an inversion of a spectrum of eifs a dogma of harmfulness. We simply observe the inversion. Spectra at the EFF level come from analogies with a wave system; we have left this analogy aside to substitute an axiomatization for it. This one, although it does not explain the historical approach, say the heuristic aspect, cannot erase this aspect which gave birth to the classification of the eifs, their distribution on the square or disc transmitters.

It must be understood that the arrangement of events is a process of creating what was called "waves of forms" and that "waves of forms" - now eifs - are the progenitor (G) of the series of events.

The sequence of events is a primer (A). We are thus faced with a system  $\{A, G\}$ .

Let's see before going further a new concept: the Equimsey.

#### d) The Equimsey

This is an entirely new concept in human thought. Consider two forms F and F'.

F and F' will be said in equimsey (and we will write F IF') when they are linked to a third form by a trajectory - We have either F I F' or F' I F -.

Take the Earth in its orbit; at the time of the equinoxes, it is in positions T and T' respectively in spring and autumn. The earth T when it is in T or in T' is in equimsey. Thus  $T(\text{in } T) = TIT'$  and  $T(\text{in } T') = TIT'$ .

This is detected as soon as one becomes aware of what equimsey is. And if the Earth is not in T or in T there is no equimsey. It is for these positions that the duration of the day is equal to that of the night.

Or will say either the earth T is in equimsey, that is to say that T is Tl T' or that T and T' are in equimsey. The same word signifies either a state or a tension between two forms.

In this case the curve is the portion of the helix - which is often reduced to the plane curve: the ellipse, by simplification - that the earth travels in one year.

In the field of forms, the equimsey will often intervene. It is completely out of the usual C. de C..

Let us consider in physics the system constituted by an object and its image obtained by reflection in a plane mirror.

Let us now apply the process - already used in the course of the <sup>st</sup> level - called: transport of structure. We have seen that the concept of path is used for this.

object --T-Q1Ç-->image (by symmetry with respect to a plane)

Let's go back to this path that we apply to a form of the usual C. de C.; this will bring into existence the concept of the image of a being.

Let us take the observer on which we make this channel act.

the observer ---<sup>TM</sup>----->image of the observer

But let's look at something more general.

We are not going to consider the observer in the sense of physics, that is to say a human being linked to a system of reference points, but a human being representing himself doing operations of the kind of displacement in space, giving himself states , speaking to himself or to other people, finally more generally the observer thinking and looking at himself thinking. This will constitute what we call the OBS.

Thus the obs is the observer thinking himself thinking.

Let us now consider the obs — the way. We <sub>will</sub> call this result the image of the obs.

We will therefore have Obs --> the image of the obs.

Of course the obs is little in the usual C. de C.; as for the Image of the obs, it is linked to the global.

#### Fields of Consciousness :

Consider obs|Image of the obs: this equimsey is the consciousness of the obs.

We talked about equimsey; however, the curve to which the two terms are attached has not been specified: obs and image of the obs.

It can be any curve, continuous, discontinuous, closed or not, of a fractal object... And by the fractal dimension which is, in general, not whole, we will enter the domain of surfaces, volumes, then vector spaces, affine spaces, Euclidean, Riemanian, projective geometries.

Thus for each curve, each plane, more generally for each mathematical structure mentioned above, we will have a “Face of the field of consciousness”.

We thus arrived at the concept of Field of Consciousness, which is completely different from the Field of Coherence.

The obs can extend the concept of consciousness to other human beings who are placed in its field of coherence (C. of C.) but it will always only be an extension of consciousness.

Consciousness now presents itself as a notion linked to the global, therefore as a notion which is not in the usual C. of C. but which belongs to the other C. of C.; it is in this like love, fidelity. These are concepts on which no scale of measurement can be imposed.

This does not mean that all the other C. of C. is composed of notions without landmarks. In the other C. of C. we will find what we call Rays of Coherence (R. of C.) and Swarms of Coherence; in all these there will be “local” which is not the local of the usual C. de C..

More precisely, when we have the impression of finding concepts linked to the global in our C. de C., it will be a "trace" of the other C. de C. in the usual C. de C. .

Consciousness as it is envisaged by psychologists is a deformation of the concept of consciousness as we have just established it. Their concept of consciousness is distorted to accommodate the increasingly intense localizations.

By immersing the consciousness as a trace in the concept of field and by diluting this notion, one thus correctly constructs the “Field of Consciousness”.

c) The Cheops pyramid (continued)

A and GJA primer are in equimsey |G progenitor That is to say that we have: A|G.

It is the rational vision which, through a representation, gives the usual unfolding of events.

We would have the same thing in the following problem: it is that of the Extraterrestrials:

At some point we will discover extraterrestrials - it will not be the antics of beings linked to the UFO phenomenon. For the UFO phenomenon, we develop it in the work of Jacques Ravatin and Anne-Marie Branca: “Theory of Forms and Fields of Coherences (to be published by Editions du Cosmogone, during the year 1998).

So at some point extra-terrestrials will be discovered and this, we will say, in the usual C. de C., thanks to the discoveries of science; it will be consistent. In reality, scientific discoveries will have served as a ritual to discover extra-terrestrials; either A but the extra-terrestrials, themselves, are a partial localization of the world which engenders scientific discoveries, the evolution of humanity, or G. And again we have a system {A, GJ which will behave A| G.

We see little by little by these two examples, that the succession of events no longer presents itself as in the usual point of view and that it takes on a different character.

By thinking, let's bring the edges of the pyramid of Cheops into the cardinal planes - which amounts to rotating this pyramid by  $45^\circ$  - (we can also work on a model), the spectrum of the eifs will be distributed as follows:

UViE at the top

VE at the base

The equator becomes that of the tree trunk again.

This orientation was that of the Mesopotamian step pyramids on top of which a temple was to be built.

Editing left as an exercise :

Put on a table

- 1) an elongated, naturally polarized piece of wood.
- 2) a small model of a pyramid similar to that of Cheops with a plane of edges in the extension of the axis of the piece of wood and on the side of its positive end.
- 3) between pyramid and end of drink a copper or plastic ring placed on the pendulum so as not to find any more esav in the vicinity.

This little assembly can be used as a balancer. It can be made operational in a large volume by increasing the size of the various components. It will not intervene on harmful states.

Bélizal had attempted an association between the so-called Louksor shape - imagined by R. de Lafforest from the incorrectly called "Atlantean" ring -.

Belizal's error was to orient his pyramid like that of Cheops.

Otherwise we could get a pretty good rebalancer but only eifs.

Note : these assemblies are far, as a rebalancer, from the quality of what we proposed in exercise.

“Nature is a temple where living pillars sometimes let  
out confused words:  
Man passes through forests of symbols which observe him  
with familiar eyes. »

Charles Baudelaire  
(The evil flowers)

Charles Baudelaire: born in Paris on April 9, 1821. He studied well at the Royal College of Lyon, then at Louis-le-Grand, he knew the poets Ernest Prarond and Gustave Le Vavasseur. He made a 10 month trip to India. On his return he meets Jeanne Duval. Later he meets Théodore de Banville, Sainte-Beuve, Théophile Gautier.  
He writes “The Flowers of Evil”.  
He translates Edgar Poe.  
He died on August 31, 1867.

### 1. *Cumulative - Shifted*

Let's start with an example: that of the straight railway line, made up of two parallel rails and parallel sleepers. The crosspieces may have unequal, unknown widths.

Let's place an observer, seated between the rails, with prohibition to move and count the sleepers because it is his mission, to count the sleepers.

For him the two rails behave like Lobachevsky's parallels meeting on the horizon line at the point named, by people who use perspective: the vanishing point.

The observer - we can speak of an observer because here it is an observer in the sense of physics - knows that the number of sleepers is finite but he will never be able to know this number for the following reason: towards the horizon the sleepers seem to merge; and this from a certain moment and not from a certain number; hence the observer can no longer count them. As a result, he cannot even estimate approximately; it's not vagueness, it's absolutely indeterminate; we are in the presence of a "decalaire".

Note that the same is true if the railway line is curved towards the horizon.

Another case may arise; without reaching the horizon, due to the fact that the crosspieces are of unequal widths, it will no longer be possible to count, from a certain moment onwards, and the inaccuracies will be

impossible to remove. And yet we can recount, pass this range, but announce what number?

We are in the presence of a "cumulative".

When the impression of a sequence appears in a set of numbers and this sequence includes cumulatives and a decalar, we say that we are in the presence of a cumulo-declar.

Point Q responds to |K Sh Ph>

Note that in these drawings  
cumulatives and shifts have no  
no sharp or fuzzy boundaries. He  
we must speak of wandering.

In this  
cumulation  
another reality  
is set up.

An example of a shift can be found in the following old problem: the so-called "chicken and egg" problem. It is presented as follows: in evolution <sup>3</sup>, has it been the egg which has given birth to the hen or, conversely, has it been the hen which has given birth to the egg? In many congresses of scientists, in particular of biologists, this dilemma has been evoked many times seriously or as a joke, then it has been forgotten each time. Everyone was trying to lift the alternative.

This problem is interesting to present in the face of the points of view developed in this course because we are in the presence of a recursive system: egg - hen - egg... If we consider the rational point of view, we go up the following scale this simple recurrence punctuated by another scale; the 1-2 system <sup>4</sup>.

Note the Theory of Evolution.

We find ourselves in the typical case of a phenomenon described on a time scale of 10,000 years, 30,000 years, 100,000 years. We can even go back to the tertiary era because rational thought carries much more forward on this scale.

If we pose this egg-chicken problem according to the concepts developed here, which belong to the other C. of C. but which we will apply to the usual C. of C. to which we will give another representation by these new concepts - we imbue it with these concepts - the egg-chicken system emerges from a decalogue. Thus there is no hen created first laying an egg or egg first begetting a hen.

The usual C. of C. appears different according to the type of thought used; this leads to different representations. Thus, through these new concepts, the rational C. de C. appears closer to the other C. de C., less foreign. It is therefore necessary, when speaking of a C. de C., and especially of the usual C. de C., to signify the type of representation chosen to describe it.

<sup>3</sup> "The Theory of Evolution" is constructed from the usual time scale.

<sup>4</sup> The 1-2 system will generate the sequence 1,2, 1,2, 1...

Let us give ourselves a series of stakes, planted in the ground, protruding from the ground by a certain height; all these stakes are placed in the same plane. For an observer who stands up, placing these stakes in his gaze, and this for certain positions, these stakes appear on the landscape as perhaps preceding the landscape. The landscape and the series of stakes can create for this observer a decalaire which, as we said, is linked to the position of the observer. This could have been used by the Ancients to produce effects.

The writer Maurice Clavel gives a physical sensation of flight on a cumulative [1]. He writes: "Then it was lightning... Should I say lightning, if I heard nothing. But do those caught up in it hear its crash?... I'm not even sure I saw the flash. I was on the couch. I was lifted, thrown away, crushed. At least I had the feeling, but without any representation, as if everything happened in an indivisible time and space. I would be lying if I spoke of a transport and a distance... (\_\_\_\_) I have seen nothing but the night and heard nothing but the silence: a night, a silence distinct from all the others by the relation of the infinite to the finite. Two states mingled, without destroying each other, without even harming each other, which I recognized as bliss and terror. I even knew that it was a blow struck by the Father. Of what knowledge, I do not know. But I didn't completely lose consciousness, this detailed memory attests to that. And I even felt, as if there were also a duration, sunk indefinitely in this night and in this silence... (\_\_\_\_\_) And I don't think I'm boasting about a grace. Because it is one, certainly, but modest and current... ".

Maurice Clavel describes a feeling close to a cumulative. Some will consider it and classify it as what is commonly called, a loss of consciousness. There is indeed a disturbance of consciousness in the rational point of view of things, but in this real-life example, we can feel the imprecision of location which characterizes the approach of cumulo-decalaires. The description is explained after the fact, but the memory has kept the imprint of the flight from the usual landmarks.

The shifter passes from the local to the global, and reciprocally the global flows through the shifter. We cannot observe the global. It breaks, flows through the decalaires and cumulaires.

The forms which are in the usual place, according to the usual point of view, are immersed in the space-time structure. From what is developed above, we rethink the rational C. of C.; it is as seen from the outside.

### *IT Channel*

Another concept was necessary: it is that of *Canal*. The Channel is the passage from the local to the global and vice versa, but this passage is not made according to a counting scale.

The plural of canal is the usual plural or canals.

The channel is completely delocalized.

The term Décalaire was created by Bernard Vivès around the 1960s. J. Ravatin created a similar term at about the same time, without knowing B. Vivès: it is the word “Cumulaire”. marks. With the decalaire we are faced with a definitive escape from landmarks; in the case of the cumulative flight is followed by a catch-up of the benchmarks. Note that B. Vivès' definition of the decalaire was only of a mathematical nature. Now in our research work a very deep physical sense has been put in place but it is a question of physics which are not those of the rational C.de C.. It should also be known that the gravitational attraction of black holes resembles a flight of landmarks.

# I. Complements on pyramid shapes

We will use the folding of the triangles of faces of the Cheops pyramid on the square base.

Consider, for this, the base ABCD and the top S of the pyramid with AD = 2 and the height HS =  $\sqrt{\phi}$ .

Let us fold the edge AS on the diagonal AC, following AM.

$$AS = \sqrt{2 + \phi} \approx 1.902$$

$$AC = 2\sqrt{2} = 2.828...$$

$$\frac{AM}{AS} = \frac{1.902}{2.828} \approx 0.672$$

$$\frac{AM}{AC} = \frac{1.902}{2.828} \approx 0.672$$

$$\text{Gold} = 0.666...$$

The difference  $0.672 - 0.666 = 0.006$  which makes a relative error of  $\sim 8.928 \times 10^{-4} \approx 0.009$  or  $16/2$  0.9‰

For the Ancients such an error was negligible in the realization of forms even if it is a question of the Cheops pyramid to scale 1. Knowing the length of AS, it is easy to calculate AM by replacing the ratio 0.672 by 0.666. The fraction  $\frac{2}{3}$  (so  $\frac{1}{3}$  appears) will be very useful for the following

and we will see that we can take for 7C: 3.2; it will be very correct in the constructions.

Note :

One can wonder what relative error one can take to confuse lengths or on the contrary to say that to two lengths 1 and 1' correspond different forms F and F' as emissions, states, etc..

For this, consider the half-line of positive numbers that will serve us

- || scale to carry relative errors.

F F'

So in P we will have an error S

at P' we will have an error E'.

If we ask ourselves the question of knowing, by making S' tend towards S, for what value of S' the 2 forms F and F' can be considered as identical, we completely distort the phenomenon.

**P P'**

Here we find ourselves between P and P', not on the segment b —+ but there is a leak of the markers

between P and P' which is due to the very existence of the eifs associated with F and F'.

It is necessary to pay great attention to the stability of the scales according to the phenomena to which they refer.

Back to the pyramid : We can therefore very well build a pyramid whose edge is exactly 2 equal to the diagonal of the basic square.

The properties will not be altered in any way. Geometric constructions will be considerably simplified. Let's see a simple geometric construction to obtain the folding of the edge on the diagonal of the square.

Let's go back to square ABCD. Let us draw the line passing through the midpoints E and F of AD and BC respectively.

We get two equal rectangles with sides proportional to 2 and 1, what we call in traditional language “Silver Squares”.

The diagonal AC of the square intersects in M the diagonal DF of the rectangle EDCF

The 2 triangles AMB and CMF have their angles equal; they are therefore similar; this allows you to write:

$$\frac{AB}{FC} = \frac{AM}{FM} = \frac{2}{1},$$

### //. The Saying of the Companions

From the traditional tables of the Compagnons, we only know the “Said”. The word Table here means a closed planar shape. To return to the said, it is stated as follows:

“The Grail rests on 3 Tables of equal surface, one round, one square, one rectangular and their Number is twenty-one”.

“A fourth Table covers them and its Number is six”.

“The Grail is seventeen and he is one”.

It is both a mnemonic device and a symbolic text. So when we say: "The Grail is seventeen and it is one" we do not necessarily have to think 17 times a unit. Let's see an interpretation by J. de la Fôye. He assumed the Grail to be a Square Table and so he thought for its side: 7. Which gives diagonal  $\sqrt{98} \sim 9.9$ , graphically close to 10. Hence 10 and 7 is 10 - 7 (ten- seven). 10 instead of 9.9 is sufficient for a layout.

In this square, as we did for the undifferentiated and differentiated spectra emitting plate (EFF), we draw the inscribed equilateral triangles.

Let us orient the "Grail" with its diagonals NS and EO like the pyramid of Cheops.

Join the midpoints of the sides of the square with straight lines. We form rectangles, the diagonals of which we draw.

Each intersects a diagonal of the square at a point one-third the length of the half-diagonal from the center of symmetry of the square.

The intersections are the vertices of a square homothetic of the original square, the homothetic ratio is  $\frac{1}{3}$ .

#### Interpretation :

This square will be considered as the Square Table of Companions from which we will deduce the other two: the rectangular and the round.

A question arises for the Round Table: it is a circle whose center will be at the center of the square Table but in its surface intervenes  $\pi$  which is a transcendent number. But the Ancients only used whole or fractional numbers.

We will therefore use an approximate value of 71. Let us point out that later we will discuss this question of values of 71 in a remark.

We will be interested in the intersections of the Round and Square Tables and by symmetry a single intersection is enough.

So we are going to operate in redivision in two on the side of the Square Table - which perhaps justifies the number 21, that is to say 2 and 1-

But this number can just as easily derive its significance from the proportions of the rectangular Table as from the fundamental method of construction, or simply mean, as J. de la Fôye points out, that the Tables increase or decrease according to  $2^n$ . But let's go further

the Grail and the Tables can cover the plane from a center by homotheties of this center of ratio 3. The eifs that are emitted: VC, FV, and the 4 Ifs, then the Avaecum. Moreover, it is linked to the Idatheme as well as to the Global - All this as soon as the Table of the Grail has been considered as a new square Table of the Companions which will immediately involve the homothetics in this same report of the Round Tables and rectangular.

Let us point out that in the powers of 3,  $3^n$ , the larger n is, the larger the Tables are and the more the approximate value of 71 risks bringing a non-negligible error on the surface of the circle.

But starting from a circle with a fairly small radius, about 1 meter, we can make homotheties with a ratio of 3,  $3^2$ ,  $3^3$ ; these are enough, to generate a figure which will have remarkable properties although the circle of radius 27 m will have an area whose difference with the area where we would have taken 71, will not be negligible.

Let AB be the side of the square Table that we will take equal to 4.K midpoint of AD.

Take L such that KL = 1 on AD and OL =  $y/5$  then KO = 2.

The area of the square is 16.

Consider the circle of radius OL.

Its area is:  $71 \times 5 \sim 15.708$

Let's see the difference  $16 - 15.708 = 0.292$

What makes a relative error:  $\frac{0.292}{16} \times 100 = 1.825$

i.e. 1.86%

This is not negligible.

This also amounts to taking as the area of the circle  $71'R^2$  where  $71' = 3.2$ , which the Ancients could quite well consider: The relative error is: 1.87%.

If  $TIR^2$  (where R is the radius of the circle) = 16

With TT\_3.14, we get  $R \sim 2.257$  whereas we had taken  $R = y/5 \sim 2.236$  from which  $2.257 - 2.236 = 0.021$

For KL=4cm, it is acceptable.

The Three Tables

Draw a square MNPQ

Let S, T, U, V be the midpoints of the sides as in the figure.

Let's draw the STUV square

Let E, F, G, H be the midpoints of the sides of this square. This square will be considered as the Grail.

SF intersects EU at K. By symmetry around TV, K is on TV.

Let L be the symmetric of K.

From the homothety of center S and of ratio we get that  $KL = 2KO = \frac{MQ-TV}{3}$

So the perpendiculars to TV in KL intersect NQ in R and P such that  $MR = RP = PQ = \text{---}$

By rotation of  $90^\circ$  around O we obtain an equal division of MN.

By rotating  $90^\circ$ , we get I, H from K, L.

The figure HKIL is a dilation square of the square of the Grail, in a dilation of center O and of  
relation to  $\frac{1}{3}$

PL intersects SV in T. The KHT points are aligned by parallel projections which preserve the ratios.

We easily draw the Rectangular Table and the Circular Table taking into account the previous remark, ie for 71 we take 3.2 which on this scale is quite acceptable.

Let G be the midpoint of rectangle RKOS. One side of the Rectangular Table passes through G and the RGOW points are aligned.

RW cuts HK in Z.

By homothety of center H and of ratio which brings the line EU on the line RW, we deduce that

HZ = "jHK so that OZ is the radius of the Circular Table.

From G as center let us draw an arc of a circle radius EG, ie the length of the side of the Grail.

It cuts SV in Z and TU in S.

ZS is the side of one of the equilateral triangles inscribed in the square. We find the starting construction of the transmitter square - lesson of the <sup>st</sup> level -.

It is indeed these equilateral triangles inscribed in a square which made it possible to draw the figures generating the eifs at the EFF level. Care must be taken not to confuse the square Table with the square of the undifferentiated spectrum.

The SKUL diamond will serve as a support for the 4th Table. One of its diagonals is that of the Grail, the other diagonal is that of the Square Table.

What is said about him?

"The fourth Table covers them - The 3 Tables - and its Number is 6".

It is perhaps not the surface which is 6 although one can think of it because the diagonals of this rhombus are in the ratio 3 to 1. Taking 2 for the smallest, the area is  $2 \times 3 = 6$ .

But there is better: 6 will be considered as the number of sides. The fourth Table is therefore a hexagon but not regular.

SK cuts ZZ in Qi. By symmetry we obtain the points Q2, Q3, CU '■ QbKQi^hLCU is the hexagon sought.

IDALAB®

We find the external form containing the double labyrinth and the whole constituting the form named

IDALAB which is reproduced on each page of these booklets.

To return to the Dit des Compagnons, it must be

The Grail and the 4 Tables are not materially part of the Cheops pyramid.

They are perhaps only an invisible framework recalling the orientation of the monument which imposes its edges in the cardinal planes.

The monument will have its general lines following the NS, the EW and the vertical.

The construction that we have just exposed makes it possible to find the pyramid of Cheops. We will therefore use again the Golden Number ( $\phi$ ) but it is not in general a number which leads to balanced constructions.

If you want good proportions, you have to use the Radiant number  $\sqrt{5}$ .

Let square ABCD be the base of the Cheops pyramid. The drawdown of M on the diagonal AC of the

vertex of the pyramid with edge equal to  $\frac{1}{2} AC$  - We have seen that it was reasonable to take this ratio - is obtained by the intersection of the diagonal AC with the diagonal DG of the rectangle CDHG.

The folding of the vertex S around AB as a hinge is done in N.

The circle with center A and radius AM intersects EF at N'. AF and DG intersect perpendicularly at Q

AG intersects EF in I. From I as center, let us draw the circle circumscribed to the right-angled triangle AQG. It intersects EF in N because if the side of the square ABCD is equal to 2

$$AG = \sqrt{5} \text{ and } IA = IG = IQ = IN' =$$

$$EI = \frac{1}{2} \text{ therefore } EN' = IN' + EI = \frac{1}{2} \sqrt{5} = IN$$

This does not mean that the Egyptians took  $\phi$  in all their ratios and proportions contrary to what Fournier des Corats had found

## *Conclusion*

The Radiant number was not used in the drawing of the 3 + 1 Tables and the Grail. But if we put on the 3 tables, covered by the fourth, hexagonal, and the whole covered by the Grail or placed on the Grail, a form associated with the Radiant number, then in certain cases we link to the Idathema, to the Global everything a domain of ET. Moreover one detects the fields Z, ZD and the P-Fields - it has already been announced that those will not be approached in the course of 2<sup>nd</sup> level; we can refer to the work of Jacques RAVATIN and Anne-Marie BRANCA "Forms and Coherence" Editions: Le Cosmogone.

“Love is all the more ardent  
that  
knowledge is  
more  
perfect. »

■  
Leonardo DeVinci

Leonardo da Vinci: born April 15, 1452 near Florence, famous painter of the Florentine school, who was also a sculptor, architect, engineer, mathematician, writer and musician. Natural son of a notary and a peasant, he was nevertheless raised in the paternal family. His father brought him into Verrocchio's studio in 1469, where he became friends with Perugino and especially with Botticelli. Many of his works have been lost. He was under the orders of César Borgia, a military engineer.

He made the portrait of Mona Lisa called La Joconde around 1503-1506.

He painted the Last Supper for the Dominican convent of Sainte-Marie-des-Grâces (1496-1498).

He was, as P. Valéry said, “who could look at the same spectacle or the same object, sometimes as a painter would have looked at it and sometimes as a naturalist, sometimes like a physicist and other times like a poet. »

Let us mention his “Treatise on painting”, illustrated with drawings, in which he studied the theoretical principles of this art, and which will be admired by Nicolas Poussin.

He had invented a lute.

Leonardo da Vinci died on May 2, 1519 at Clos-lucé (near Amboise) in the arms of his pupil, Francisco Melzi.

Exercise :

Lay a flashlight on its side so that the axis of the light beam is approximately parallel to the plane of the table.

We manage so that this axis coincides as best as possible with a straight line drawn beforehand without taking into account the cardinal directions.

A sharpened pencil, placed on the table, is oriented in the luminous flux.

- 1) Check that the eifs are detected on the perpendicular to the axis of the luminous flux and that their color depends on the angle of the pencil with this axis.
- 2) Verify that this is the aura spectrum.
- 3) The perpendicular with the axis of the luminous flux constitutes the  $N_F$ ,  $S_F$ .

The axis of the luminous flux constitutes  $I'O_F$ ,  $I'E_F$  •

- 4) Check that the
  - a) pencil with point towards the lamp emits the  $V_E$  detected at  $N_F$ ,  $S_F$ .
  - b) the pencil with point opposite the lamp gives  $V'_M$ -

Note :

Care must be taken not to rotate the pencil  $n$  times  $360^\circ$  because this generates special states, other eifs which may not be at the EFF level.

## I. *Primer - Progenitor*

This presentation does not at all correspond to what we are accustomed to encountering in the rational domain where the search for details does not entail any loss of information.

It would seem that from the new point of view that we are developing, the search for details is only the effects of catching up with leaks, these being erased according to the type of thought.

Let us give ourselves a curve (C) in a plane P. The examination of a phenomenon, of an event, will correspond to the setting up:

- of a plane curve
- of two points M and N on this curve
- movements of M to the left and of N to the right.

We talked about details. Looking and going into detail will amount to moving M left and N right.

- But we go further in the sense that giving oneself MN and (C) also means setting up  $\{M, N\}$   
 $I(C) = E$  where E is a domain, imperfectly delimited, but nevertheless closed; that's about all we know about him; his frontier is on the run.  
M and N are in E

- Immediately, we see that in this partial model of thought - because it is indeed a model - the plane P is not quite a plane of Euclidean geometry. The equimsey between the couple  $\{M, N\}$  and the curve (C) gives it other characters. Thus, as there is leakage from the edge of the domain, speaking of distance in neighborhoods of this leakage will not make it possible to apply measures in these neighborhoods.
- The progressive distancing of M and N will lead to a deformation of (C).

(C) disappears locally between M and N. The “hole” that forms in (C) itself has leaks so it has no ends on (C).

- The obs wants to enrich its model, its knowledge for a more in-depth study; so he wants to impose that he always has a curve such that (C). Its intention will set up a new curve (C').

In E we can place other events, other curves bearing pairs of points. E will always be an equimsey between its pairs of points carried by these curves.

But E is not clearly defined; there is leakage on the border so the equimseys indicated above, will give domains that we can confuse with E "up to leakage".

We will therefore confuse the domains except for the leak.

Thus we can ensure that any pair of points of E and any curve passing through these points are in equimsey and that the equimsey is E.

Couples of points can be found in the flight from the frontier of E. What will be said of them? They will no longer be well located, nor will the curve passing through them. So we can no longer speak of points and portions of curves, everything is on the run. We will therefore have the leak in the leak.

### Conclusion :

We come back to the concept of examination, of becoming aware of a phenomenon, of a story. This is expressed by a displacement on a curve (C).

So :

(C) and {M,N} are given this models  
the organization  
gradually moving away from each of

(C) is as in E, but very little outside of E;

The "outside" of E is not known.

**Definitions:**

(C) is an OPEN FORM.

(C) is said PROGENER of  $\{M,N\}$ .

$\{M,N\}$  is said to be PRIMER of (C).

In these same definitions  $\{M,N\}$  and (C) are not separable.

M changes to  $M'$  then to  $M''$

N changes to  $N'$  then to  $N''$ ; placing  $M''N''$  on a curve (C') makes  $\{M'',N''\} \cap (C) = E'$ .

$E'$  is a runaway boundary domain, in plane P.

$E, E'$  enters into the elaboration of what we call a FOLIAGE.

So we act in a plan, plan P.

We see that the obs develops two dimensions.

The set of domains  $\{E, E', E'', E''', \dots\}$  will constitute a neighborhood of the obs in 3 dimensions.

The deformation of (C) then the leaks that arise between  $M'$  and  $N'$  are due to the impossibility of the obs not being able to encompass (C) in its entirety.

The obs is aware of (C) but cannot represent (C) as a whole. This is what characterizes the open forms

Let's see the event  $\{\{R, S\}, (D)\}$  in E.

We have seen  $\{M'', N''\} \cap (C) = E'$  up to the escape

$$\text{or } MN \rightarrow M''N' \\ (C) \wedge (C)$$

and  $(D) \rightarrow (D')$  curve such that if

$$\{R, S\} \rightarrow \{R', S'\} \rightarrow \{R'', S''\}$$

then  $\{R'', S''\} I (C') = E'$

Thus  $\{\{R, S\}, (D)\}$  is not a primordial event, dominating since  $\{M, N\} I (C) = E$  and  $\{R, S\} I (C) = E$

### Consequences :

We have just put in place a kind of reverse of what surrounds us. It is a necessity of the cerebral process which is expressed formalized by the model. She's not the only one.

The foliation, that is to say the set of  $E, E', E''...$  will constitute a neighborhood of the obs, a neighborhood in 3 dimensions.

This is reminiscent of how a story unfolds when you read a book page after page. Going from one page to the next is the equivalent of catching up with the curve  $(C)$  by the curve  $(C')$ , then  $(C'')$ ... The story begins in  $E$ .

If we only had  $E$ , it would be dull, with no follow-up.

With  $E, E', E''...$  the leafing, everything happens as if we had placed theater sets in which no play is performed. There are only heaps of stories.

The domains  $E, E', E''...$  are filled with intentions.

## HE The concept of time

The transition from (C) to (C') establishes time.

Time is going to be the attempt to rebuild the curve.

The displacements of M and N correspond to intentions.

Thus the foliage creates time and imposes a relation of order.

Setting up the foliation seems to take time, since there is a before E and an after E', a before E' and an after E'.

This is where you have to think differently and go further in the construction of the model.

To obtain the equivalences E, E', E'',... it is necessary to start from a curve. It is the same for all equimseys. It is closed and will serve as a support for attempts to reconstruct the curves (C), (C'), (C''), ... An attempt will consist of traversing the closed curve. Each attempt will be a course of this curve by the obs.

### Note :

It should be noted that the obs considered here only exists through these leafing actions.

The realizations of foliations express the obs as he realizes these foliations. It is not separable from them. So we cannot speak of a time before the time that will generate them. It is not at all Dunne's view of time which is a recursive construction.

We are gradually entering a domain where we cannot define an entity. It is often necessary to associate it with another and to combine them by a process which is not in the usual C. de C..

### Foliage and swarm :

A swarm develops in the ordered set of layers that constitute the foliation. The number of domains in the swarm is not known.

This swarm moves like a cursor over the ordered set.

Thus the intention of the obs discovers 3 faces:

- (i) M and N move.

- (ii) (C) is rebuilt following (C').
- (iii) The swarm and its movement.

The swarm constitutes what for the obs is a story or a set of stories that can unfold simultaneously.

The movement of the swarm is based on the continuity of time.

The form, the event are put in place by all the sheets.

Irregularities are likely to form in the leafing: leaves can stick together, which affects the understanding of the story(s).

It can also happen that a swarm leaves its foliation to be replaced by a swarm which belongs to the foliation of another human being - the other human being constitutes what is called a DENSIFICATION POINT of the obs -. So the obs has stories that are not his. It is one of the faces of what some call Reincarnation. It has many faces but it is not the fact of having already lived.

Swarms between that of the obs and that of one of its densification points can enter into transfer. This is also another face of reincarnation.

Suppose the curve (C), in the plane P, closed; take it as a circle.

If the plane P has the properties:

- (i)  $\{M, N\}$  primer of (C) (Am for primer).
- (ii) (C) progenitor of  $\{M, N\}$  (Gen for parent).

Then  $\{M, N\} \cap (C)$  is the whole plane P, and this because (C) is closed.

Suppose three points  $M_1, M_2, M_3$  on (C) such that:

- (i)  $\{M_1, M_2, M_3\} = \text{Am}(C)$ .
- (ii)  $(C) = \text{Gen}\{M_1, M_2, M_3\}$

Then  $\{M_1, M_2, M_3\} \cap (C)$  is the whole plane P and this because (C) is closed.

## *1. The halo*

### 1 ) Coherence

The human being, when he thinks, relates to Coherence.

The meaning behind this word is very subtle. It emerges in the form of an echo in everyday language where we speak of the coherence of each scientific field such as physics, chemistry - exact sciences - , then biology, medicine, meteorology, etc.

The coherences seem multiple in our modern world.

But we are not talking about these coherences but about Coherence.

Coherence is like a cement in which the observer plunges his trowel: a parallelepipedal trowel will allow him to make blocks of this shape and will make a house with these shapes. A trowel of another shape, for example cylindrical, will allow him to make cylinders and by assembling them to make a house, other than the previous one.

From the same consistency - cement - different worlds are elaborated - houses, the first will guarantee from rain, wind, etc. the second is made for arid and windless regions -.

Coherence is therefore not defined, but it is expressed in its consequences [1].

We have seen in what precedes that a form can be thought of abstractly or placed in a certain vicinity. In the latter case, when looking at a painting, the expressions foreground and background are often used.

The observer then takes on all its importance. It takes into account the shape and a certain surrounding of the shape - which, from the usual point of view - would be placed in a subjective way.

Whether the form is seen as an abstraction or the form with its surroundings, this does not interfere with the fundamental assumption of the form emerging or immersing itself in the space-time (ET) structure.

The form seen in the foreground can be detached from the background or, on the contrary, seen with the background; in the latter case it will be said that it is considered to be "flattened" on the bottom.

Stéphane Luspaco [2] points out in his works, the "Gestalt-Theory" thanks to which this basic concept was introduced.

This form placed on the background takes on a new character that we call the "AUREOLAIRE" of the form [1], [3], [4].

Let's do the same procedure on the ET, that is to say by transport of structure let's apply the concept ET on the Global which is the existence without landmarks.

It appears the Halo of the ET which is what the Ancients called the ÆTHER (Æ).

## 2 ) Remark

The ether of the Moderns is not Æ of the Ancients. The Moderns looked for the æther which they called ether. The Michelson-Morley turn-of-the-century experiment and other experiments demonstrated that ether does not exist.

It was initially, for physicists - therefore for the Moderns - a fluid body, whose existence spread in the Middle Ages, this by what was left of the knowledge of the Ancients. Physicists have taken up the ether to explain the propagation of light. The Frenchman Fresnel, taking up the hypothesis of Huyghens, demonstrated that light is a vibratory (or undulatory) phenomenon which is propagated by waves; physicists abandoned Newton's hypothesis of an emission of luminous corpuscles.

But if Newton's corpuscles can do without a support, it is not the same for Fresnel waves which need a continuous medium in order to be able to propagate.

But light propagates in a vacuum, which led physicists to assume that all space is filled with a continuous medium: ether.

The ether, not slowing down the movement of the stars, had to be infinitely fluid, but as it transmits luminous transverse vibrations - which Fresnel's contemporaries could only imagine mechanical - it had to be perfectly elastic - without deformation, like a bar of infinitely rigid steel - which is contradictory.

Maxwell demonstrated the electromagnetic nature of light, which meant that in the 19<sup>th</sup> century the (contradictory) mechanical properties of ether had to be abandoned. It was left with only electrical properties.

Then the role of the ether diminishes to no longer be a simple body of reference linked to absolute coordinates of space. But ether is still troublesome; indeed if there existed a medium such as the ether, fixed with respect to absolute axes, the propagation of the light emitted by a moving body, such as the Earth, taking place in this fixed ether in all directions, would not should not have the same apparent speed on Earth in all directions.

However, the speed of light (300,000 km/s) compared to the speed of the Earth in its orbit (10 km/s) does not vary as shown by the experiments cited at the beginning: the speed of light in a vacuum is the same whatever the directions.

Some wanted to explain this failure by the entrainment of the ether but finally the physicists abandoned the hypothesis of its existence.

Einstein, establishing his theory of relativity, showed that there cannot exist systems of privileged axes - absolute axes to which the ether would be linked -.

The limit speed of light is the expression of a decalare, an expression in a thought where the flight of landmarks does not exist. We find by experience, which is placed in the usual field of coherence, that the speed of a mobile cannot increase to infinity; a barrier is put in place, which is measured, and which expresses a decalar in the usual form.

### 3 ) The halo (continued)

The halo is most often found in poetry in metaphors.

The poet, in order to pass on the sensation to those who delight in his writings, uses a device of the kind: A is to B, what C is to D. Most often the sensation is forgotten.

From these 4 written terms (A, B; C, D), there springs a fifth which is still called AUREOLAIRE.

On the other hand, in mathematics, the proportion  $\frac{AC}{g} = p$  does not involve any halo.

Let's see the 4 terms:

(Form, Content; AND, Overall); this has as halo the  $\mathcal{A}$  and we will state:

The Form is basically what the ET is to the Global, has as aureolar the  $\mathcal{A}$ .

When we only have 2 terms, which we saw at the beginning, we go to 4 by the above process.

In conclusion, projecting A onto a background, or stating (A, Background; AND, Global) means the same thing and generates the same concept: the  $\mathcal{A}$ .

There will be other projections of a form A on a form B which will not be the equivalent of a background. According to Gilbert Simondon [5] conceptualization is to perception what syncrystallization is to crystallization, which we will write:

(Conceptualization, Perception; Syncrystallization, Crystallization) has Coherence as its halo.

Note : Syncrystallization for: crystallizes together in the same homogeneous crystal in any proportion, this forms a homogeneous crystalline mixture.

So we got Coherence as a halo. It can be obtained otherwise, as equimsey.

Let's see the concept of representation of the obs. - we saw in a previous booklet how the obs generalized the observer -.

Let's obs I representation <sup>1</sup> = Consistency

but obs I a representation := domain of coherence.

This makes it possible to associate the concept of domain with that of coherence. Consistency is a unity. It cannot be divided but this process nevertheless makes it possible to construct the domain of coherence, which cannot be approached by a partition of the coherence which we would call domain.

Coherence presents itself either as a halo or as an equimsey.

Maybe there are other possibilities?

Among the Chinese, the seasons were not presented in their natural order of succession, but according to alternations:

- the South complemented the North,
- the West complemented the East.

Then we added a center.

So we had 5 terms: N, S, E, O and the Center.

Consider it this way:

(N, S; E, O) has the Center as its halo.

Similarly the Chinese created correspondences between the 5 elements and 5 colors, 5 musical notes, 5 numbers etc. [6]

(Summer, Winter; Autumn, Spring) has the whole year as its halo.

<sup>1</sup> Reminder: A I B means A in equivalence with B.

(Red, Black; White, Blue-Green) has yellow as its halo.

(2, 1; 4, 3) has the number 5 as its halo.

the total year  
the color Hence the  
number 5 > were much more than what we usually put in a year,

a color, a number. These notions are delocalized.

These are the usual notions which are surrounded by a halo, hence the name halo.

Matches go to:

- 5 geniuses of the Orient
- 5 Sky Palace
- 5 Heavenly Signs
- 5 Virtues
- 5 Flavors
- 5 Pets
- 5 Odors etc.

This correspondence between 4 elements which gives a fifth is not done just anyhow.

There is a Necessity. Necessity is fundamental as we have pointed out.

One can wonder in the provision (A, B; C, D) the reason for this provision.

The people of that time did not think like us; concepts were natural to them, and arrangements between concepts were also made naturally, like metaphor in poetry; it is a certain arrangement in 4 terms which conveys a sensation; another arrangement of these same terms is unthinkable.

## *II. Remarks on the number 7T[ 1], [3], [4]*

J. \_ Ravatin in the courses relating to the eifs that he gave in Paris from 1975 to 1993, pointed out the choice according to civilizations and times of the approximate value given to certain numbers, in particular that of TC. The history attached to TC is now considered a curiosity while on this example we can feel the notion of more or less localized. The importance of the TC number is such that

we must take up a brief history of it. The Babylonians and the Hebrews admitted that the length of the circumference is three times the length of its diameter; the Egyptians identified  $\pi$  with  $A/T\hat{O}$  (which allowed the value 3.1123). Archimedes asserted that  $\pi$  is between  $3 + \frac{1}{60}$  and  $3 + \frac{1}{40}$

i.e. between the two decimal numbers 3.140845 and 3.142857. The Chinese and the Japanese had also found decimal values; in the 12<sup>th</sup> of our era the Hindu scholar Arya-Bhata had

found 3.1416. In the 16<sup>th</sup> century the Dutchman Pierre Miétus gave the value  $\frac{355}{113}$  which provides five exact decimals. The Frenchman François Viète around 1593 calculated  $\pi$  with 10 exact decimal places; in 1610 Ludolph van Ceulen succeeded in obtaining 127 decimal places. In 1873 the Englishman William Shank obtained 707 decimals. In 1882, Ferdinand Lindemann demonstrated that  $\pi$  is a transcendent number. Thus is found definitively proven the impossibility of squaring the circle, that is to say side of a square whose area would be equal to that of a given circle.

Marcel Boll, quoting Lancelot Hoghen, adds: "An American state has tried to restore  $\pi$  to its biblical value (II<sup>e</sup> book of Chronicles, IV, 2).

Doubtless the "reformers" have never seen a saucepan, nor a measuring tape (it suffices to measure successively the perimeter and the diameter of the bottom of the saucepan, to realize that  $\pi$  is greater than 3); but these same people mechanically repeat the famous phrase of the Psalms "They have eyes and will not see", without suspecting in the least that it applies to them; a fine example of this obscurantism, the deplorable effects of which can be seen everywhere".

It is quite surprising to see that the Babylonians, the Hebrews had taken the value 3 for  $\pi$ ; the error is hardly conceivable. And yet, that's what they took! Let's see it another way.

22

The values 3 -  $\pi$  - 3.1 - etc. are too gross to be considered errors. For our C. de C. these are errors, but in a way voluntary errors. To take 3 for  $\pi$  is to consider an already delocalized circle. Thus ( $\pi$ , 3; delocalized, localized circle) has an aureolar which is a circle a little less localized than the circle thought of in geometry where the localization is complete. They therefore thought of the halo, that is to say a depth was felt and had to be expressed. The circle drawn on the monument had to be placed where that depth reflected on whoever was looking not at the circle but at the monument on which the circle was drawn.

This turn of mind led to paths other than the path used now. Moreover, even if the circle was drawn according to our geometric formulation, the circle was not thought of as a circle alone but on a building, in a place, it could be less localized with the surroundings. This is what we have already indicated by saying that two triangles in a plane, in certain positions, are perhaps no longer quite two triangles, one can partially delocalize the other; looking at both at the same time is not the same as looking at one then the other; in Cartesian thought we confuse two approaches, because we forget the approach, we do not reinvest it. It is necessary to reinvest it if one wants to be operative: to be operative is almost to ask permission to start again a second time an act which, for its part, had all its value, because it occurred at a given moment. This act was not separable from the moment; to be operative is to take it up alone and place it at another time, even if we know that it is not exactly the same act; it is here that we understand what humility is: it is the expression of the state of an attitude.

“They have eyes and will not see”; Lancelot Hoghen, in quoting this extract from the Psalms, forgets that it is for him like a "return shock". You have to feel the delocalization to measure how much the Babylonians and the Hebrews, taking 3 for 71, thought of the circle in a totally different way from what it is in rationalism. To consider a delocalized circle therefore amounts to thinking much more than the circle.

EUREK' ALL

“We regard the soul as  
the most important  
thing  
and  
the most mysterious of all »

said an Eskimo Iglulik to the explorer Rasmunssen

? This took place at the beginning of the 20th century and went unnoticed. Rasmunssen was dismissed, his work forgotten, and people set out to discover "savages" who were more docile to the theories of the rationalizers. Jean SERVIER, in his work "The Man and the invisible", Edit. Robert Laffont, Paris (1964) adds "No one thought for a moment that this great Danish scholar owed to his Eskimo maternal ancestors to be able to skip the long stages that all seekers go through when they go to the discovery of deep faith. of a people".

Exercise :

We wrap a copper wire on a broomstick for example, in the positive direction (also called trigonometric) - that is to say in the opposite direction to that of the corkscrew -, Five to six turns are enough.

At each end we pull the wire straight for about twenty-five centimeters and so that the assembly placed on a table has its 2 strands of wire on the table over their entire length.

We put a pointed pencil on the opposite side to the point in the center of a circle drawn on a sheet of white paper (without grid) - the angle at the point of the pencil being approximately  $30^\circ$  -.

The axis NF, SF coincides with the axis of the solenoid made above.

We will build 2 cylindrical pendulums LH and LY - in square Hebrew -.

- 1) Check that such a pencil placed as above in the center of a circle emits the aura on the circle.
- 2) Find the polarities
- 3) Check that on the axis of the circle we detect LYLH

Note :

This experiment is one of those which led J. de la Foÿe to think that at the EFF level, the eifs of the undifferentiated spectrum were made up of the eifs of the differentiated spectrum, ie A is composed of AM and AE.

It is necessary to pay attention that we are not in the rational field and that an analogy can be essential in the research radiesthesic.

$$\vec{A}_E$$

About this experience and others that seem to lead to

----- same conclusion, Jean de la Foÿe was imbued with the model of p  
electromagnetic field where an electromagnetic wave is sub-

$$\vec{M}$$

stretched by 2 vectors E (electric) and M (magnetic).

If we start from this model and want to impose it, we find it. This must not be forgotten. It is excesses of this kind that lead waveformists and certain geobiologists to erroneous terminologies and conclusions through models and abusive uses of terms taken out of context such as energy, force; they see flaws everywhere; the currents

water does not systematically bring a  $V'E$  to the surface, the  $V'E$  due to HT lines depends on the orientation of the line; they forget the states.

In houses they constantly invoke the “memory of the walls”. But we must try to understand what "memory of the walls" means.

Shapes, objects can change state when states are created in their vicinity. It is this change of state which is then captured.

But there is still something else: space has the property of being impregnated by shadows: shadows due to the presence of a form on a light path. Shapes can even keep shadows stable. In the shadows remain present unfolding events. The shadow may even have disappeared and the event is then existing in space. The shadow left its mark.

Goethe was interested in shadows and he pointed out colored shadows [7].

The shadow gives depth to the space. The shadow is a face of the halo of a form.

- 4) Check that on the NF-SF axis in the plane of the leaf, LY and LH are detected (the 2 pendulums must respond) but not LYLH.
- 5) If we draw the circle of radius  $y$ ,  $R$  being the radius of the previous circle, we find the tree trunk.
- 6) Install the solenoid.
  - a) Check that at the ends of the 2 wires we detect LH and that in the axis of the solenoid we detect LY and this for most orientations of the rod.
  - b) At any orientation of the pencil, it is verified that the eif previously detected at  $V^+M$  has disappeared.
  - c) If we set the pencil to  $V^+M$  OR  $V^+E$  we detect LY on the axis of the solenoid but no LH at the output of the copper wires. The eif  $V^+M$  OR  $V^+E$  IS DETECTED on the axis.
  - d) If we set the pencil to  $V'M$  OR  $V'E$  we detect LH at the output of the copper wires but no LY on the axis of the solenoid.

The eif  $V'M$  OR  $V'E$  IS DETECTED at the output of the copper wires.

**LH**

**LY**

## Chapter XI

### *I. Supplement to Chapter VIII of Fascicle 15*

We had drawn the arc of a circle of radius AM which intersects OF at N". We can see that N and N' are very close; indeed :

$$AM = AC = \frac{2}{4y/2}$$

$$EN' = \sqrt{AN'^2 - AE^2} = \sqrt{2.47959^2 - 1^2} = 1.5986$$

$EN - EN' = 1.6 - 1.5986 = 0.0014$  which is negligible in the domain of eifs.

### *II. Right triangles of side lengths a, b, c such that $a^n + b^n = c^n$*

Triangles in general respond to  $|K Sh Ph\rangle$  but the right triangle with sides a, b, c such that

$$a = 3$$

$$b = 4 \text{ • does not respond to } |K Sh Ph\rangle.$$

$$c = 5.$$

Jean de la Foÿe had found this result.

But it is the same for right triangles with  $n = 2$  and a, b, c integers such that  $a^2 + b^2 = c^2$ .

A triangle which does not correspond to the state  $|K Sh Ph\rangle$  is the so-called Cordonnier triangle and whose sides have the value 1,  $\sqrt{A/V[']}$  it is constructed by giving the angles  $40^\circ$ ,  $60^\circ$ ,  $80^\circ$  which are only

approximate values but are quite sufficient in this field of eifs.

Draw the incircle of square ABCD. Let us draw by Q the parallel to the sides AB and CD of the square; it intersects the inscribed circle at P and EF at N.

ON is equal to a height of the triangle DQF.

$$GR ON 3 ON$$

$$DF + GR NC + ON 5 OP$$

If, in the right triangle ONP one side is equal to 3 and the hypotenuse equal to 5, the other side of the right angle is equal to 4.

Remarques :

- 1) These results come from the fact that we took the edge of the pyramid equal to the diagonal of the base square. It seems that in this way we enter fully into the tradition.
- 2) By manipulating these lines in this way, we realize that we find fractions which are none other than those of the notes of the natural scale of Zarlin (1517-1590), Italian composer and theoretician, pupil of Willaert. Most of his works are lost, but he remains, from the point of view

theoretical, an eminent musician. Nowadays, we continue to take into consideration its scale based on the perfect chord and formed of fractional intervals [8].

It seems that the Zarlin (or Zarlino) scale was chosen for reasons related to polyphonic music.

By manipulating the lines, we realize that we find fractions which are those of the notes of the Zarlin scale. Of course these fractions corresponding to lengths are inverse to those of frequencies. Some notes seem a bit "far-fetched", but we're not looking for balance here, just a series of lines.

We can build Tables in Do, Mi, Fa, Sol, La but the Ré (^) and the Si (yy) are absent as if they were according to the geometry of the bastard notes.

The Pythagorean conceptions made no fundamental difference between plastic arts, music and the description of the cosmos and they are governed by numbers.

We can think that we go in this direction by finding these relations between Tables and the notes of the scale.

One can suppose that an architect, like the composer, must operate a selection of proportions which leads to harmony. It must be recognized that certain architectural achievements are absurd - one verifies the harmfulness of them by the eifs and the states which emanate from them.

Moreover, modern architectural achievements are placed in the middle of old constructions and a disharmony immediately presents itself to the view but also for those who live in the old as well as in the modern.

Note : If we make the 3 Tables and we build the homothetics which will be Mil, Soli for example, they are not in transfer with the respective notes, when these are played by an instrument which gives the pure note or the note with its harmonics, even if the Tables are suitably oriented.

# MUSICAL TABLES

On the other hand, if we draw the 4th <sup>Table</sup> - hexagonal - and the Grail, then the other Tables Mil, Soli, D02 are in transfer with the respective notes.

When a musical piece is played in which these notes occur, what is emitted by the polyphony is emitted by this set of Tables - there is not one Table per note, only a few notes are represented like Mil, Soli, D02 , S0I2, etc.

- 3) Regarding the dolmen, eight-tenths of the dolmenic axis correspond to three-fifths of the semi-axis of the Grail Table.

On the other hand, from the historical point of view, it is likely that the designing monks drew part of their data from the Bible, and also from the direct knowledge they had of the world in which they were; this world was perhaps not quite like ours and could perhaps be better penetrated. Moreover, the rational coherence field may have slightly erased certain structures.

The monks did not have to draw from constructions like the pyramids. But they were also linked to the Great Tradition, the one that has always been talked about a lot and which was really discovered by Louis Boutard. This researcher, who embraced things before understanding them, from his knowledge of twenty-eight languages managed to show - he made many devices which confirmed his hypotheses, however very bold - that the Ancients had a knowledge immense and different from current scientific knowledge [1], [3], [4].

He used the Dorian Gnosis - let this not put some people off, a lot of nonsense has been written as appreciations on Gnosis, but with a genius like L. Boutard everything becomes clear and there is no more antagonism between gnosis and Catholicism -.

Note :

Be that as it may, it is interesting to find out how and to what extent the builders of the past used the Tables even if this does not reveal either their origin or that of the “Said”.

Let's see the temples of Jerusalem, Solomon and Zerubbabel.

## Temple of Solomon

They adopt the Carré and the Carré Long Argenté. The variants manifested themselves in the vestibule (Ulam), outside the Grail, but attached to it.

The odds are 1 to 1 or 1 to 2.

## Tabernacle of Moses

The humans of the time of the menhirs, or let's say the times of the menhirs because on the planet we had to make them at various times, are not attached to relationships. They felt the environment much better and it is not sure that they were looking for a point but rather reasoned by domain or volume in space and built in this domain.

They certainly worked much more with what we mentioned above: the “depth of space” or the faces of halos of shapes, of places.

In these aureolar faces they placed their feelings, their fears, their hopes, their desires; they could thus dialogue with others themselves.

Thus the menhir considered under the modern point of view teaches little even for waveformists and others.

One can discuss the reason for its location on the bisector of the angle of two lines of esav (see booklet 14). It has been pointed out (Paper 14) that menhirs can be used with other shapes to create certain fields (Z and ZD).

**CHARTRES Schéma idéal du plan au sol**

The dolmen taught us the  $\frac{8}{10}$  of the axis of the Dolmenic Table which correspond to  $\frac{3}{5}$  of the semi-axis of the Grail Table. It is the only measure of this provenance that can be found in the Tradition based on a religious support going from the time when Moses lived, to the builders of cathedrals of the Middle Ages.

With regard to the latter, it is likely that the designer monks drew part of their data from the Bible and not from the pyramids and other monuments whose precise dimensions must have been rather poorly known. On the other hand, it seems that this period had

also knowledge of geometric data of Pythagoreanism bringing a harmony perhaps imbued with gnosis and Kabbalah.

You should know that gnosis has gone very far in the field of knowledge; unfortunately it has been considered as being in antagonism with Christianity. It may have been, but there have always been people who took pleasure in creating antagonisms to use them for other purposes. Moreover, gnosis has been little understood by the moderns, it's a bit like the æther; one can even say that it is now absolutely misunderstood and that only the works of Louis Boutard and perhaps Montfaucon before him have given any idea of the intellectual level reached by gnosis. There were multiple gnosés but in this multiplicity the spirit of the great gnosis was diluted.

Be that as it may, it is interesting to find out how and to what extent the builders of the past used the Tables even if this does not reveal either their origin or that of the “Said”.

It has already been pointed out in the previous booklets of this training that the Ancients thought differently from us and that it was normal that they easily obtained information from their intuitions according to their intentions and needs. In thought they were much closer to their intuitions. These were manifested in the context of their time.

We see that variants between the Temple of Solomon, the Tabernacle of Moses, the Temple of Ezekiel, appear in the vestibule (Ulam), outside the Grail, but are attached to it.

The vestibule of the Temple of Solomon has width 1 and length 2, that of Ezekiel is 3 wide and 5 long - rectangle called Long Golden Square (already used in the Ark of the Covenant which in particular is the generator of the Node of life.

### Temple of Ezekiel

You have to dive back into the Bible, which is available to everyone - that's the advantage of this book, but it can't be read routinely as some religious groups commonly do.

Descriptions are still fairly accurate. But let us return to the religious; they have made usable constructions which perhaps would have worked less well because there is the question of the moment.

Then they gave flexibility and resulted in the flowering of Romanesque, then Gothic cathedrals. There are still sketches of these constructions in the neo-classical "Jesuit" style and in the Gothic "Napoleon III". Appearance and technique delude this, but the intangible skeleton of the Tables is no longer there to create the atmosphere of serenity, balance, well-being that

remains the lot of the great era with its global knowledge of the links between the monument and the telluric currents, constellations.

Cathedrals of the Middle Ages rest on a crossing of lines of esav - This may be true for all of them but we have not verified it -, Chartres cathedral seems to have an abnormal orientation; the probable cause must be sought in a deviation of the lines of esav from the cardinal planes.

The diagrams reproduced here clearly illustrate the use of the Tables insofar as one can trust the reduced plans which made it possible to construct the design and to dominate the real irregularities of the buildings.

The people of the Middle Ages possessed enough of their art to allow themselves fantasies in the execution. They knew how to comply with secondary imperatives which did not alter the essential properties of the plan, like a plant which never reaches geometrical perfection and which is never the serial copy of one of its sisters. - moreover, identical copies could cause fractures in the rational C. of C.; yet this is what some are beginning to put in place with cloning -.

Moreover, the companions, workers who worked on the cathedrals were immersed in the intention of creating a building - at that time, their thinking allowed them to do this - and they made "variations on a theme" which were in harmony with the project.

Why was such an ordinance dropped? At least if we judge by the works subsequent to the radiant Gothic, the flamboyant Gothic, in fact, has already lost the great secret.

The bell tower of Jean de Beauce, in Chartres, may be a masterpiece of static equilibrium, but it no longer emits the adequate spectrum of eifs - at the EFF level -, and there is no that one! We have already seen the fields of Taofel and there is still a lot to see like VC, FV, the Ifs (4 in number), the Avæcum, its components, the Pavs, the Z and ZD fields, the P-fields, Arkhams and Mahkras and that may not be all; you have to stay very open, always listening

The Templars, it is said, carried away their secrets following the banning of their order by Philip the Fair, who Philip the Fair intervened against them at the request of Pope Clement V, and who this pope was placed under certain conditions by organizations that long ago made a point of setting up the system we know.

The Templars probably left geometric rules to operative masons.

Remember that previously the rules were polluted by a mathematical heritage relating to the Golden number which we wanted to make the rule of all harmony. This number, as we know, had its great vogue among Renaissance artists.

In fact, there is much to think that the Templars who were not already the initiators left only processes whose roots formerly vivified by the Benedictine and Cistercian monks were dead. And as happens with all processes detached from their origins, only traces will remain, reduced to the helping hand of the trade, this for the operatives, and to an intellectual geometric symbolism for the speculative ones. But let's not forget that the Templars had understood the concepts of relocation, Global and others - what was left of it was put in the form of an occult knowledge which lost all the "substance marrow" of it - and so they were less attached to the search for eifs but more to those of C. de T. and their escape, then everything else, down to the ZD fields and the P-Fields as well as other existences like the global or the idatheme.

Should we go from decadence to decadence?

The architect, nowadays, in an anarchy that ranges from the concrete rabbit hutches - real homes of V' E - to the skeleton dressed in guts of the Center Beaubourg, images of a decomposed society, without ideals, without spiritual reinforcement and without hope , ripe for new barbaric periods, is unfortunately oblivious and serene.

It would be a shame if we couldn't once again breathe life into a form that integrates into the rhythms of life. It's fine to go to war in the name of ecology. What good is it if artificial environments run counter to nature.

To regain common sense, you have to think differently - which is developed in Coherence Field Theory [1] and work on Forms from this new form of thought that we present little by little in this course. -.

Ruler and compass will be useful to us but it is necessary to go much further, geometry and algebra are necessary and the mastery of intuition is the most fundamental exercise.

<sup>2</sup> according to Montaigne's expression.

Exercise : We start with cardboard squares and we draw on them in India ink two perpendicular axes, parallel to the sides, intersecting at the center of symmetry. This center will be punched out

O

has

b

O

vs

% Magnetic (198.°5)

1/3 Electric (108.5)

3/10 Ecuador (Shin)

e

? -----f

3/5 Knot of Life

0,  $\bar{6}$ ,  $\bar{3}$ ,  $\bar{2}$ , 1

The underside of each card  
is like this

This done, on the right side of each square of bristol, we draw parallels to the sides, distant from the center by a determined fraction of the half-side.

Check that :

We detect respectively above the center with specialized pendulums

- 1) Fraction  $\frac{3}{4}$ : Emission of the Node of Life
- 2) Fraction  $\frac{1}{2}$ : Emission in M of  $198^\circ.5$  (on the transmitter disc - Be careful that with the square emitter it would not be the same angular values.
- 3) Fraction  $\frac{1}{4}$ : Emission at E of  $108^\circ.5$  (on the transmitter disk)
- 4) Fraction  $\frac{3}{8}$ : Emission of the
- 5) We put in the center of one or the other square of bristol a form emitting an eif - level EFF -, for example a  $V^+M$ .

We will take a ring of small diameter, approximately that of the hole obtained with the cookie cutter in the bristol card.

And we put the card such that its center is confused with the small copper ring.

Show that only the fraction will disperse the  $V^+M$  over a distance disproportionate to the specific "power" of the cardboard, in the room where one is operating.

- 6) Then check that after a certain time - you have to wait 5 to 10 minutes -, beyond that, as if the electric  $j$  associated with the magnetic  $1$  was the start of a carrier eif field.
- 7) If we associate  $r$  and  $v$ , check that we no longer find  $V^+M$  around the cardboard.
- 8) If we add  $7$  to the previous ones, that is  $zx\ 7$ , the  $V^+M$  - called ambient because it is detected in a volume of space in which the cardboard square is - is detected.

Note : These experiments do not provide access to C. de T.

If we placed in the center of the cardboard square a form emitting a C. de T., or the flight of the C. de T., nothing of what has just been presented in exercise would occur.

Conclusion :

We realized that many past events, forms created in the past - this can sometimes go back a few centuries and often much further - do not reveal their secrets easily and that it is necessary to use artifice to raise the sails; because it is indeed veils. It seems that the past, like what is far out in space - asteroids, meteorites, comets, and much further still - is covered with protection and cannot be approached directly.

Approaching these forms, these events therefore requires a preparatory study which differs according to each person.

The study of celestial bodies such as the photographs present them to us is very rich if we know how to approach these forms.

In addition, the following fact must be taken into account: any study from the photograph of a form, of a place, uses photography as a support; from this it emerges that the transfer between photography and form must be placed , or the photograph and the location.

. Naturally photography emits eifs, creates states in an environment even much further away - but that's not necessarily all that will be detected in the form, the place.

## *1. Back to some concepts*

A representation is placed in a field of coherence; it can even impose a field of coherence. Thus a definition that is too hasty can lead to a break even in the field of coherence by extension of a representation in this field of coherence [1].[2] [3] .

The usual field of coherence obliges each human being to plan, to extend to communicate with the other human beings, the human being "integrates", such is the expression devoted, to the society which, it, is rational . What a human being gains by blending into a society, he loses in himself; he loses his personal power. He becomes more fragile, because he is more easily identifiable in this society in which he has melted by identification. An individual, in our rational society, is perfectly identifiable. He is followed from his birth to his death and this more and more. Electronic systems will further perfect, credit cards for example, this imprisonment of the individual in the midst of others. We thus obtain an overlocalization compared to the usual localization and this individual in the mass of individuals, overlocalized will bring about breaks in the concepts of crowd, society, entities already delocalized, to relocate them and these relocalizations will themselves produce overlocations. But this process of overlocalization can lead to localization in the field of rational coherence.

It is not so much the action of merging (in rational society) that is serious, it is the spirit in which the human being is merging. He loses the possibility of becoming aware of the concept of coherence field and is no longer himself because a coherence field can be more or less in tune with a living being, especially as this field develops. At the beginning, the launching of the field can be satisfactory but afterwards, impurities appear, especially when it comes to the rational field. It then slips into the field of incoherence that all human beings, constituting society, wanting to be rational, try to have accepted as coherence.

Concepts can belong not to coherence, but to incoherence and these concepts entering a field of coherence pollute it.

In the point of view developed in this course, a human being does not exist in relation to others, we will say "is not in relation to others", the others are only because he is. However, only those who are aware of it can speak of it. But we don't have the right to think this same position for others, otherwise we fall back into the usual field of coherence.

In the rational representation, the individual is led to play the game of scientific pseudo-objectivity: that is to say, we want to align the values, compare the results. Pseudo-objectivity is in this possibility of constructing multiple scales of comparison, but this is often arbitrary. The RBBs who apply it as much as they can (it is a justification of their behavior and a necessity to be recognized as a good scientist) extend it to human relations and morality. We arrive at absurdities.

This freedom that the researcher gives himself in his construction and projection of scales of values is an illusion. He thus gives flexibility to the usual field of coherence and believes that there is an escape outside of man in a generalization of concepts. The human being is caught in a straitjacket: his usual field of coherence makes him a prisoner. The notion of freedom is brought to make him forget this straitjacket, freedom is a dilution.

This freedom (and at that moment, we no longer have to talk about it because it is implicitly understood) is in another field of coherence, this one in which the being projects itself at the same time as it puts itself inside. . This last concept belongs to another field of coherence, but then the rational field of coherence can be rethought starting from this other field; little by little the notion of coherence field becomes clearer, still without defining itself, the usual field being by construction the negation of coherence field since it considers itself as universal, wanting to explain the universe that it allows to discover, whereas with the other field the obs becomes aware that he discovers, creates because he launches and gets into it at the same time. This replaces the "Know thyself" from the Temple of Delphi; moreover thought which is continued by "And you will know the Universe and the Gods".

The being then knows that he is the alpha and the omega.

In most works dealing with non-orthodox subjects, reference is often made to the human being who is the alpha and the omega; the meaning is given: beginning and end. This is intended to be a deeper explanation than that which is usually given, because it blocks, for the reader, any search for deeper sensation. If we think of the field of coherence that we launch and in which we put ourselves, the alpha is generated by the omega in which it is; the alpha and the omega are in dynamic duality in the sense of creation and capacity.

In Eastern philosophies, reference is made to "the truth which is in itself". Translations and understandings of this phrase are generally poor and perhaps the authors, themselves, expressed in words what they felt without much concern if others

interpretations, more or less erroneous, were possible. In any case, when we look at texts dealing with these questions, we must put ourselves in the state of mind that we must adopt when reading or stating a proverb (proverbs expressing common sense popular) ; that is to say, at the same time as one assimilates the saying, the proverb, one must discover its way of understanding <sup>1</sup> . Likewise, the reading of these booklets proceeds from this principle.

The form is fundamental in the approach of the global because it emerges or immerses itself in space-time but also, it is the way. At the same time as we set up the model, the representation or representations, we must follow the spirit in its approach. You need the object (the model) and the image (the way). From the image we draw the necessary discipline of mind when we leave the usual field of coherence, discipline which in this case is implicitly understood, so as not to fall into phantasmagoria, these perhaps not belonging always in the realm of the absurd (most often they belong to it).

Rational thinking has eliminated fear of the demands of multiple gods and superstitions.

Indeed, the human being having these entities in his representation and knowing them badly, managed to attribute multiple powers to them and submit to many whims that he manufactured from delicate or desperate earthly situations. These representations built in atmospheres of superstition were sometimes operative. They corresponded, in a model, to neighborhoods of comprehension susceptible of a certain operativity. Many wizards must have used these processes.

The gods did not belong to the realm of the absurd. It was necessary to find their coherence in a field of coherence.

We will distinguish between local and global; the local emerges from the global or is immersed in the global by what we call with B. Vivès the decalaires . But there is also the other concept created by Frank Ravatin: the canal. We saw decalaire and canal.

Let us point out that local and global are not exactly tonal and nagual of the Yaqui sorcerer, Don Juan, quoted by Castaneda in his works [5]. The tonal is the protective attitude that an observer keeps <sup>1 2</sup>

<sup>1</sup> This is also how Jacques Breyer's book "Terre Oméga" [4] should be read. Reading involves the way (in a more concise form and which gives the example of such a feeling: the voice is the way!).

<sup>2</sup> The term immersion was chosen by Marc Beigbeder (private communication).

ahead of the global. It's not the local; it is the serenity of belief in the stability of the local at the moment when we look at it, appreciate it, judge it, have the impression of living there. But this serenity is put by Don Juan outside the observer. It is almost a property, a state of the local in relation to the observer; it must be represented as such in order to feel as a surface and interior state, the tonal.

The nagual then is understood as a state of relocation. The observer makes what he wants a witness, and puts this witness either in his representation or attaches his witness characteristics to him and relocates. The nagual is the state of all these operations. This is why Don Juan says that the nagual is creativity.

Let's go back to the local and evolve a bit.

When we speak of local, we must understand that it is an echo of our usual field of coherence that is launched by the observer, but we could have *other "locals"*. In a coherence field, if the space-time structure is present, a room is the echo but to a room does not correspond a coherence field such that the correspondence is one-to-one. From the moment when another field of coherence intervenes which is distinguished by the instability of the landmarks, several representations of the local are possible.

The tonal of which Castaneda speaks is therefore a state of the usual local in relation to the observing human being, but it is also a state of the human being in front of the local, that of the "impeccable warrior" as Don Juan says but that the being attributes to the local.

In reality, these two states are in tension.

On the other hand, in what is presented in this work, there is no separation into *objective* and *subjective*. Nothing that the fact of thinking objective and subjective prevents having access to another representation, another coherence. We break the Other C. of C. to fall into the usual room. We insist on the following point: the Universe is not given a priori and the human being plunges into it. We must understand the Universe as an echo to a field of coherence launched by the observer; the human being launches his field of coherence at the same time as he puts himself inside (which cannot be conceptualized in the world of rational thought). Existence depends above all on a field of coherence. On the other hand, the forms are not immersed in the space-time structure; they are also fundamental by this structure; they emerge from it and more or less immerse themselves in it and do so

that they will be more or less present or more or less absent is manifested by the Eifs and the Champs de Taofel.

The ancients used another mode of thought, which we now express by saying that they projected another field of coherence. This is the reason why their constructions and objects often seem difficult to understand and we classify these objects in the range of aesthetic objects or futilities.

The RBB only understands technical objects <sup>3</sup> (object whose functionalities are localized). J. Ravatin had, as a teenager, sensed that the Ancients had another representation of the world and after he had developed his idea in what he named: Non-Cartesian Systems. In a non-Cartesian system, the feature or features are no longer characterized by the shape, nature and location of the part in the system. Features are outsourced. Such a device, in which certain functionalities are delocalized, is called a “Phenist object” <sup>4</sup>. A Phenist object can even have its components (its components are not subsystems of the Phenist object considered as a system) localized, most of the object escapes us, is not visible to us because it is delocalized. This is the case with perpetual motion machines which have been treated with derision by the scientific world: if we are faced with a Cartesian system, in fact perpetual motion is impossible as well as being of the first kind: it that is to say, to obtain work from nothing (which is in contradiction with the principle of conservation of energy) or whether it is of the second kind: homogeneity does not break by itself (which contradicts the second law of thermodynamics). But if we are faced with a non-Cartesian system, a Phenist object, perpetual motion becomes possible.

To describe the object, its different components is not enough to ensure that we have the whole system and on the other hand to break it down by thought into what we call its components does not mean at all that we are describing the same object.

<sup>3</sup> Functionality: characterized by the shape, nature and location of the part in the technical object (Gilbert Simondon, private communication).

<sup>4</sup> Thus we are faced with three classes of objects:

- Technical objects with all localized functionalities.
- Aesthetic objects for which functionalities are non-existent, s
- Phenist objects of which one or more functionalities are relocated

A technical object can thus be an aesthetic object, just as a Phenist object can be an aesthetic object. But when we go from technical or phenist to aesthetic, we change coherence. In the first case we remain in the usual coherence field, in the second case we change the coherence field.

The Phenist object totally escapes this type of approach. From the moment functionalities are delocalized, the shape that appears is not enough to describe the system.

It is an implicit postulate of the rational way of thinking to believe that by describing a system or its components, we really have the components. On the other hand, in the case of the Phenist object, the principle of conservation of energy and the second principle of thermodynamics can no longer apply: one and the other are two different views of another principle. which could be called the “Principle of Location”.

The rational coherence field develops, throwing into it scales of units: units of length, time, mass, force, intensity, tension, flux, etc. Let us consider the unit of time that we launch into the past: this makes it possible, in the field of coherence, to date prehistoric men from the moment when the problems were posed: the ancestors of man, the origin of man. We have successively found various types of prehistoric men and here clearly appears the concept of existence in a field of coherence.

It should be well understood that by having become aware that by rational thought, by launching the time scale in the past, one manages to date (but this is not the most fundamental).

By dating we realize that everything happens as a creation, which is totally different from the usual point of view. Thus, by going back up the time scale in the past (the unit being the millennium), we manage to recreate in a given field of coherence, here the usual C. of C.; but thanks to the awareness of another C. de C. (Looking at the usual C. de C. allows us to discover the instabilities of this C. de C. and to become aware that we create rather than we do not discover.

We nourish by this process the other C. of C. and also by the fact that we become aware that rational thought is a C. of C.) we create in the usual C. of C. the ancestors and the origins of man.

. The origins are localized as one traverses the scale. From where knowing this effect, by applying it differently, other origins become possible. The great religions are the trace in our local world of another C. de C., they express other origins.

The usual C. de C. can become unstable when you throw unit scales at it. But it is unstable only for the one who is aware of the concept of C. of C., therefore who is in another C. of C. In the usual C. of C., the world is forced to be “fixed” because we think we are observers of the world. By adopting the other C. of C., one is no longer an observer in the rational sense: one projects and one puts oneself at the

times and then there are privileged positions for the observer, taken in the new sense of the word, thanks to which the local will be deformed. The C. of C. underpins worldviews. The Ancients knew all this but in other forms. Perhaps they did not have the language of their C. de C. In our civilization we have the language of the rational C. de C., this is what makes the strength of this one compared to others who preceded it: on the other hand, knowledge is no longer the privilege of a caste but everyone can access it.

The usual C. de C. language was fairly easy to establish because it uses minimal effort to convey an idea; there, the Cartesian character is present, and our principle of minimum energy is the very expression of the usual C. de C. language.

### *//. The Creation of the Past in the Future*

A myth that was very often evoked, and which is still as much is that of Atlantis. All clues to its existence in our C. of C. are the creation in our time scale of the continent and of Atlantis history.

Plato spoke of Atlantis in his two famous dialogues: the “Timaeus” and the “Critias”. We will not return to these texts, they are sufficiently well known; many works have quoted them and reproduced passages. Atlantis, on the other hand, has been located in multiple places.

Is Plato's story symbolic? Or is it a legend? Or a legend that embellishes older events?

In the “Timaeus” and the “Critias”, the author attributes to the story told to Socrates what the priests of Sais told Solon, legislator of ancient Hellas, who traveled to Egypt around 560 BC. The assembly of priests of the goddess Neith of Sais, protector of science, would have revealed to Solon that in archives, which dated back millions of years, there was mention of the existence of an immense island the size of a continent, located beyond the Pillars of Hercules and swallowed up by the waters after a sudden catastrophe. - This can be seen as the expression of a story but also we can create and "suck" this story.-

In the course of this same account, Solon learned from the priests of Sais of the existence in Athens of a State which, having been attacked by the kings of Atlantis, had victoriously repelled these invaders. But, shortly afterwards, an unforeseen and brutal catastrophe engulfed the island in the waves.

This dialogue from the *Timaeus*, in which the plot of the history of Atlantis appears, also touches on astronomy, the science of numbers, musical harmony, philosophy and religion. This is how we can place this engulfment of the island-continent at approximately -12,000 years from us.

The second dialogue, “the *Critias*” focuses on the general and physical geography of Atlantis. Plato relates that in the center was a fertile plain protected from the northern winds by high mountains. The climate there was more than tropical and the inhabitants could harvest two crops a year.

This second dialogue mentions the details relating to the capital: buildings built in red, white, black stones; large temple dedicated to Cleito and Poseidon, decorated with gold ornaments, walls covered with silver, golden enclosure that surrounded the temple near which the ten kings of Atlantis gathered at various times to perform the sacrifice of the sacred bull, previously captured by means of a net <sup>5</sup>.

Of course, we can say that it was Atlantis that influenced Europe, Asia and even America and this has often been invoked! But that remains a rational explanation, of the usual C. de C..

In addition, trades, industry, science flourished in Atlantis; there were many ports, canals and shipyards. The commercial relations mentioned with the outside world affirm the maritime vocation of Atlantis and suggest to us the use of boats capable of crossing the ocean. The 1,200,000 men in the army, a considerable number, oblige us to admit the existence of a high population - if we stick to the usual point of view -.

Plato did not make the mistake of confusing Atlantis with the Americas: “Another continent was to the west of Atlantis”. He speaks of the ocean beyond the Pillars of Hercules (the current Strait of Gibraltar) and says that the Mediterranean is only a port... It is in this Atlantic Ocean that he places an island -continent larger than Libya and Asia Minor combined.

Very lively discussions have taken place about these stories. They had their origin in an article published in the “*Mercure de France*” by Professor Couissin which tended to prove the mythical character and the absence of scientific basis on which the hypothesis of the existence of Atlantis rests, this article claiming that it was, in fact, only a mystification. For archaeologists, the existence in the past of a link between the “Old World” and the “New

<sup>5</sup> We find the sacrifice of the bull, the rites and ceremonies dedicated to the cult of Mythra widespread in Europe and Asia.

World", would make it possible to bring an explanation to an irritating enigma: namely the astonishing analogies which one can discover between the Egyptian and pre-Columbian civilizations, that is to say rites, adoration of the Sun, pyramids, use of a ternary symbolism. But these resemblances do not hold, let us point out immediately, if we suppose that these civilizations drew from the same source which is in the process of being primed by emissions due to forms. On the other hand, the ternary symbolism is also found in China and also whenever an archaeologist somewhat versed in occultism has approached an ancient civilization.

The search for the position of Atlantis has given rise to countless possibilities. Commentators faithful to Plato's account support, for their part, the position of Atlantis in the Atlantic Ocean and more precisely the Canary Islands and the Azores would be emerged vestiges but on these islands there remains no trace of Atlantis ; they are still quite small. While the others locate it in the most diverse regions, Greenland, Ireland, Heligoland Island, the Atlas, Mongolia etc.

Other rather singular thesis: Atlantis would be the moon torn from the depths of the Pacific. It is curious that the authors of this idea did not compare the radius of the moon to the greatest depth of the Pacific which is about 10 km.

One can retort that Rudolph Steiner had supposed that the moon was born from the earth and certain followers of the creator of Anthroposophy support this idea without thinking. It must be said that R. Steiner, in his visions, could have arrived at such a conclusion, but this should not be taken as a scientific truth but as a means which makes it possible to arrive at other conclusions which are useful. The Master Philippe de Lyon had also seen, by duplication, multiplicities of suns behind our sun... likewise, he gave rapid visions to people who asked him questions: this could only be of a symbolic nature or even of the kind unimportant vision, usable perhaps (because it had been given at a given time), in an astrological chart or something else [7].

Likewise Edgar Cayce and many others. Likewise interpretations of clairvoyances like those of Catherine Emmerich and others, where dates of events are given. These dates do not fit into the calendar; they are the clue that the event to come could be datable.

The hypothesis of Atlantis submerged in the Atlantic Ocean meets with the greatest number of votes. In France, two men of Science attached their names to this thesis: Pierre

Ternier, permanent secretary of the Academy of Sciences and Louis Germain, assistant at the Natural History Museum [8],

The study of the bottoms of this ocean shows, in fact, that at a certain time, the shores on the American, European and African sides were much more advanced in the sea, while there is, in the center, a plateau under-marine, the depth of which does not exceed 900 m. constituted by the Azores.

Pierre Temier gave a lecture at the Oceanographic Institute in 1913 in which he supported this thesis. Vulcanologists are against this thesis. They claim that the continental plates, by their positions and structures, do not allow at all to affirm the existence of the famous submerged continent. And we arrive at the hypothesis of the explorer Rebikoff who, by his underwater dives, was led to think that certain pieces of Atlantis would be near the Bahamas, which Edgar Cayce had also seen in clairvoyance. Rebikoff settled in Florida and proceeded, aboard a small seaplane, to reconnaissance in order to find submerged sites (this technique was perfected in the Mediterranean and gave surprising successes). He flew over bodies of water in the Bahamas archipelago and the appearance of a simple geometric shape, thanks to the transparency of the water, struck Rebikoff: in one case a room, in another a gutter of 550 meters long, lined with walls cut into the rock.

Testimonies reported by divers such as Pierre Carnac report enormous walls, for example those of the island of Bimini, oriented northeast, extending over several hundred meters in length: they are made up of blocks of 5m x 5m and 50 cm in height. The weight of each block is 25 tons. These blocks are bound by a dry cement, which suggests that these blocks were assembled on dry land. Techniques and materials can approach what has been observed in ancient Mexican temples. The dating is difficult to establish. It was evaluated at -4000 years. The remains would therefore predate the Olmec civilization, one of the oldest known in pre-Columbian Mexico [9].

But a curious fact was reported to Pierre Carnac: the fishermen of these waters had never seen these submerged constructions before their recent discovery by divers. Of course there were the aerial views, but others, as P. Carnac has confirmed, can be distinguished by a simple boat trip in calm weather. It therefore seems that these walls are localized. Our classic notion of existence is based on the past, the present, the future. Time is seen as the number line, even topologically.

But time can have what we called cumularies <sup>6</sup> or decalaires<sup>ô</sup>, either related to the obs, or related to certain observers (i.e. for an epoch a cumulative would exist in the past but not for another time). In paleontology, the theory of evolution is placed on the usual time scale. In Paleontology we begin to sense discontinuities there. These are only the index of an imperfection of the system of projection of the time scale.

Notes :

- 1) The decalar only exists because a neighborhood has been created; we set up the decalar which makes pass from the global to the local and vice versa.
- 2) This representation makes it possible to compensate for our impossibility of immediately observing the global and on the other hand makes that in our localization error, we create an operative representation. The human being, even from error, must always derive a truth (truth on his own scale). It is redemptive death in life. It is the manipulation of archetypes for those who have not understood. It is the stopping of the race and the sublimation of those who want to be gods. It is the dilution in the solvent that will become a decalaire. It is homeopathy at the level of form. It is the disappearance of the level in favor of plenitude. It is the outside of concepts.
- 3) We must not forget the privileged position of the obs. Obs is the origin of landmarks.
- 4) In a work by HP Lovecraft and A. Derleth [10] we find this: "We must congratulate ourselves, full of gratitude, that the human mind is incapable of establishing relations between the various elements of the Universe. We live on an island of ignorance, in the middle of black oceans of infinity, where it is not given to us to venture very far..."
- 5) The arrangement of the more or less localized forms of the Local plunges us back into delocalization. All these delocalizations, starting from the more or less localized, constitute leaks from the Local to the Global. These are the ones that are most easily accessible to us.

<sup>6</sup> Cumular: term coined by J. Ravatin (see previous booklets).

Décalaire: term coined by B. Vivès (see previous booklets).

Reminder : These concepts were developed by these two researchers around the years 1963-64. They didn't know each other. Initially cumulative and decalar had about the same meaning too, when these two researchers got to know each other and exchanged their results, they decided to keep to decalaire the first meaning given by B. Vivès and to cumulative, the meaning of flight markers but followed by a new catch-up of these markers. Note that the definition of decalaire for B. Vivès was purely mathematical. This was taken up by Ravatin in a more physical context and slightly different in meaning from what Vivès had axiomatized.

By making this hypothesis, don't we suppose that we can judge without any notion of time? Do we not place ourselves as a privileged observer in relation to a possible observer? If we consider it in this way, we arrive at Dunne's "serial time" [11]. It is a recursive process. We will not focus on this point of view because it is absolutely artificial and this tendency to construct the observer of the observer etc. indefinitely, is not a correct observation of oneself but an illusion which leads us to judge step by step, therefore to being unable to escape localization. Any process which involves the infinity of the numeration or which is in one-to-one correspondence does not correspond to a correct process. Nature does not work that way. We can, to describe the rupture or the evolution of a phenomenon, choose a model which does not copy reality point by point, but we must be wary of the model in which we introduce a method which imposes the C. of C. usual. We will endeavor to present a new notion called *the creation of the Past in the Future*<sup>7 8</sup>.

We must not forget the privileged position of the observer. The observer is the origin of the landmarks. He launches his markers and these, in a given C. of C., generate a reality because there is coherence. Thus all the indices of Atlantis, the texts of Plato and all that followed since Plato until our time, make that Atlantis is appearing and, when it will be there (will have been found -on in the rational C. de C.), we will find in it all the clues of its disappearance approximately - 12,000 years ago. This process enriches the room. Edgar Cayce described Atlantis in a more or less folkloric way in his "readings". Thus another existence is profiled which will come to converge towards the usual existence, the latter realized on the number line.

<sup>7</sup> Notion devised by J. Ravatin. Let's complete this paragraph by adding that the notion of infinity applied in physics imposes localization. A model is not forced to follow a phenomenon step by step, but certain parts of a model lead to a C. de C.. S. Luspaco introduces the transfinite instead of infinity, which corresponds to it. physical intuition of infinity.

<sup>8</sup> This point of view should not be opposed to that of relativity. In relativity, the observer corresponds to the point of view of the physicist. The notion of consistency is not considered.

This diagram should be understood as follows: the IR line is that of the flow of time according to the usual point of view. The curve (C) has meaning only for the observer O who is the origin of the time scale that he projects into the past.

When Edgar Cayce was, by his doublings, observer, he saw because he placed himself in A intersection of the vertical in O and the curve (C) and the tangent in A intersecting the line IR in T gave him on the axis O IR, the spawn point of Atlantis (on the time scale). Thus, he saw the reappearance of Atlantis in T but for him, it had disappeared -12,000 years ago because he participated, without knowing it, in its relocation. The date at T was only valid for him because the curve (C) was his.

This curve has no origin; it is constructed by the observer O<sup>9</sup>. In reality there is only a point A and a line AT which gives approximately, for O, by accumulation of proofs of a past existence (but which never took place) a creation on IR around T.

What has been said for Atlantis is also true for the Mu continent mentioned by Churchward [12].

In the creation of the Past in the Future, what becomes of the events attached to what is usually called (and this in a relative way) the near past? Let us take the case of his parents, his grandparents, his great-grandparents<sup>10 11</sup>, those whom we knew and who disappeared, those whom we did not know but of whom we have heard because their relatives knew them.

This is where the immersion of stabilization takes place; that is to say that, in this near past, we have a kind of extension of the notion of present (and the absolute present is felt only by the near past)<sup>11</sup>.

<sup>9</sup> She emerges from a decalair.

<sup>10</sup> To all of them, they constitute a channel.

<sup>11</sup> The notions of near past and absolute cannot be defined separately. The absolute present is felt as a limit of a period of time. The advantage of talking about the recent past is that there is no fixed limit; it is a feeling.

Time is counted down through a recursive process. We perceive two notions at the same time: what we live and what we project (here the time scale) and the scale originates from the lived moment. This is how they are connected.

But you have to reflect on yourself and ask yourself what you think when you accept the usual point of view. These supposedly recursive systems carry with them their own destruction. Is it due to nature which refuses recurrence, or to our intellect which itself breaks its model? The two answers are not both positive and negative, or mutually exclusive, they are in dynamic duality.

We have seen that in paleontology, we launched a time scale: - 10,000 years, - 20,000 years, ... - 100,000 years, ..., - 500,000 years, - 1,000,000 years ... We arrive at - 2,000,000 years and this to find the origins of man. One finds skeletons of human beings of "older and older". The first skeletons found in the 14th<sup>century</sup> were - 30,000 years old; now we are at - 2,200,000 years!

The cumulative is a flight of benchmarks followed by a resumption of stability of these benchmarks; like the decalaires, they are definitive escapes. In these cumulative localizations will be able to be made, which will be stable in general. Thus we create the image of the past thanks to the past. In paleontology, we go from one human type to another older human type (which we will define a priori or during research) and we go back in time thanks to the time scale. These two combined scales: that of the human type plated on that of time will give the creation of the past in the past, to make discover the origins of the man, his way of evolution. In the usual C. de C. the observer is absolutely unaware of his privileged role of origin, of launching ladders, of

<sup>12</sup> This process is not recursive; that is to say that the creation of the past thanks to the past is not done by the past. So let's say that:

Any recursive system is to be rejected but its use is operative in the sense that it creates what is sought.

We find ourselves, in Paleontology, in front of a creation of the past in the past.

Scales are attached to shapes; they are not separable from forms. The number is intimately linked to the form, "the number is the form" said Anaxagoras.

The human being is a form, the living beings are forms and the time scale associated with them will be more or less compatible; it will bring out certain beings who will be an image of the abstract human-being entity with modern man as its origin and a localized vicinity of man - 2,000 years to - 5,000 years (but without precise limit).

This neighborhood is not separable from scale and is not separable from past, present, or future discoveries about the human race. Nor can it be said that this neighborhood carries everything within itself; it is a facet of a notion that cannot be represented to us.

superposition by plating of 2 scales, of neighborhood, and especially of cumulative. Thinking in the other C. of C., we see that the overly simplistic and inadequate models of the rational approach are trapped by nature which returns what we are looking for as long as it is coherent. with the rational (but this is understood only from the moment one possesses the concept of C. of C.). This action in the rational (i.e. creating the extension of the model, at the neighborhood level, provided for in the model by applying the model to reality), applying the human representation, from its swelling to no longer being able to be accepted by the real, causes the cumulative to burst; a new older skeleton appears and so on.

We should not ask the questions: "what if we had not dug at such a time, at such a place?" or, "Was the skeleton there before we dug?" ". These questions don't make sense. It's absurd. The absurd is not the equivalent of negation. There is the yes, the no and the absurd. Creating indeterminacy between the yes and the no, or even fabricating Logics with discrete or continuous values (like certain works carried out by Poles in mathematical Logic) does not bring in this third possibility which is the absurd. Gérard Cordonnier had understood this very well when he advocated in his lectures (begun in 1933-1934 and conducted until his death in 1972) a logic with three values: the yes - the no - and the third which he called the "damn". In reality this "damn" is the absurd. The human being carries the absurd within him. This is where the Judeo-Christian religion put the entity Satan, which can also be a state. The usual C. de C. does not correspond to the absurd but it can lead to it because its strength is also its fragility.

Let us point out that mathematical logic considers this third term as an abuse of language and takes care of tracking down but an axiomatic in physics has almost never been formulated to account for such a vision of the physical world.

We are faced with the partial acceptance of a model or models placed, by the mind, on Nature. This model allows us to bring out another vision of Nature, even if it is not correctly understood and it is here that we will say that the model is operative. Nature is not silent in the face of questioning: it is active (it is the usual representation substituted here for our new representation which makes us express ourselves in this way).

In the classical point of view, discovery comes down to discovering and placing in the time scale. In the other point of view, it is the time scale that launched created what we find: the discovery leads to an emergence due to the acceptance by the Universe of a time scale, as it can lead to the emergence of the operability of a device and when this operability has

taken place, it can be resumed as many times as desired, as when the skeleton of a type of prehistoric man is located, it is there for everyone.

We are faced with 2 concepts: a present and one of its neighborhoods and a time scale; and it is classically assumed that this neighborhood can be arbitrary and that such neighborhoods can be constructed which will be able to contain the time scale. This is precisely where the shoe pinches. A neighborhood serving to spawn a ladder cannot swell out of proportion until it encloses that ladder.

From the moment when we suppose the recurrence to be unstable, that is to say possessing in itself its own destruction, we cannot therefore pass from a near past to a too distant past. A time scale isomorphic and homeomorphic to the line of the real numbers is not correct but its false character will be operative and allow entities to emerge which will more or less be placed on this line.

Hence these skeletons found, old by our arithmetic, about 1 million years, are creations-responses to our usual mode of counting.

This time scale is creative as can be a technical object repeated in a large number of copies because from the (non-fixed) number emerges a new entity, not localized, which can in certain cases be localized. This number (not fixed) is not a number but cumulative or a shift.

The concept of being-human-supposed-to-have-had-an-origin, and therefore similar to us (we admit slight differences and by continuity in time we arrive at very strong differences) constitutes an origin and a neighborhood thanks to which we will be able to launch a scale that will generate a type of representation <sup>13</sup>.

passion of the 20th century

<sup>13</sup> We should not deduce from this that the process will repeat itself ad infinitum.

it is bondage. »

Albert Camus

Albert Camus 1913-1960, born in Mondovi (Algeria) French writer whose work depicts meticulously, in all its aspects, the absurdity of the human condition to which it opposes the revolt which presents itself as a will for each man to fight relentlessly against the inhumanity of his temporary situation in the world and to push back its agonizing limit. He was awarded the Nobel Prize for Literature in 1957.

### Exercise :

Let's take a sharpened pencil.

- 1) Check that, placed on a table, it emits from the tip the eif - at the EFF level - resulting from its orientation. This eif is in the aura spectrum.
- 2) A naturally polarized plywood disk is placed flat on a horizontal table.
  - a) Check that a sharpened pencil, oriented along a diameter of the disc and which slides along the diameter causes the SF to emit.
    - when the tip is flush with the perimeter of the circle, the eif of the tree trunk, for example in IR
    - when the tip is between the radius  $R$  and  $y R$ , there are only SF polarities but no eifs.
    - when the tip is between  $y R$  and  $y^3 R$ , an eif of the aura is observed at SF
    - when the point between  $y^3 R$  and the center of the disc, we find the eif of the undifferentiated spectrum, for example as at the beginning, the IR.
  - b) Check that by placing a ring flat on the disc, in the center of the ring, we detect what made the SF emit the assembly with the pencil.

The ring, on its axis, emits the node of life.
  - c) Check that by placing a needle in the center of the disc - which is always pierced right through - and whose end is directed at a right angle, therefore following the vertical and downwards, following its length, the eif qu' it causes is one of the above.

Consequence : The searches are equivalent to the internal exploration of the tree trunk.

It might be interesting to repeat them on a freshly felled tree stump.

### Notes :

- 1) A monument, an arrangement of space, any object whatsoever must behave, if possible, like a living being which has grown, from an initial point, from a germ, according to certain laws and not in chaos .

At the EFF level - if we leave it at that - we must take into account already known factors which can be used for the development of the plan, but also for verifications of the conformity of the plan with a field that could be called "balance ".

We may not be interested in the EFF level and approach the C. de T. and their flight, then what we have sometimes mentioned - but which is not yet treated - the eifs such as VC, FV etc.

Let's see an exercise:

Exercise :

We start from the circular plate, emitter of the eifs at the EFF level, eifs of the undifferentiated and differentiated spectra.

Grooves are engraved along the radii at  $198^{\circ}.5$  and  $108^{\circ}.5$ . One inserts in these grooves starting from the center of the disc - one will be very careful not to block the central hole - copper wires, rather short, whose one end begins at the center of the disc.

Check that whatever the position of the needle, nothing is detected at  $V + M$  but that C. de T. are detected around and above the plate.

- 2) Directed electric or magnetic fields emit eifs according to their orientation. Contrary to what one might think, the positions of the needle on the circular transmitter plate at  $198^{\circ}.5$  and  $108^{\circ}.5$  do not make it possible to emit specific eifs of these fields, that is to say that the eif emitted at  $198^{\circ}.5$  does not correspond to the eif of a magnetic field and that at  $108^{\circ}.5$ , the eif of an electric field. The perpendicular of these 2 positions has nothing to

do with that of the E and M fields of electromagnetism.

- 3) The eifs of the circular plateau at  $198^{\circ}.5$  and  $108^{\circ}.5$  are not perpendicular to the square emitter presented in the course of the <sup>st</sup> level.

## Chapter XIII

### *1-Feedback on concepts already considered*

We have seen in the case of the pyramid of Cheops that the Ancients should not have imagined it as we see it now because they thought otherwise and had access to notions which have disappeared in the usual C. de C..

This is why we created the concept of the EXT of the Cheops pyramid, of the EXT of a form.

The ext is completely relocated; it is linked to the global.

We had left as an exercise the care of showing exts to certain shapes, for example cube, ball that we pierce or on which we fix thin rods; the holes must be small in diameter compared to the volumes considered.

A crystal always has an ext.

A living being - plant, animal, human being - always has an ext; if he doesn't, he's sick.

A human being who is born without an ext - this rarely happens - tends to live as a parasite on the people around him. He needs a neighborhood and he will cling to a presence of this neighborhood: curiously, a human being who is born without ext and who is weaker in intelligence, will succeed in being accepted by blinding those around him, to get help, adoption and to the detriment of those who will take care of him all his life.

These cases are usually detected by doctors - they don't interpret it that way at all - but there is not much they can do. Psychiatrists sometimes try to intervene, but they only displace the anomaly, ie the patient seems to have evolved a little while he keeps his parasitic attitude. All attempts using forms to give the patient eifs and to make him disappear from the harmful state (in the eif sense) in which he is, are also unsuccessful.

We have also seen the concepts of primer and progenitor in the case of the open forms where they were presented.

Many forms have progenitors.

Ext and spawner are quite different.

A human being may not have an ext but he has a progenitor - who is not in general the one who generated him -.

Consider two miscible or immiscible liquids.

We can give an ext to the mixture even if none of the starting liquids has one, from a volume  $V_1$  of the first and a volume  $V_2$  of the second.

A liquid can take on an ext after having plunged into it in a suitably chosen solid, or after having been illuminated by electromagnetic radiation of precise wavelength and frequency, or even after having circulated in a specially shaped pipe.

An oil, regardless of the container that contains it, has no ext, but has a parent.

We managed, after various treatments, to give it an ext by loading it with eifs - this for all vegetable oils, even those treated by chemical processes -. For silicone oils it is more difficult but we have also succeeded. It is also possible, in certain cases, to circulate these oils in pipes of special shapes and at certain temperatures, then an ext appears. This ext, in all cases, is stable over time, by heating or cooling. On the other hand, if other products are introduced into these oils with an ext, this may disappear.

A comparative study is carried out in [1] and [3] to distinguish ext and parent on paintings by painters, ancient monuments, musical instruments.

The work of J. Ravatin and AM Branca can be obtained at the address 76 rue Didot 75014 PARIS - Tel. : 01.45.42.58.72 (and volumes III and IV of Vladimir Rosgnilk's work at the same address - mail should be sent to Mrs. Branca).

It may happen that different forms have the same progenitor.

A shape like the labyrinth of Chartres Cathedral makes it possible to act on the originator of a shape; itself has a parent.

A natural or chemically treated oil has a parent. It is not the volume of liquid that gives it. A silicone oil has one. A transistor has a progenitor but when it is

mounted in a device, its progenitor disappears to enrich that of the device. A crystal has a progenitor and when it is mounted in a device, it generally keeps this progenitor.

The organs of a living being have no progenitor because they are organs that are like cut-outs from a too rational view. They become too localized, which in some cases can bring instability to the room.

## Chapter XIII (continued)

### */ . Consideration on achievements [1] and [2]*

Cathedrals have exts, churches too. A dwelling house, in general, has no ext.

The ext in this case is to be avoided. Living day and night in a house that has an ext can lead to transfers between this ext and the exts of living beings in this place. We no longer control anything!

We can study other monuments. This is left as an exercise.

All the great castles have not been reviewed. On the other hand, the constructions intervening in what are called large ensembles must rarely have either ext or parent and even more rarely both. The large complexes have been baptized by the promoters, to attract the client, residences. But these are absolutely not residences in the sense that it was still understood 60 years ago. These residences had for some an exterior that was impregnated with the neighborhood: trees and woods surrounding the residence. Architecture, as J de la Foye pointed out in his book [3], is taught and applied indiscriminately; especially since the 2nd <sup>World</sup> War (for lack of housing due to massive destruction), which allowed the horde of promoters to grow in number and power and to drag in its wake many architects who are not able than drawing cities without souls. In these aberrant constructions, made on places that have not been studied for their eifs, there are also very often harmful eifs and even harmful states. R. de Lafforest drew attention to this issue in what he called "The houses that kill". Harmful eifs are also found near high-voltage lines: a 100,000 volt line is surrounded by a V'E SLEEVE APPROXIMATELY 80 meters in radius. A line of 200,000 carries in V'E up to 170 meters; a 400,000 volt line up to 350 meters. It is easy to check with a pendulum or rod that the "intensity" at V'E does not decrease with distance but remains more or less constant and falls suddenly. It is this V'E which is responsible for many disorders affecting people living under or near high-voltage lines, the electric field between the line and the ground being much less harmful than the V'E.

A research group has been set up in France which is studying this form of pollution and trying to remedy it. This group is called ARKOLOGY. He is particularly interested in the field of investigation of geobiology but while geobiology tries from points of view Level 2 Fascicule 18 23/01/2012

rational to restore atmospheres which at the beginning are harmful, Arkologie takes again the approach given by the group ARK'ALL and applies it to the habitat, but extends it to a much vaster field which is the architecture in general, and even more to Art in all its forms. Extensions of the views of this group are considered in allopathic medicine, homeopathy, acupuncture, anthroposophy, etc.

A company, BARKA,<sup>1</sup> was also created.

In architecture, it is not enough to test a house piece by piece to list its eifs and states. The house can be considered as a whole and then eifs and states are other than those of each room. Those who live in the house are in contact either with the emissions of a room when they live in this room and in their representation they place themselves in this room, or with the emissions or the states of the house considered as an entity when they think of their home. All depends on the representation and let us repeat it once again, it is one of the reasons which makes that the dowers, when they lean on the places, do not find the same thing; the representation of what they are looking for and their definition of the place they are testing is not the same for everyone. It is necessary in architecture to bear in mind what is represented in order to announce the results of these tests according to the chosen representation. We can therefore, if we study a house, represent it as the assembly of its rooms, or as a unit, the hearth where a family will live, or even the house and its close neighborhood as indivisible. Can we continue to expand? We would thus have the house and the department or the country etc. It would be absurd to continue such a recursive process and it would be to misunderstand the approach that we have been trying to give since the beginning of this course. From a certain moment the concept of house and more or less large neighborhood will flee, and if we want to find eifs and states of it with such a unity: very large house and neighborhood, we must take flight into account.

Naturally, the eifs and states of the rooms can also depend on the forms that are there, that is to say the furniture, the paintings hanging on the walls or the arrangement of the furniture. Example: seats by their shapes, their respective positions and places in the room, can for example have a harmful state or cause a person sitting in an armchair, because it is a seat

<sup>1</sup> ARKOLOGOGIE and BARKA can advantageously be contacted and consulted for the construction of dwelling houses: here are the addresses:

ARKOLOGY: Mr and Mr Hennemann 77 rue de la République 93200 Saint Denis Tel. : 0142 43 05 14

BARKA: Mr Labat and Mrs Nouvel 31330 Launac Tel. : 05 61 85 77 76

often massive, will be overlapped while she is seated, by another person placed in another armchair according to the provisions previously indicated.

We see that the architect and the decorator have a serious job to do before playing with the shapes. Lafforest and La Foÿe have insisted enough on these points in their respective works for us to come back to them. However, they did not consider what we have established: the exts, overlaps, the study of the house as a whole, etc.

Nor should we make too hasty systematizations here: for example, any clogged well, still containing mostly stagnant water, emits harmful emissions vertically from the well, in particular a strong V'E- We have been able to observe such wells in the gardens that had no such harmful emissions at all, yet clogged, and with stagnant water inside; of course this is not the generality. We even found a clogged well covered by a house and there were no harmful emissions in the rooms or in the house as a whole. Maybe the shape of the house eliminated harmful eifs? There were also no harmful states.

It happens that in the study of certain places it is difficult to test. There can be a grid, then with the help of appropriate shapes we raise it; it can remain up or recover as soon as the forms necessary for the test are removed. This grid can be a protection for those who approach the place, it can rise as soon as the inhabitants of the place present themselves, finally many possibilities arise between the grid, the inhabitants of the place and the foreigners. When one finds, after having raised a grid, harmful states, if one does not know how to eliminate them it is necessary to put the grid back in place. It is sometimes difficult to eliminate harmful states; most often we don't know how they got there, and if moreover there were intentions, we don't easily know what these intentions contain in terms of possible surprises in order to avoid "return shocks". It may be that there is no grid on the place, but that the place, the dwelling are in transfer with another place. This case occurs quite rarely but it must be detected because there is no point in putting a rebalancer to eliminate harmful eifs if there are any. The place with which the transfer occurs can be near or far. While working on a plan, we sometimes went beyond the limits of the layout plan and therefore did not know the location of the house under study. In this one the people who lived there could not sleep, they really did not feel at ease. By putting on a very good rebalancer (and there are few good ones) they slept very well for three nights and then everything went back to how it was before. There, a study made by A.Grangé and J. Ravatin led them to discover this transfer and the rebalancer had to rebalance the place about 800 meters from the house with which the transfer was made. He deleted

for some time certain harmful emissions from the house, because it momentarily broke the transfer, then last reforming, the rebalancer was no longer useful. It would have been necessary to increase the power of the rebalancer, by increasing for example its volume, its mass or the electric voltage on which it was connected but it is always boring to have in a house devices connected to high voltages. In this specific case, A. Grangé and J. Ravatin had imagined 2 copper shapes, one placed in a dining room and the other in another room, which broke the transfer and then the rebalancer gave its full effect.

Regarding rebalancers, multitudes have been made since Turenne. Let's say immediately that there is no universal rebalancer and that few are valid because many people who make them know little or nothing about eifs, or if they know them, they neglect states; it came to our knowledge a so-called rebalancer made by two people having understood nothing with the eifs, which eliminated sometimes some harmful eifs but created almost each time that it was installed in a house of the extremely harmful states; this device in addition was sold quite expensive which did not help. In this case, to make such a device harmless, it is best to put it in two well-closed plastic bags and then it can be placed in a closet or cellar, it becomes absolutely neutral. We must also be very careful about this: any form has given eifs in a certain volume, by this volume, there is a threshold below which the eifs and the states can change completely. So you shouldn't put a rebalancer in too small a volume if you want it to work well.

We were able to observe another kind of rebalancer which, although it eliminates some harmful eifs, begins to have a completely harmful state throughout the room where it is located as soon as it is placed in front of a mirror. Naturally the seller, when he was told this major inconvenience, didn't care.

If we come back to less dramatic cases<sup>P</sup>, let us nevertheless point out that it would almost be necessary to study the rebalancer for the place. Finally, some rebalancers, which are also transmitters (there are very few of them) can intervene effectively in a large number of cases. It is also necessary to be careful that some become "saturated", that is to say are no longer effective after a certain time of use and this without there being grids which appear. A rebalancer which becomes saturated, it is enough every eight days, either to pass in running water if it is of a material easily supporting this treatment, or to brush it vigorously etc. Rebalancers must be oriented, for others it is not necessary. The shape called "Luksor" must be oriented to the north of the shape, but this orientation depends on the place, or the size of the room where the

form. We were able to verify once that this localized form had to be oriented every day because its annihilating power of harmful eifs varied with the phases of the moon; This presents very delicate forms of manipulation. It is difficult to make a rebalancer that does not depend on orientation; it must be thought of, during its development, so that it is easy to arrange it in different places. It should not saturate. In general, you should not place a rebalancer-transmitter on a television set because its transmitter character disappears and if it is a rebalancer alone, it may very well no longer rebalance anything (a black and white television set sends a V' E at 6 meters and a color post at 8 meters; this was found by A. Philippe). On the other hand, a rebalancer can be placed on a television set if this has been thought of during its development.

It is a good idea not to place the rebalancer near the ceiling of a room, nor at floor level (except in a few special cases). Nevertheless, when possible, it is preferable not to have to put a rebalancer. Indeed, if the owners of the house move and take their device and if the environment has not changed, everything becomes as before. Architects therefore have advantages in studying the place (basement, more or less close presence of high-voltage lines, transformers, terminals, finally what all our modern world brings), on plan to take good care of the forms ( parts, framework, air and water ducts) of materials, to avoid pyramid-like shapes for example. They are not always harmful but it can happen because the house built in the shape of the pyramid of Cheops is not at all like the pyramid of Cheops internally, neither on rocky ground, nor even if it is oriented like the pyramid of Cheops , with the different environment, different materials, harmful states may occur and even transfers with other places.

A Mexican architect won at the age of 47, in 1971, the first prize in the competition for the Hervico Colegio Militar, the Military Academy. The largest project that he has realized so far constitutes with the 90 million dollars that its construction cost, one of the most spectacular and ambitious architectural projects of this booming state that is Mexico. Christophe Bürkle [4] quotes "Having not been the subject of any report up to now - it is a forbidden military zone - the Academy represents one of the best examples of the ambition to which the modern architects: the synthesis between the tradition inherited from an ancient past and the functionalism of the modern era". But this mixture is not at all necessary. The old forms corresponded to very precise needs which were not those of work rooms in the sense that we understand it, of dwellings (example of the famous pyramids of Teotihuacan). The construction of this architect includes a

few V'E and JE in places but there are no harmful states. (The V'E comes out through certain oblique openings, its intensity varies with the position of the sun). The buildings built in a large plain surrounded by mountain ranges are beautiful. But we must not generalize this habit of making pyramids or other imitations of ancient constructions while the architects who embark on such achievements know absolutely nothing of these civilizations in the most important field which is that of religious practices of the past. . Philology is then necessary and not yet philology in the sense that we understand it but in the sense that Louis Boutard - Louis Boutard whose immense works will be presented in the 3<sup>rd</sup> level course - understood and applied it.

It's not because in the more remote areas of the Yutacan you can find coca-cola and hamburgers and the Indians who through the cities buy plastic anoraks in the department stores and slowly unlearn to dress according to the tradition of their fathers (they no longer even know how to use the old looms), which it is necessary under the pretext of putting people back in contact with their so-called origins, building dwellings, factories, libraries, shapes reminiscent of ancient shapes. It's just another joke. We still find this in the frescoes, paintings, sculptures, executed in the "Indian" style which adorn a good number of buildings in Mexico City. They reflect a failure to integrate folklore into architecture. We come across forms that no longer agree, no longer marry, because they belong to different eras and worse still, they are a mixture of antics of one era with another era. Back to Hernandez: abroad, he was especially noticed thanks to the Mexican pavilion at the "Expo" in Osaka, Japan. He reached, according to the point of view of many so-called modern architects, his best technical performance with the tower of offices and workshops built in Bosques de las Lomas, a suburb of Mexico City. He imagined a form of crossed double pyramids and for this he was inspired by the pyramids of Tulum and Tatin. This realization of Hernandez is interesting from the mechanical point of view, resistance of materials. In the 36-meter high tower are the stairwell, the elevator, the rooms necessary for supplies. This tower itself constitutes the support for the double pyramids which intersect and are themselves supporting elements. In conclusion, we absolutely do not use forms adapted to civilization, linked to other forms solely for mechanical, utilitarian and aesthetic reasons, whereas the primordial concern of the ancients, which was that form be an approach towards the delocalized, is not respected at all. Harmful emissions may occur,

even harmful states, pollution of the place or of nearby or more distant places, all this is possible and is completely neglected.

About the Military Academy of Mexico, built in 400 hectares of land, we are far from the notion of sacred place of prehistoric centers such as the sacred place of Teotihuacan in which we find large expanses surrounded by mountains and this not in a goal of natural defensive wall as the architect thought and aped when drawing the plans for the F Académie Militaire.

Of course it is not forbidden to copy forms, to impose functionalities on layouts, but above all they must not be justified by a pseudo-attachment to the past (the architect expresses himself: "We are aware of our historical journey. We must break the imbalance that exists between our own sensitivity and the foreign forms that reach us. Mexico has a cultural heritage that we have no right to squander, because the most important thing for a people is to preserve its fundamental characteristics). By taking initiatives of forms from the past, we can, as they have not been understood in our modern civilization, generate unexpected phenomena of the kind transfers with the past, but with deformations such that very harmful states are installed by times and this in an absolutely unpredictable way. The misunderstanding of the achievements of the Ancients is too great to try to use, aping what is left of it even purely for decorative purposes. It is not because architects, for the most part, are devoid of ideas, no longer have inspiration, that they have to gargle with phraseology to justify their mediocrity. When inspiration no longer blows, speeches do not replace it. Thus triangles, parallelograms, polyhedrons, prisms inscribed in gigantic cubes, succession of pyramidal blocks, use of decorative motifs from Teotihuacan, as well as motifs from the Maya and Toltec civilizations, create a dangerous disorder. And when Hernandez or his admirers and journalists in search of articles speak of the "magical reality of his work", they do not suspect that in these achievements, there is truth in a sense that they do not imagine: magic can appear and where does it lead?... Human beings do much more than they believe when they realize. He must pay attention to this.

With architects who call themselves modern, we find ourselves in a situation where we take a piece of Chartres cathedral, a piece of the Sainte Chapelle in Paris, a piece of the Arc de Triomphe in Orange, of the door of Mycenae and the Eiffel Tower, to make a library!

The creative breath is only rarely felt in the minds of our time. The proliferation of research fields and the very large number of researchers in these multiple fields is Level 2 Fascicule 18 01/23/2012

not an index of deep creation. Searches and seekers only appear in the usual C. de C.; many researchers only make fragmentary collections of results without creative power, which rarely lead to a far-reaching discovery. Others have imagination but only extending the rational C. de C., they cannot absorb the thought of the Ancients and some of their works which have come down to us.

Let us return quickly to architecture: it is presented in an absolutely meaningless language where the architect searches on his drawing board, thanks to the lines, for volumes creating impressions of "power", of "dynamism": there the architect thinks of a "parallelepiped sinking into the ground" to "break the imbalance between our sensitivity and the forms that are foreign to us"... By this phraseology, which is only an escape from the awareness of the lack of deep inspiration, one fills the head of the student of architecture with a pseudo-knowledge which will lead him only to research at the level of elucubration and will make him completely ignore his creative role.

This architectural work has been considered here as an example; what has been achieved can be found almost everywhere in other forms, other styles in other countries, other continents.

An architect can plan a lot about states and eifs on his plans. Knowing the place, with the plans, it is easy for him to foresee according to the forms and the nature of the materials the harmony of what he achieves with the living. A plan must be oriented; note that the geographical orientation may be disturbed by the environment in which the plans, the maps are installed (example: a desk, a table cluttered with various objects, natural or artificial lighting). Paper projects are bathed in the eifs of the workplace; the architect must abnegate this and check whether the transfer with the location is correct. A plan must have enough detail for the transfer to be correct. A plan can be used to rebalance a place itself, it is quite tricky to set up. Or we place a rebalancer on the plane or associate it more generally with the plane. This method only works for a certain time because despite the fact that the rebalancer does not saturate, the plane-rebalancer assembly can behave as if there were a saturation, the transfer no longer takes place from the plane to the place. (Here we become aware of this word transfer which absolutely does not mean passage from one place to another, by a path, but something which enters into the characterization of the first place and passes into the characterization of the second).

Exercise :

A copper, or brass, or iron triangle is made and placed in a horizontal plane.

- 1) Check that whatever its shape, the orthocenter H - meeting point of the heights of the triangle - is a particular point and that it emits high C. of T., their flight and even VC and FV
- 2) Check that if the triangle is made of aluminum, we no longer have these eifs.
- 3) We plant a vertical rod in H which acts as an antenna.

a) Check that we have all the eifs announced below but that we detect them in a large enough volume around the triangle.

b) A hollow metallic sphere is welded to the top of the antenna.

Check that we detect novelties: this is what we have named

Golden Light - LD

Silver Light - LA

Ember Light - LB

Crystal Light - LC

Each is called an FI. There are only 4 Ifs.

thus what we also called AVÆCUM.

“To give real existence to things  
which in the phenomena of nature  
have remained in the state of intention. »

Goethe

### *H. The Creator Word and other eif*

If we refer to Goethe's color theory, which was opposed to that of Newton, and was not recognized, it appears that Goethe insists on the so-called peach-blossom pink color. It is now called red-magenta or magenta.

If we test this color - which is not in Newton's spectrum - we find an eif that we have named Creator Verb (VC). Moreover a word in Old Sanskrit emits this eif, and this word means Creator Verb - It is also from this word that we discovered it

Shortly afterwards we found another which we named "Famous Green" (FV) to distinguish it from V,  $V^+$ ,  $V_M$ ,  $V_M^+$ ,  $V_E$ ,  $V^{\wedge}E$ .

#### Note :

If we examine carefully certain paintings representing religious scenes, we realize that the colors: green, magenta, golden yellow, red, azure blue, are often present - The painter, it seems thus, brings in these colors to bring relocation in the table. Moreover, by testing, we realize that we are not in the presence of the eifs of the EFF spectrum but of other eifs which are not the C. de T. and their flight, this is how we place VC and FV and something else which is not eifs but which we call IFS (LF. for inter-face, as if it were placed at an inter-face; this analogy will be forgotten later).

### *///. SFIs*

#### 1 ) Classification

We get 4 Ifs:

|     |               |
|-----|---------------|
| LD  | Golden Light  |
| THE | Silver Light  |
| LC  | Crystal Light |
| LB  | Ember Light   |

Now consider the Light and Darkness of the Bible, which is not dark and sunlight at all in the sense of classical physics.

Let's do (FV, Darkness; VC, Light). This has a halo. Let's call it Golden Light. We see immediately that LD is not an eif. It's as delocalized as all the eifs considered so far. If we look carefully at certain paintings depicting religious scenes, we

fairly often sees colors green, magenta, golden yellow; it is possible that the painter emphasized 3 colors to evoke the delocalized, that is to say the two eifs: VC and FV and the halo LD

We will refer to the exercises for the detections.

You have to be careful and only name other eifs if you really need them! A little-known color, used only by painters and not at all by physicists, and on which Goethe insisted a lot, is that named by him "pink-peach blossom". It is now called red-magenta or more simply magenta. It is not in Newton's spectrum, but it is found in Goethe's spectrum. If we test this color, we realize that it emits an eif which is not in any of the previous ones. It is called the Creator Verb and this because it can be detected on a word in Old Sanskrit which means Creator Verb.

## 2 ) Consequences

So we still found new eifs and ifs; this was possible and will remain so for what follows, because we kept in mind the idea that the previous set of eifs was perhaps not complete? Someone who would have wanted to restrict these eifs to the set drawn from the colors with the rigor the acceptance of E and M, would have found some of these eifs to characterize "magenta". He wouldn't have been wrong! Roughly speaking he would have described with consistency. Is this consistency sufficient; There is the question ! He will approach the rest of this research with this consistency. Let us point out here that the choice of eifs is not coherence, it is only the beginning of a coherence. It contains the state of mind of the researcher, even what he will do with it afterwards. The choice of eifs, for example, is only a matter of appreciation of the researcher-obs. Everything that is said for the eifs is true for the rest. This is also true in the rational domain, and as we live in the usual C. de C., it lends itself very well to this: it is that we identify much better the elements of the chosen sets. Let's not forget that in the usual C. de C., the choice of the set and the elements is simultaneous; it is only in the formulation in the usual C. de C. that the elements are constructed in the form of a set. The tacit knowledge or rather the research in the installation of the tacit knowledge of the C. of C. rational, is not in the C. of C. rational.

Why do we say that the choice of the set and the elements is simultaneous? Because it makes no sense to seek one before the others or vice versa as existence in relation to an origin of time. The birth of the whole and that of the first elements is not in the history of the awareness of their existence. If we want to build another story which would be the one

of their separate existences, it doesn't make sense. No more than that of their existences beginning simultaneously as we said above, but here we were only preparing the reader and we put him in a dynamic thought, which moves as it evolves, which adapts at the same time as it evolves which makes it very obs, always original. There is only instantaneity which is not a limit towards zero duration, but rather a perpetual catch-up of the birth of duration. The perpetual is in catching up with the appearance of any duration. In the rational world the perpetual is rendered by the continuous or the quantifiable with the relation of total order. So if we go back to the construction above, we now understand the concept of Enel presented in [1] The human being carries stories with him, his memory is filled with history but also his attitude and his descriptions of others, of others who are in are C. of C.. A story is a piece of coherence or a description using pieces of several coherences. A story can thus cross coherences belonging to a C. of C..

Cyrano de Bergerac [5] writes: "I was beginning to fall asleep in the shade when I saw in the air a marvelous bird hovering over my head; it was supported by a movement so light and so imperceptible that I doubted several times if it was not still a small universe balanced by its own center. He descended, however, little by little, and finally came so close to me that our relieved eyes were filled with his image. Its tail looked green, its stomach enamelled azure, its wings incarnate, and its purple head gleamed, waving, a crown of gold whose rays sprang from those eyes. He was a long time flying in the clouds, and I clung so tightly to everything he was becoming that my soul having withdrawn and as if shortened to the single operation of seeing, it hardly reached to that of hear, to make me hear that the bird spoke while singing".

We will not go further in this text, but retain the colors which allude to VC, FV and LD. There is also the evocation of an azure color; we don't have any eifs to match it. In alchemy, the two eifs VC and FV as well as LD which is no longer an eif, are necessary.

In summary, we have seen:

- The two spectra: undifferentiated and differentiated, consider the continuums. These eifs are called: EFF level eifs
- Then the Champs de Taofel and their escape.
- Then VC, FV
- Then LD, LA, LC, LB which are Ifs.

But have we exhausted everything! It seems that with everything presented above, we have a good arsenal at our disposal for everything related to forms, living systems, the rebalancing of places, dwelling houses, etc.

We have not spoken of the states, the first time evoked by de la Foÿe, nor of the atmospheres established by Ravatin. Indeed, if states and atmosphere are necessary for the study of forms, it is no longer at all eifs nor this other thing that is LD. On the other hand state and atmosphere are to be taken into account for all that relates to the forms and unfortunately many people being interested in this field or pretending to be interested in it ignore them completely. There are even some who make states of the eifs. This is the big mess in their results and interpretations.

#### Exercises :

Check that the sap emits VC

On the other hand, if it is extracted with a centrifuge, VC is no longer detected, even if a detection device is applied with the left hand: the thumb on the little finger and the three other fingers two by two side by side and directed towards the container containing the sap.

If left to stand, the sap extracted by VC centrifugation comes back but less clearly.

If we want to extract the sap and keep it VC, it is necessary to bend the plant but not to twist it.

Dew has an ext but not VC

#### Exercise :

Let's take a magenta screen and illuminate it with white light.

On the other side of the screen there is a magenta color radiation.

- 1) We then illuminate a piece of nickel by this radiation: check that we have very clearly VC
- 2) If we place a crystal in VC, we detect a channel.
- 3) It is very strong if the crystal is replaced by iodargyrite and even stronger with kasolite - These stones can be ordered from crystal merchants -

### 3 ) Remarks

We can use certain bulbs which give off magenta lighting, i.e. we detect

V. C. in the path of light rays. Multiple assemblies are possible, for example to put the bulb between the spark gaps of a device with multiple wavelengths of Georges Lakhovsky or to put it in a dynamizing pyramid. We can detect VC in the Universe. Level 2

look into what is called in astronomy: the jets of galaxies. It was in 1918 that such a phenomenon was reported (publications of the Lick Observatory in California). Astronomer HC Curtis notes that the (almost round) nebula Messier 87 has a curious straight ray, apparently connected to the core by a thin line of matter [6]. At this time, about 150 jets have been listed.

These jets are made up of high-energy particles confined in a very narrow area that shoot like water from a small pipe under high pressure. In the case of the M18, working on a photo, we see that there are several decals and "channels" in the galaxy and outside it. VC is detected in a portion of the Universe which is very large compared to the volume of the galaxy and the jet. But here you have to be careful, you only detect the VC because you are considering a very large volume. If we place ourselves at the level of the volume of the galaxy, there is no VC; we must not forget that we are in a domain that is no longer rational in the sense that we manipulate notions describing existence without landmarks. The radio jets of galaxies are not always rectilinear, such is the case of the galaxy NGC 1205 located in the center of a cluster of galaxies. VC is well detected in a large volume, as before. On the other hand, it seems that there is such a jet coming out of our galaxy; if we test, we cannot find a VC, the volume probably not being sufficient for the test to be positive.

Exercise : Put a Newton spectrum on a black background. Check that we find FV The latter is amplified by a colorless glass ball; the amplification is greater than if it is a wooden ball. If we put an iron ball, the FV disappears. If we put a piece of germanium in the F. V., we get VC.

Exercise : Consider 2 round or square transmitter plates and a mercury tank. Let's emit one of the plates in  $V^+$  and the other in  $V'$ , that is to say at the exit of  $V^+M$  we recover respectively the  $V^+$  and the  $V^*$  and immerse the two wires in the mercury tank . Then check that it comes out of the tank FV Replace the mercury with water and  $V^+$  and  $V'$  with R and  $V_j$ , it comes out of the water VC

In these two assemblies one can use only one disc with two needles, but it is necessary to arrive, for the first, in mercury, and for the second, in water to have these new eifs.

#### 4 ) Remark

We can therefore see that the composition of the eifs is very delicate, because it depends, in the previous case, on the transmitter trays, and on other forms. technical objects.

During the research a new fact appeared and this about LD and LCJ, de la Foÿe had introduced polarity in his study of forms. There are two polarities; they can be detected with pendulums on which right- or left-handed helices are traced. Forms have these two polarities, others do not, others are strange, because it is necessary to use the two pendulums (polarity D and polarity G) simultaneously to have an answer; for the latter it seems, in certain cases, that the two polarities are confused at the same point, for others it has a completely different meaning, which we do not know. Maybe we should think Dd between the polarities or one of the other concepts presented in [1].

But there are no polarities for eifs; this only applies to the forms. Something else equivalent to LD and LC has been thought to exist and this by taking the notions of the ethers from the occultists and in particular the alchemists for whom there were four ethers (see [ 1]).

1. The ether of heat with which the radiating forms in balls are associated.
2. The ether of light with which radiant forms are associated in very fine beams, for example: leaves of ferns and acacias.
3. The ether of chemistry with which forms like oak leaves are associated.
4. The ether of life with which are associated the cruciferous, pentameric and hexameric forms.

For occultists, their imprecise language means that the ethers can be confused with the aether of L. Boutard. Rudolf Steiner used these four terms in the language of occultists but this has been deep in thought and takes on great interest given the quality and depth of his research. R. Steiner had a personal coherence impregnated with occultism but a dazzling intuition which left him the possibility of using a little evolved language to arrive at astonishing results. For us there is no question of confusing these four ethers with that of L. Boutard. They have common characteristics in the sense that they can be considered as reflections according to certain interpretations of Boutard's aether. And the aether constructed by Boutard is a description following a representation (that of Boutard) of  $\mathcal{A}$  defined by our care as a halo in [1]. We therefore named Silver Light and Ember Light these novelties. Ravatin after having introduced the notion of male and female in the equivalent of the interface (by transport of structure) set up the character:

LD and LC have the masculine character

<sup>2</sup>The notion of interface will be justified after the presentation of the avæcum.

LA and LB (LA for Silver light and LB for Ember light) have the feminine character. The alchemists use this concept when they speak of the sun which is masculine and the moon feminine (which moreover respects French grammar). It should be noted that the sun has a very clear masculine character, while to detect the character of the moon one needs a form - revealer.

Let's make a solid wooden sphere and cut caps to make a cube with rounded edges and ends. Let's put this shape near or against an amethyst crystal: it comes out LC and LB. Male-female pairs are LD-LA, LC-LB. LD-LA can be in Dd, in equimsey or one overlapping the other, likewise for LC-LB. You can even combine 3 of the 4 or even all 4 together. They can also be inserted into a T AG<sup>3</sup> system. As by transport of structure starting from the idea of interface, one placed LC, LD, LA, LB; remember that they are given the name IF (IF: for Inter-Face). So we have four Ifs.

Consequence : We present a short study on Sathya Sai Baba.

A. Crani in [7] writes "it was in 1953, when he was twenty-seven, that Sathya Sai Baba addressed the crowd for the first time, thus beginning the cycle of his teachings. All of his published speeches have been translated from the original Telugu into the English language by his biographer, Professor Kasturi. They were published in ten volumes. The first volumes in French appear little by little. "The discourses of Bhagavan Sri Sathya Sai Baba are as important as the Bible and the Gospels are for Christians, the Koran for Muslims, the Vedas for Hindus, the Gathas for Parsis and the teachings of the Buddha for Buddhists" assures Crani. It is said that Sai Baba himself declared that his speech is a real spiritual nourishment which gives strength and courage to any sincere aspirant to advance on the path which will bring him to his own realization. His speeches contain advice, reproaches, small spiritual oaths in the form of admonitions. Sai Baba declares "I came to answer the prayers of the saints, the sages and the faithful ones who called me and to find the moral law (dharma)".

We can test Sai Baba. One notices first that it is in equimsey with something else; we do not know at the moment what it is. It emits high C. of T., their flight, VC, FV and yew. He in his system by equimsey and not him alone, has a very strong ext and an int. [1]. When he participates in the Abisheka ceremony and the localization of sacred ash on the

<sup>3</sup> See the rest of this booklet.

statue of Shirdi Baba during the great night of Maha-Shira-Rathri, the vase from which the ashes emerge responds to decalatre. The ash has eifs and Sai Baba's yews (from the Sai Baba system in equimsey with...). When Sai Baba locates a statue of Krishna in the sands of the Chitravati River [8], the statue has ext and int, [1]. it also has the previous eifs and ifs. The statue emerges from a decalatre.

#### iv. *Gate*

When we want to detect with pendulums and rods and when in particular we work on witnesses (plan, photography...), it can happen, this is quite rare, that the responses to the study are unexpected and even that it there is none at all. In this case we realize that we are in the presence of what is now called a grid. Grid because everything happens as if the detection was partially or completely obscured. A grid can be wanted by those who do not want a detection to be made on the forms, in the broad sense of the term, in which they are interested or have been interested; it can appear on its own.

When during a test, you come across a grid, you have to lift it. For this a ritual or forms are set up on the plan, the photograph etc. The grid may remain up after the ritual has been performed or the forms have been removed; more often it falls.

A case where a grid is found is cited in the work of V. Rosgnilk [2]: the Miracle of Lanciano. We develop it here.

Note that the grid may not exist for everyone.

Lanciano is a city in Abruzzo; around the 700s there was in the monastery of St. Legoncian, where the monks of St. Basil lived, today the convent of St. Francis, a monk who went from day to day doubting that in the consecrated Host were present the body and blood of Christ. However, he constantly prayed to God to remove from his heart this wound that afflicted his soul. While one morning, after pronouncing the words of consecration, he found himself deeper than ever in his error, he saw the Host transformed. The Host had turned blood red, it seemed to be a piece of flesh and the consecrated wine to be real blood which coagulated into five irregular clots of different shapes and sizes. The monk turned to his followers to share his amazement and his joy at the miracle It is possible that at the beginning of the blood-red coloring, the monk, taken by stupor (a state favorable to transfers) projected onto the miraculous transformation certainly, in progress, his hope and his distress and then the orientation was made towards flesh and blood. But it's only an hypothesis ! From 1574 until recent years. all the

. historical course and details of the experiments can be found in [8]. A few pages are devoted to it in [9]; this book is interesting for the multitude of miracles of this type or other strange phenomena of a religious nature listed and described.

It appeared a few centuries after the miracle, a grid, which makes it impossible to test correctly; the ritual of the mass, made in this church, raises the grid during the duration of the mass and after it falls down. Very strong eifs appear and permeate the celebrant and the faithful who follow the service. But the impregnation can last after they leave the church. Transfers, when the gate is lifted, can occur with other holy places. You have to be very careful about this.

About these grids people claim never to find any because they consider, and in this they place themselves in a position of superiority, that they are strong enough to lift, without knowing it, the grids thus getting rid of this concept. Geobiologists, on the other hand, completely ignore it.

These are attitudes that are often encountered in non-orthodox fields, where so-called researchers tend very quickly towards positions that they create for themselves, very privileged. They crown themselves.

In the case that concerns us, the negation of the grids corresponds only to a search for power which completely erases the search for subtlety which is brought about by the understanding of the necessity of the concept of the grid.

To deny this concept shows a lack of subtlety with respect to what one wants to approach.

Another concept is also necessary: that of the diving suit. Indeed it happens that after many attempts on forms, places, we find nothing and that by looking for a grid we also have no answer.

Another concept is then necessary: you have to wait and images come to mind; we see the shape, the place as if enveloped, we think of a diving suit and we test; the answer is positive. So we adopt this concept.

In reality grid, spacesuit are used by transport of structure - the concept of track seen in the preceding booklets -.

Conclusion : it is necessary, when forms, places are under grids or in diving suits, to test them, to remove these grids or these diving suits.

So for that we use shapes like constellations but also something else.

## v. TAG system

Let's look at a very particular shape before continuing: for this let's consider two identical enclosures  $G_1$  and  $G_2$  separated by a corridor  $H$ .

These two enclosures can be made by 2 pieces with a rectangular horizontal section and a trapezoidal vertical section. The roof is therefore sloping and equipped with two dormers which are in the plane of the roof. The 2 rooms  $G_1$  and  $G_2$  are symmetrical with respect to the vertical plane of symmetry  $H$ . Two doors, therefore symmetrical, allow entry through a corridor into  $G_1$  or  $G_2$ .

First assume the two rooms are empty. Due to the lighting, the location etc., we will have an atmosphere in  $G_1$  which will be the same as in  $G_2$ . The atmosphere of  $G_1$  and of  $G_2$  will be called "Atmosphere", which is much more abstract than the atmosphere of  $G_1$  and the atmosphere of  $G_2$ . For the system  $G_1, G_2, H$ , there will be an atmosphere. The Atmosphere is not a state or an atmosphere. In  $G_2$  in one place we can put a form and place ourselves in  $G_1$  at the symmetrical position occupied by the form in  $G_2$ . Thanks to the Atmosphere we can work as if we were next to the shape placed in  $G_2$  while we cannot see it. This allows to be very effective on the form. The  $G_1, G_2, H$  system will be called the TAG system (T for transfer, A for atmosphere, G for generation).

Consider the human brain. There are two hemispheres and between them the corpus callosum. We will only consider this: we are not quite faced with a TAG system. Naturally we must suppose the existence of an atmosphere in the sense in which we presented it above; this one not being localized, it could not be detected.

Let us now consider the Obs, the pendulum, and that we represent (model).

Let's put on the TAG:            1st hemisphere,            callous body,            2nd hemisphere

the system                      Obs                      Pendulum                      the model

According to the correspondence indicated by the arrows. Knowing how to use a pendulum means allowing the Obs to create a particular position between the Obs and the model (everything happens as if by pressing the Obs were placed in one hemisphere, or  $G_1$  the model in the other hemisphere, or  $G_2$  and that the positions in  $G_1$  and  $G_2$  are symmetrical with respect to a place passing through the corpus callosum).

Plating on the TAG of the system (Obs, pendulum, model) as we indicated above creates an atmosphere, and at that point the TAG is the system plated as well, resulting in

the operability of the obs on the model. Here is an overview of the dowsing process. It's a little more complicated because the model is not the reality. To go further, the notion of equimsey must again be brought into play.

Let's summarize the above: Consider two identical speakers  $G_1$ ,  $G_2$  separated by a corridor  $H$ .

These two enclosures can be made by 2 pieces with rectangular horizontal sections and trapezoidal vertical sections.

## Chapter XIV

In this chapter, many of the montages reported to produce Avoecum are left as exercises.

### *AVÆCUM*

The Avœcum was discovered in December 1986 by J. Ravatin. He had foreseen its existence - of course not in the rational sense of the term, but existence linked to the global - for several years.

The Avoecum behaves differently from all of the above.

We can check that a Sprink-type device - we talked about this work in a previous booklet - does not emit Avoecum.

Georges Lakovsky's ultiple wavelength oscillator - which we will see later - does not emit an avoecum

On the other hand the assemblies of JW Keely, the orgone guns of W. Reich, the apparatuses of Louis Boutard emit Avæcum.

It was necessary first of all to find a form to emit avæcum. J. Ravatin imagined, to produce the avæcum, what he called an avæcum cannon. This is made up of a wooden parallelepiped with a cavity containing different bodies and in which a wooden prism slides. The square section prism has a greater effect than a cylinder. The prism is full.

Under specific conditions, this cannon emits avæcum. It should be noted that the detection is done in the rectilinear extension of the wooden prism, it starts at approximately 20 cm but this distance can vary according to the importance of the barrel. Moreover there is no dispersion. It looks a bit like a laser beam. Note that we often had this with the eifs but dispersion could appear at the ends of the needles of the transmitter plates if they were not very sharp. Here in addition, what is completely new is the "range" of the gun, which is measured in tens of thousands of kilometers.

The eifs would be to the avæcum what the foam is to the waves. What is written (eifs, avæcum; foam, waves) and this has a halo that for the moment we do not know.

The avæcum is a unit; there aren't many like eifs. On the other hand it seems that it has two components which are not of the avæcum, this is why we say that the avæcum is a unit. These, pictorially, can be described as follows: a mass component, dark gray containing the other component formed of orange-red colored sinusoids, deforming very slowly and moving in translation <sup>4</sup>. It is a possible representation. There is no noxious state in general which is attached to the avæcum or its components.

<sup>4</sup>The advantage of such an image makes it possible to formulate in depth the entity Avæcum. Such approaches are very common in this field. They resemble dreams which themselves are extraordinarily rich. It is the intention that intervenes in this case. Let us quote information provided by René Clair and on Hugues Pamassié, specialist in Jazz, and who had achieved constant clairvoyance by drawing all reflection to him for the benefit of the imagination. He said, among other things, that one does not dream because one sleeps, but that one sleeps carried along by the dream which is established in view of the rest due to sleep. Hugues Pamassié died on December 8, 1974.

Thus, let us stop at this thought of H. Pamassien We do not have a permutation between sleep and dream:

Usual point of view: We dream because we sleep, which we will summarize as follows: sleep => dream

Point of view of H. Pamassié: we sleep carried along by the dream which is established, but in view of the rest due to sleep, which we interpret as follows after having posed:

Ext (awakening) = dream in the sense of a dream

and (sleep) <sup>(dream)</sup> = rest

Thus is expressed the point of view of Pamassié.

We can also take the rational point of view by completing it as follows:

.../...

With the avæcum, one can engender all the eifs. From the eifs one can also pass to the Avæcum, for example if one sends VC on the star of David, one obtains the avæcum.

You can load metals in avæcum, you just have to place them at the exit of the barrel. If they are heated they lose this avæcum; there are, however, exceptions: for example, lead, gold, platinum keep the avæcum on fusion, and even this becomes stronger.

Chromium oxide (O3Q2) in pieces (it's hard to get that way, because it's always sold ground into a fine powder) and chromite (which is a mixture of chromium oxide and impurities) emit 'one and the other of the avæcum and very far reaching. But let us specify well, it is necessary that the chromium oxide, if it is about him that it is about is, in pieces. If the powder is agglomerated, this does not happen. Mixtures of chemicals can emit avæcum; there is a direct use for unorthodox research, of constituents of the usual C. of C..

To “amplify” the avæcum one can put chromium oxide in a spherical cavity. It has to be in pieces.

You can also amplify with solutions of nickel chloride or cobalt chloride that you put on the beam. There is no deviation. We take a cylindrical glass container.

Crystallizer  
Water + Cl<sub>2</sub> Ni  
Or Cl<sub>2</sub> Co

One can also amplify by sending the beam on old light bulbs, on empty or full bottles.

There are forms which are like reservoirs of avæcum - we will say "reservoir" when we can make the system an emitter of avæcum -. Let's look at some examples: first let's consider

---

sleep, U, rest, => dream,,

We cannot bring in the concept of overlapping, this concept has no meaning in the usual C. de C..

moving clouds on the sky considered as a background. The whole constitutes a reservoir of avæcum. One can, with an appropriate supplementary form, draw from the avæcum of these moving clouds. If we don't have the concept of form over substance, what do we detect? We will not detect a "reservoir" of avæcum! If we have the concept of avæcum and someone places a form that triggers the presence of avæcum in delocalized mode, we can detect this avæcum. If moreover one does not have the concept of avæcum, one can very well not detect anything at all. It happens that when you don't have a concept, you don't detect anything, or that the test suggests the concept.

It can also be found in a somewhat similar case thanks to the movement. Consider for this a locomotive that pushes wagons up a ramp in preparation for the shunting of a train. The cars separate on the descending ramp and then take different tracks thanks to switches. Let's consider the whole of this train, let's say "split", made up of all these single wagons moving on different tracks. This "exploded" train moving in the marshalling yard (if it is alone) is a reservoir of avæcum.

The starry sky (without clouds) during a night is in motion. It is the sphere of the fixed ones. If we put on the ground, suitably arranged, the five hollow Platonic solids, made of iron or copper, of approximately the same size, we have a reservoir of avæcum. If there are clouds in the sky, at night, without a moon, it is still a reservoir of avæcum. The five Platonic solids delimit an area whose interior is particular.

Three crystals: a purple, a yellow, a green and not just any; for example: purple opal, natural citrine, machite; which, moreover, all three are in contact constitute a reservoir of avæcum.

Consider a dynamizing pyramid: it has a square base, it must be associated with a number which is neither the golden number nor the radiant number. We have a channel in a region near the center of the height of the pyramid. Let us place in this region the three crystals in close contact, it comes out of the avæcum, from the C. of T., and also VC, FV, and LC.

Let's take the three crystals, still in contact and subject them to an electric field, it no longer comes out of avæcum but VC, FV, LD and LC. If we place the three crystals, only in contact, at the top of the head, we load in VC, FV, LD and LC. The human body transforms the avæcum into these eifs and others and also into C. de T. and their escape. A stone that has a CP, placed on a piece of wood is a reservoir of avæcum.

Menhirs surrounded on two sides by half-trunks of dug, vertical trees, are reservoirs of avæcum. It should not be inferred that the menhirs were caught between two such pieces of wood.

If you take pieces of obsidian and put them in powdered chromium oxide, it emits avæcum.

Consider a TAG system [1] and [2]. Let  $G_1$  and  $G_2$  be its speakers symmetrical with respect to a central corridor. Let us put in a point of  $G_1$  a piece of chromium oxide and in symmetrical position compared to the plane of symmetry of the system, of water; water takes on avæcum.

We have seen that a solution of chloride of nickel greatly amplifies the avæcum. It is the same for bromine water, or water colored by iodine.

Just as closed glass bottles placed on a bundle of avæcum strengthen it, so an amphora greatly strengthens it.

Crystals charged with avæcum, pressed or heated without there being destruction of the crystalline mass emit even stronger.

If you aim an avæcum cannon at the decalar of a Sprink device, the decalar disappears; it is replaced by a channel which can be detected in the entire extension of the barrel.

If we send a beam of avæcum on a decalar, the decalar disappears, but all along the beam of avæcum we detect a channel. Naturally when one evokes a decalar, one implicitly supposes that there is flight of the reference marks; the avæcum is delocalized but the beam is identifiable, the beam can be sent in a direction in which the escape of the landmarks occurs. It is interesting to remember that the local is a support for the delocalized.

We will also see in the study of the planes, and more generally of the surfaces attached to cathedrals and certain large buildings that by using a structure of projective geometry made for the points by hollow spheres, connected to each other in an adequate manner, we create high C. of T. eifs and their flight, VC, FV, LD and LC, but also of the avæcum. This structure constitutes an aether pump. Let us have shifts in certain regions of space, in number given by the order of the projective geometry chosen (this order is an integer and the number of points or lines of the geometry is given by the formula  $k + k + 1$ . We note that the case  $k = 1$  gives nothing of interest in the domain where we are), there appear paths between these shifts which are of the “channel” type. There are as many “channels” as decalars, since points and lines in a projective geometry are of equal number.

One can find other simple and compound bodies which, when placed at a certain distance from each other, will produce potent avæcum, but there is something more. We don't know what it is yet!

Jacques Ravatin noticed that at the time of the solstices - a night close to the solstices - the earth is bathed in a kind of eif "rain" which is VC. It's not continuous. They are detected approximately every 30 seconds to 1 minute. It is stronger at the summer solstice. On the night of June 24-25, 1987, it started at about ten past midnight until 4:00 a.m. The period is not constant; we had stops of 20 to 25 seconds per moment and we detected very strong VC for 45 to 55 seconds, this around 1 am. The avæcum emitted by a gun turned into a C. de T. leak during the detection of VC. There was even alternately high C. de T. and their escape; immediately after 4 o'clock in the morning the avæcum was found.

Note that the Ark of the Covenant emitted the avæcum and likewise the Great Candlestick with 7 seven branches when it was lit in a certain way. In the case of the Ark of the Covenant, the two kerubim sent the beam vertically. Two winged goats face to face emit avæcum, likewise two winged bulls. If we put two winged human representations face to face, it's much stronger.

The amplification of the avæcum can be made at the exit of a gun having perpendicular to the ground and to the beam 10 double mirrors. The distances between the mirrors vary with the orientation of the avæcum beam and the place where the experiment is carried out. You have to choose the distances between them carefully. You can also put two hollow concentric spheres on the beam, it amplifies.

It can also be amplified by attaching a metal ring to the cork inserted into an empty bottle. The plane of the ring must be vertical and it must be broken at its highest part. If the bottle is potbellied, it's even better. You can make batteries of bottles and rings but if you don't want the beam to be extinguished or deviated, you have to connect the bottles together.

It is possible to reflect a beam of avæcum. One or two mirrors do not have this effect; it

three are needed with very precise angles between them. A swastika of shape , drawn horizontally in the ground and crossed in its center by a vertical rod emits from the avæcum. This is not the case for the symmetrical swastika of this one with respect to a straight line.

One can bend a bundle of avæcum. It is necessary to plant in the ground pieces of wood with square section according to the diagram which one will find further.

You can put two identical guns face to face. No more avæcum comes out but at the center of symmetry of the assembly, perpendicular to the axis of symmetry, we detect high C. of T. If we place 3 identical guns directed along the axes of symmetry of an equilateral triangle, and corresponding by rotation of  $120^\circ$ , nothing is detected, it is an absorbing form. If now we consider 4 identical guns which correspond by rotation of  $90^\circ$ , we detect something but it is not in the close vicinity of the shape.

It is not detectable in a region of space. The AND structure can no longer be used to determine an action zone. We are not facing an avæcum or EF reservoir. It is quite another thing. Until now we had more or less delocalized but the effects could manifest themselves in regions of space. There we can no longer rely on near or distant neighborhoods or even distant regions. The study is very complicated. Suppose now that we have a form that sends avæcum in all directions. If you want to channel it, just press a solid wooden prism or a solid wooden cylinder against the form; the avæcum is detected in the extension and is no longer detected elsewhere. Avoid putting an avæcum cannon in a house. The avæcum can be enlarged or it can turn into multiple eifs and in some cases this can be harmful.

The avæcum carrying very far, one can send some on a mountain for example. If the mountain range contains ice, and it is sent on it, the avæcum is amplified, but the amplification is felt even close to the emitting cannon (if it is sent by a cannon, this is often used because the beam is easy to direct). If the beam is sent to a mountain massif supporting a lot of vegetation, the avæcum is transformed on the massif into LD, LC, VC, .FV. If we send avæcum to a forest, we detect, as in the latter case, LD, LC, VC, .FV or some of them <sup>5</sup>.

Some words pronounced several times make the one who pronounces them send avæcum. These words do not always belong to a humanly known language. They have to be made. We can

<sup>5</sup> If one sends VC on mother-of-pearl, one obtains avæcum, whatever the form realized in mother-of-pearl. If we send FV on mother-of-pearl, we get ifs.

direct a beam of avæcum on the sun: it is amplified if a yellow filter is placed on the path of the beam; if this filter is magenta, it is even stronger.

cannon

Here we do not detect anything

Deflection of a beam:

Three vertical wooden prisms  
Their positions are very precise Prsimes are square sections.  
A diagonal is parallel to the axis of the barrel.

If we consider the following assembly: 2 barrels whose axes are in a horizontal plane and perpendicular. Let us put the zone of intersection of the two beams in a hollow tube placed on the ground like the guns and such that two faces are respectively perpendicular to each beam. We amplify but on each outgoing beam we detect a channel.

It can be seen that the amplification methods are multiple; only a few have been cited. You can find many more. As for the eifs you have to be careful if you want to amplify not to transform.

Religious buildings: churches, cathedrals, synagogues, multiple temples do not emit avæcum. But we can make them emit it not by the usual rituals, but by manipulation of what we will present in other studies which will be the planes, surfaces, volumes linked to forms. These planes, surfaces, volumes are not the forms usually seen, completely localized or even partially delocalized.

Let us give some complements on witnesses of being alive or dead. Let us put in a flask, in colorless glass, filled with water, a piece of bone, then we stop the flask which we put in a bundle of avæcum. There is a strong amplification of the avæcum. If in the water we send a few

drops of nickel chloride, the amplification is even greater. Let's take the bottle that we fill with water sprinkled with clay: let's put a piece of flesh from a living being, the avæcum is amplified even if there is no clay. Always with the same bottle in which we put pieces of clay with a photo of a living being; there is amplification of the avæcum as soon as the stoppered vial is placed in the bundle. If the living being is dead, the avæcum is partly absorbed. If the being is alive, the FFV is detected in the beam. If the being is dead, and we put the letter aleph in the beam (written in biblical Hebrew), we detect the FFV.

Steel balls can, in certain assemblies, create avæcum. 8 balls arranged at the tops of a regular octagon and one in the center.

Ball diameter: 26 mm to 30 mm.

Radius of the circle circumscribing the octagon: 1

The box is made of tinplate (the inside must be reflective like tinplate but not colored).

Inside the balls are made of steel.

On the tin box (idem previously), a mirror whose reflecting part is towards the outside of the box)

steel balls

The avæcum is stronger.

The assembly opposite is immersed in a crystallizer containing water.

The avæcum is stronger and can be detected very

The avæcum is detected closer to the barrel than when there is no mirror. Nothing is detected in the part of the exterior plane at the angle  $xOy = 43^\circ$ . If we take an angle such as  $xOy$  but with a value other than  $43^\circ$ , the beam passes through with an amplification effect.

Case of a reflection of a beam. You need three mirrors. If the angle of incidence between the  $zz'$  axis and the  $xO$  plane increases, the angle between the  $z'z''$  axis and the  $O'y$  plane decreases. It generally takes 3 mirrors to obtain the reflection of the beam. It can be seen in the figure that the shape formed for these three mirrors is important. Reflection with a single mirror is possible; it follows Descartes' laws for geometric optics, but something else must be inserted into the editing.

Avæcum can be obtained from VC by sending with a Lakhovsky oscillating circuit the VC. You have to respect the editing as described by G. Lakhovsky.

CV

The angle of the plane of the circle with the ground must be approximately  $23^\circ$ ; if the angle is smaller or larger by 4 to  $5^\circ$ , the avæcum is no longer detected at all. If, instead of VC, we send FV, we get ifs. If liquid crystals are sprinkled with avæcum, they emit very strong avæcum, long after leaving the beam.

One can find in a plan 28 points, which, when they are well pointed or pierced, emit a very powerful avæcum. This arrangement can be made in a field by making holes with a stick. The avæcum is also very powerful. But with this system of 28 points or 28 holes, we have something else. If we remove or add a point or a hole, it gives nothing. We can plant 28 sticks surmounted by hollow spheres, we still have the previous properties. One can pierce a wooden plank and light it with an ordinary electric lamp, the avæcum is very strong. If we illuminate with a lamp that sends VC or FV, we get ifs. The plate put in the dark, there is no avæcum. In the moonlight, the avæcum is very strong.

## Chapter XIV (continued)

### 1. *The Acaecum*

The forms and combinations of forms possible to obtain avæcum are multiple; we will quote them later. But we are going to stop on a rather extraordinary form which, it, makes it possible to generate avæcum but much more. This form is linked to the life of Jules Verne. It is named: Jules Verne Pentacle, Jules Verne Grid or Jules Verne Medal.

The words grid and medal were not chosen at random. There is a very deep reality behind all this.

Nonsense has been told about this form, as well as stories that are not easy to verify, such as this: Jules Verne would have had it engraved on the back of the armchair in which he spent his days and nights writing his novels. .

We were able to verify the effectiveness of this pentacle (such is the denomination that we will use). The properties of this pentacle change with the place, the hours of the day and the night, the position of the sun and the moon. Under certain conditions these properties remain regardless of the conditions indicated just above. It can be made of paper, metal or even plexi-glass <sup>1</sup>. What is very interesting with this form made of this material is that it can be used with moonlight and then it behaves like a moondial. Two needles must be used for this; it is preferable that their forms be special. The apparatus thus produced, can according to very precise orientations in space and at certain hours of the night, according to the position of the moon during the year, put in transfer with what will be called thereafter the Firthes (or Intelligent Forces obtained by arrangements between Arkhams and Mahkras).

<sup>1</sup> It is possible that reflections and refractions of light rays would have interesting effects. Such is the case whether they are solar or lunar rays! Note also that the pentacle of Jules Verne is linked to the work of Louis Boutard. For example, each hole can be associated with a manipulation order number or even use this shape as a support in an assembly.

## *I. Supplement related to Jules Verne*

It is told in [1] that a group of seven people formed in the 19th<sup>century</sup> to bring a message to humanity.

First there was a certain Houdlum dit Nollu or Dad. We never knew who he really was. It seems that he was a seer, dowser, magnetizer, healer, hermit, Hercules.

Then Jules Vemes.

Then Thomas Alva Edison: leukemic, condemned, living within a poor family of Ohio as it is told in [1]. He was saved by Dad.

Then Jossel dit Joss: become an orphan, saved by Dad from a shipwreck in a Canadian lake; he became Dad's adopted son. He was passionate about anatomy and cosmography.

Then Jack London: unhappy in his early youth, he followed Dad's advice and became a student at the University. It is said in [1] that it was to test the recipe for strength of health taught by Dad, that J. London traveled the world and became the journalist of the so-called "Great North" team, a team made up of seven people whose we give the names; J. London was considered a writer of the "Great Test" which has again been called the "secret key" of Jules Verne.

Then Commander Sturd: an Irishman who, it seems, witnessed a rather extraordinary phenomenon. He was with Dad in the far north and there was an aurora borealis. Simultaneously, a purple coloration appeared on Dad's X-shaped chest. This coloration was slightly changing. If we test this phenomenon, we realize that when we go through magenta, it has an effect on the brain of the person on whom the phenomenon occurs.

Then Roald Amundsen (he went to the South Pole) who, it seems, met Dad for the first time in Nome on September 6, 1906, so a year after Jules Verne's death.

Then Doctor Clodel, then Tyrnu providentially saved by Dad during a railway accident . Tyrnu had a son who remained, out of gratitude and on the advice of his father, a devoted servant of Dad.

Then Alfred Renoux who was considered the eighth member of the team known as "Equipe du Grand Nord" or "Those of the Great Test".

The seven are:

- Jules Verne

- daddy
- Jossel
- jack london
- Sturdy
- Roald Amundsen
- Thomas Edison

Sturd, Jossel are perhaps pseudonyms? And the others may have been placed there to set up a whole different story. In this we must not forget that they sailed a lot, so the water is important; the same applies to magnetic and gravitational fields.

It seems that it was Dad who contacted Jules Vernes; the others gradually followed. In none of their works or biographies (of Jules Verne and Jack London) is there any question of this mysterious group of seven. Chotard has tried to find coded messages in the works of Jules Verne and Jack London. But afterwards he made a manipulation on the numbers attached to dates, places, which is absolutely extravagant; he fell into the tendency taken by many occultists who make numbers say anything. Regarding numbers, three cases may arise.

- or we make them say anything!
- or they correspond in certain cases to very precise facts
- or they serve as an inspiration to whoever uses them for any other field. Numbers would be the equivalent of a flat geometric structure where sequences of straight and curved segments can give operativity to manipulations on shapes. For example, some of these broken lines make it possible to lift grids when they have been drawn in a plan. It is enough even to have them present in mind. Thus the numbers would be the arithmetic equivalent of this geometric scheme. To the multiplicity of shapes, positions, lines, we can associate the multiplicity of properties of numbers. Whereas it is necessary to trace the curves, the numbers, according to their recursive law of generation, contain all their properties; it suffices only to extricate them from them. Numbers are a unit that we break to draw wealth from them. Curves are a construction, element by element. It is very important to be aware of the approach: the approach is the Way of the Tao doctrine. When one places oneself in the other C. of C., it is the Way which is

fundamental ; everything is built on the Way; the Way supports the story. There is no longer a goal, it is a story in which we immerse ourselves. We can be in Dd with this story, or in Equimsey.

One can also associate arithmetic approach and geometric approach. Moreover Chotard presents broken lines connecting holes of the pentacle and to these holes correspond numbers (what he calls the “Medal with figures”). This is a very special case of what we were talking about above and which he did not explain in depth, because he focused on considerations of the "simplistic esotericism" type. We give here a single plot obtained by Renoux and Chotard and taken from the pentacle.

From 1965 to 1967 came out four works by Chotard [1], the first titled as we have seen: "Tel que c'tait planned" (edited on 28-4-1961).

Others :

- "Jules Verne's Great Secret Test" (edited 14-12-1962)
- "Jules Verne divine magician" (edited 4-9-1964)
- "From Jules Verne to Extraterrestrials" (edited 20-12-1967)

The first book (in the order of publication) reproduced in full a manuscript given by Renoux to Chotard. It has been said that Renoux said "It's all in this book".

The other works are only fragments of commented texts. Chotard did not follow the instructions of Renoux who had given him the title of the second book "As it was planned" with the subtitle: "Sparks of death, Sparks of love". Chotard ended his publications by publishing under his own name a 32-page brochure: "How does Jules Verne trace in space and time the destiny of man with "Appolo" 8 and the "Soyuz" 4 and 5? (1968-1969). This booklet still contains interesting fragments of Renoux's letters.

In this booklet the point of view used by Chotard is a bit simplistic. He makes use, without knowing it, of certain events which he links together by the pentacle of Jules Verne; his system looks a bit like the manipulation of a crystal ball but it is much less rich. In the first three published books, there was this pentacle referred to as the "Cypher Medal" with a fairly brief study of figures and numbers. In addition there was a study on a figure named V (because that was its shape on the pentacle) from the first 5 cycles (the other 3 were jealously guarded by Renoux) and a curious map of Alaska on which are divided into various locations of crosses and circles.

We can work on this map; we realize that it is not too eccentric although it does not have exactly the shape of Alaska. If we plant pins vertically in the places where there are crosses and make holes in the places where there are circles and place the pentacle above this card, a very powerful avæcum comes out; we are on the other hand in transfer with these places identified by crosses and circles. Chotard claimed that this pentacle, suitably encrypted, "contained all the natural laws encrypted in a certain way"? This doesn't mean much. It remains that pentacle acts strongly on the psyche of the one who uses it.

A. Renoux had previously published two booklets

- The Great State of Balance (edited 1-3-1938)
- Lesquels s'amusement (published in 1957) and his book
- "Around the World on a Champion of the Seas.

<sup>2</sup> We were able to get this information from R. Rouaud who went to visit Renoux several times in Nantes. He gave R. Rouaud advice such as "Measure with a millimeter ruler the negative of the cover of the booklet entitled: "Le Grand Etat d'Equilibre", which he also wrote in the GEd'E, which says "I helped". Measure on the picture the base of the trapeze (the picture showed a trapeze artist sitting on his trapeze), the length of the ropes, the top of the trapeze and all possible details. Take the diagonals and see where they intersect. Measure the height of the letters of .../...

To make known to the public the first brochure that only we could have in our hands, we refer the reader to the magazine ARK'ALL Communications. We will not dwell more on this subject, this would take us too far.

If we pay enough attention to the works of Chotard, and in this area we must be very careful to properly separate "the wheat from the chaff" (We can also spend a lot of time there!), we realize that four colors intervene: blue, purple, green, yellow. If we draw a rectangle and put vertical bands colored in these four colors (like a flag), we detect avæcum. It is not in transfer with Jules Verne's pentacle, but if you place it on it, you detect a very powerful avæcum.

title, their spacing. Count the number of letters, the number of syllables; for example: The Grand State of Balance, ie 7 syllables and 21 letters.

## Pentacle by Jules Verne

The black parts correspond to holes

Let's go back to the curves drawn in a plane for multiple uses. These are most often forms that depend on the moment. They are linked to the Obs. By looking over them or rethinking them in the brain if they have not been printed on a plan, the Obs creates eifs in itself or even everything that has been described. They can intervene at several levels of equivalence <sup>3</sup>. It should be noted that this concept of equivalence levels may vary during the life of the Obs, i.e.

to say that as he invests in new concepts, the importance of the levels of equivalence changes. Other concepts become more fundamental. This stems from the fact

<sup>3</sup> See <sup>1st</sup> level course (9 booklets).

that the Obs modifies a neighborhood in the coherence radius (R. of C.) or the coherence field (C. of C.) that it launches. This modification can extend to everything that is in the field of coherence, so researchers in the same field who follow it will find themselves in the state that the Obs has put in place thanks to the local modification of the R. of C.. In the R. of C. the modification is transmitted by the Voiloc of the Obs or localization paths attached to systems which are in the R. of C. launched by the Obs.

Such tracings, if one runs through them with the eyes, give high C. of T., their escape... and even the avæcum. They also act at the cerebral level and that is the most important thing. You don't have to do just any trip. One can also use the holes which are on the sides of the square which constitutes the pentacle. But this pentacle makes it possible to obtain much more than all that. One can by routes in very precise places to have access to the Firthes (notion which one will see thereafter), to direct ideas. Now let's look at a totally different story that has been told many times in the UFO literature. This is what happened to Bamey and Betty Hill on September 19, 1961. We won't describe the event; it can be found in many books. Let's say that under hypnosis (the two protagonists no longer remembering the event) Betty Hill said that she and her husband entered 1'0. VNI, little beings had shown them a thin, flat map on a screen that gave the impression of depth; its dimension was 1 meter by 60 centimeters and one could see there many stars among which Betty retained only the most visible, those which were connected by lines. She also remembers a small triangle on the left side of the screen. In a UFO phenomenon, one should not at all describe a story as in the usual C. de C.. We have seen <sup>4</sup> that it is the trace in our rational C. de C. of an island of incoherence. This trace can also be presented as a macron. It may be that nothing happened inside the car or in the UFO, and that regression under hypnosis is part of the phenomenon. The unconsciousness of which they have the sensation in memory may be only an effect of the island of incoherence. Let's come to the map of a starry sky seen on the screen. We can say that she was able to draw very little compared to what she is supposed to have seen. But in the phenomenon there is also this impossibility of reproducing everything and in what she has reproduced there is enough to suggest a form with properties that have nothing to do with a starry sky.

<sup>4</sup> See 1<sup>st</sup> level course.

### Map of Betty Hill

If we make this shape in a wooden or metal plate and the black dots are drilled respecting the diameters of the holes, we realize that it is an avæcum emitter and at the same time a shape linked to the Æ. We are much closer to a shape like Jules Verne's pentacle than to a starry sky. We thus see that in certain cases of the UFO phenomenon, paths are suggested as in dreams.

### *IL Complements about the avæcum*

The domain is so vast that we find ourselves obliged to speak again of the forms which emit the avæcum, of the forms which are its reservoirs.

The avæcum strangely resembles the "formative forces" of Rudolf Steiner. It is not quite that because Steiner's thought was not expressed in the C. of C. which was proper to him, ie the other C. of C.. In order to be able to express the formative forces correctly he must naturally consider the avæcum but also fields of trajectories then what we have named the Firthes and much more.

Note that the foam of the waves has a fractal structure. And by taking up the approach that made it possible to create the word avæcum (before foam), we can place LD and LC then after LA and LB as at the "interface" between the avæcum and the eifs. The eifs would therefore correspond to the fractal structure of the foam.

### Exercise :

Let us point out a form which allows to have a fairly powerful avæcum: We consider a square ABCD in which we draw 2 inscribed equilateral triangles, namely IKL and MJN. This is used to plot the non-regular hexagon MJNKIL.

So, if we cut a square piece of wood such as

ABCD and only the non-regular starred hexagon MJNKIL is traced, then this square is placed on slice BC, vertical, avæcum is detected on both sides of the plate; the axis of the beam is the axis of the system, which is horizontal. The section of the beam is smaller than the area of the square.

The non-regular star hexagon resembles the shape that gives the FFV dynamism.

#### Exercise :

If we send a beam of avæcum on a capacitor with parallel blades in the following way, that is to say that the angle between the plane of the blades and the beam is zero.

Depending on the spacing  $A/$  between the slats, different eifs are obtained.

#### Exercise :

Consider two enclosures containing crystals and linked by an underground channel. The crystal may well be uncut. By this process one has a strong bundle of avæcum which behaves as if it came out of the conduit indicated by A on the diagram.

A\_r

crystal

/!\* crystal

*iiiiiii iimTmyjjimiiiiijj^/rniiiiii mm*

Exercise :

We can charge certain liquids with avæcum by a simple process: it suffices to put the liquid in a colorless glass container and to close this container with a glass whose tain is towards the outside. Leaving this assembly outside, because the liquid is charged especially in sunlight, does not discharge at night whether there is the moon or not, we see that the liquid and its surroundings are impregnated with avæcum.

//////// If this liquid is not harmful to living beings and if it is swallowed in small

quantities by this living being, the latter after absorption often emits the fields C. of T. and their escape as well as VC, LD, FV and LC.

Exercise :

We report this assembly because we can see that in the field presented here, we must always be careful: let us therefore consider a liquid that can be charged in avæcum by this process. Let's make the following two assemblies: two colorless glass containers of the same height, of different sections and both covered with a mirror.

*m mu mu a*

Let's put the same liquid in each one at the same height. We will observe that the one on the right will quickly load in avæcum while the one on the left does not load. The fluid level should be raised. There is a relationship, depending on the liquid, surface-height. There may be variations in this report according to the place and even better the moment.

“Let us learn to dream, gentlemen,  
and  
maybe then we will see the truth”

Auguste Kekulé von Stradonitz

1829-1896, born in Darmstadt, German chemist, pupil of Liebig, Dumas and Gerhardt. In 1858 he stated the principle of the tetravalence of carbon, also noting its property of forming chains of carbon atoms. He postulated the existence of a group of atoms present in certain aromatic compounds such as benzene (a group that has since been called the benzene nucleus), the structure of which he attempted to explain by a hexagonal structural formula (known as Kekule). These ideas were applied to other aromatic nuclei by Erlenmeyer and Graebe. Kékulé's work has enabled chemists to understand the meaning of formulas developed in organic chemistry; they are the basis of the sudden development of the synthetic organic industry in the world, and especially in Germany (industrial synthesis of alizarin in 1868).

Exercise :

There is a curve which makes it possible to have avæcum: for that let us consider an equilateral triangle ABC, G its center of gravity and has the radius of the circle circumscribed with this triangle.

Let M be a point of the plane, we consider the scalar field  $f(M) = \frac{1}{MA} + \frac{1}{MB} + \frac{1}{MC}$ <sup>5</sup>. Let D be the foot of the height

1V1A. IvIJD IvIV-z

$$f(M) = f(\overline{DM}) = f(h) = \frac{1}{\left|3\frac{a}{2} - h\right|} + \frac{2}{\sqrt{h^2 + \frac{3a^2}{4}}}.$$

<sup>5</sup> MA, MB, MC are the distances from M to A, B, C respectively.

The curve  $f(h)$  plotted as a function of  $h$  has a maximum and a minimum. Let  $h = a$  the abscissa of the maximum. For  $f(M) > f(a)$  the corresponding curves are formed by three loops each containing the vertices of the triangle. For  $f(G) < f(M) < f(a)$  we provide ovals, one surrounding  $G$  and the other outside. For  $f(M)$ , a single exterior oval whose shape tends towards that of a circle. Some of these ovals may have double points but only located on the axes of symmetry.

To detect the avæcum, the sides of the equilateral triangle must not be drawn. It is necessary to point 2 vertices, to pierce the third and to point the center of gravity. There is no need to impose the  $N_F S_F$ . If we draw several curves, even if they belong to different types (we saw that there were 3 types) we amplify the avæcum.

If we draw two families of curves, one connected to the equilateral triangle  $ABC$  and the other to another equilateral triangle in the same plane, fairly close to each other, we no longer detect an avæcum even when drilling other peaks <sup>6</sup>.

Let's go back to the four yews. It has been reported that they can be placed in pairs LD-LA and LC-LB male-female. One can by an appropriate choice of forms place 3 of them on the points  $A, B, C$  or even a couple in  $A$  or  $B$  or  $C$  and the two other yews respectively on each of the two other vertices of the equilateral triangle. This gives amazing possibilities. Transformations of this type are envisaged in Tantrism (the real thing and not what is presented in the West in multiple works where translators and writers have been content to compile texts and works too hastily most of the time without understanding their meaning. It is possible, moreover, that the original works contain only a superficial study, which for those who would use them, would make that they would find there only reminders). One will therefore not find in the original works descriptions attached to an obvious coherence.

The fact of making a hole in a vertex of the equilateral triangle, for example in  $A$ , imposes the  $N_F$ . Thus the  $N_F$  is on the half-line  $DA$  and the  $S_F$  on the half-line  $AD$ . You can draw contour lines on a circular or square wooden plate; the center of symmetry  $G$  of the figure being coincident with that of the circle or the square. The latter will not be pierced, simply pierce the hole in  $A$  on

<sup>6</sup> We have the polarity + outside the largest level line and - inside even if it contains others.

vertices of the equilateral triangle; it must cross the plate. We simply point to the center of the figure, ie G. We will use an articulated needle of length 4AG fixed at A with an articulation at P, such that AP = AG and with an end Q such that PQ = 3 AG. The needle will be used to locate an eif at the EFF level, differentiated spectrum. G, P, Q must always be aligned.

The contours of this field are very important. They each correspond to a value of the field. The constant values of other fields, in astronomy or fields associated with the shapes of the leaves of plants had already been noticed, respectively by Ravatin and La Foÿe. We can also use this scalar field in another way: we therefore start from an equilateral triangle ABC, we do not pierce any vertex and we draw the level lines of the field

$f(M) = rrr + \dots + 7777$ . It turns out that these level lines are "revealers". Naturally

they all exist in potency by the formula but a few plotted reveal. They are "revealers" <sup>7</sup> for Obs, in particular they reveal the possibility that human beings who are in the C. of C. of Obs can be considered as equivalent to Obs, then, that these beings humans can also use contour lines as telltales. A certain level line that surrounds others already in place, makes it possible to produce the spread of multiplicity, that is to say the possibility that the Obs has of placing the others in its C. de C. human beings equivalent to him and all living beings outside of him; and to assume this property true for all living beings.

We could have found other fields. Besides, the field  $f(M) = TVT' + 7777$  is studied plus 1V1A IvJzS simple as the one we have just presented. The fields of interest are those of the form

$$f(M) = \sum_{i=1}^n \frac{1}{MA_i} \quad \text{where the } A_j \text{ are the vertices of a regular convex polygon.}$$

<sup>7</sup> "Revelator": concept which will be seen later.

Their general study is very complicated and especially the drawing of the level lines. They send an avæcum above the plane which is very powerful. We can plot the orthogonal trajectories of these curves. They also have interesting properties in the field we are developing. The fields given by the same formula but for which the points  $A_i$  are not arranged at the vertices of regular polygons are less interesting. The field  $f(M) = \sum_{i=1}^n r_i^2$  whose level lines are the Cassiri ovals with the Bernoulli lemniscate as a particular curve, which corresponds to the flight of landmarks in the case of decalars or cumulo-decalars, is also less interesting. On the other hand, in the case of certain constellations, a field of the form

not

$f(M) = \sum_{i=1}^n M A_i$ , where the  $A_i$  correspond to each star of the constellation, is very interesting. He

must draw the constellation in a plan respecting the best proportions. For this we can use a constellation atlas like [2] (in this particular case if we want to use several constellations simultaneously, we must be careful that they are not all on the same scale and that we must bring them to a common scale). One must use the constellations of the ancients; these are the ones that have properties. You can also use fields that are linked to points in space, but in this case if you limit yourself, for example, to polyhedrons and especially to Platonic solids, drawing level lines is very complicated. You need computers; on the other hand the avæcum is extremely powerful. In the particular case where the points  $A_i$  are in a plane, it is possible to plot the trajectories orthogonal to the level lines. They too, when several of them are traced, have very interesting properties. Orthogonal trajectories and level lines should not be drawn on the same figure.

Almost nothing comes out. Orthogonal paths

should not have the segments of the polygons present, only the vertices. We can

not develop in more detail the considerations on the eifs, ifs, avæcum, components of

the avæcum, pavs, states, atmospheres, vital fields, etc. which can be detected on the families of curves. We can avoid drawing certain level lines in the case of fields  $f(M)$

$$\sum_{i=1}^n M A_i$$

where the  $A_i$  are the vertices of the regular polygons or dodecahedra. First one can only draw a few lines, the more one draws the more powerful the avæcum; the idea is to try to have the shape and the level lines of the field. For this, small crystals can be added at the points  $A_i$ .

For some, one obtains a very powerful avæcum because everything forms as if the

sheet of paper, level lines are not detected outside the edges of the sheet. In the case of polyhedra, the level surfaces are detected throughout space, the polyhedron must have its faces; we no longer detect anything if there are only the edges. In the case of the Platonic polyhedra, they additionally become hard cores. In the particular case of pearl dodecahedrons (with perforated faces) if a person wears one at the level of his forehead and another person, even very far away, wears another, of the same type, also at the level of his forehead, and that moreover, the two people think of each other, then a transfer is established and the level surfaces are detected around each dodecahedron. They can be used to contain information that will pass from one person to another. This does not mean that the beaded dodecahedra were used like that or only like that.

Let's go back to the launch of the C. de C.; either A this launch, or B which corresponds to the dilution of the obs in the C. of C. Of all this the obs only perceives an echo, either C, which it filters, or D.

Let's put this on a T AG system, i.e.:  $\wedge_{bs}$

It should be noted that in this construction no time intervenes, there is no before or after. The tackle on the T AG system requires cells C and D to be in place, as well as the separation between the two, as well as the locations in these cells, symmetrical, A and B. The Obs is tackled on the corridor of separation (the ancients would have said that Man balances). In reality there is only one obs, everything that will come next, and there will be an after, is the consequence of this tackle on the T AG system. In this tackle the obs throws his C. of C. which corresponds to position A and places himself in it, which corresponds to the position in B but he only recovers an echo from it, either cell C, that it filters (which it rearranges), i.e. cell D.

This will create an atmosphere, which will be the spread of multiplicity (by abbreviation: étamul). Then here comes a nuance in the cerebral process of awareness of the étamul.

By etamul:

- either only each human being is exterior

- or each human being is external and enjoys his personal status, which means that the Obs tacitly admits that the others are equivalent to him.

In the usual C. de C. it is tacitly admitted, although we are absolutely unaware of this step. In the other C. de C. we have the awareness of this whole approach but it is possible that there are R. de C. in which we only have the first part of the alternative. Let's see the second part of the alternative: the obs (O) can be considered as creating the individual I but according to this second part, I is equivalent to the Obs therefore creates the Obs. It would seem that O is not complete without I.

### Exercise :

Consider the following model: a circle M and a square N such that if N is inscribed in M, this gives a form P and the permutation between M and N, a form Q.

Considérons M et N as primers and P and Q as progenitors such que  $M|P \Rightarrow Q$  and  $N|Q \Rightarrow P$ . In P and Q, M and N have relatives ce-positions which makes P and Q not stable as the dessinées above form (1, 2, 3 and 4) but, the existence of M and N in P Q et les éand

ci contre (posed quimseys make that we have the following shapes,

L'équimsakes it possible to account for the fact that the forms M and N

assembled in the forms P and Q, are not

complete and that they

complete each other indefinitely.

But it is a question of making primers and equimseys.

a) check that to make the primer between M and P it is enough to place P

on a red carpet pierced with 5 holes, and 2 small circles are placed

It is best to center the small circles.

- b) Check that to make the primer between N and Q it suffices to place Q on a pale yellow carpet pierced with 2 holes and 5 small circles, placed as above.

Just swap circles and holes from the previous figure.

- c) Check that the M|P and N|Q equimseys can be made by placing assemblies a) and b) side by side and interposing a piece of graphite between them. Above the assembly c) one detects on what there would be by continuing indefinitely, such is the diagram of the figure marked 6.

Note :

Let's match the Obs O to Met an individual I in the coherence field of O, to N. The model used accounts for the fact that O creates I but which contains O which creates I etc. This is not quite the representation in usual thought; you can insert it if you want, but in this case it remains a mind game of no importance.

Exercise :

Another model can be considered, still for the last part of the previous alternative. Consider an isosceles triangle with base AB and two smaller sides. Let's construct two isosceles triangles similar to the first and so on. The outer contours have a fractal structure at the construction limit. Thus by this process one sets up the various stages of construction of a fractal object studied in 1938 by the mathematician Paul Lévy [3].

We will take for example  $BAC = 30^\circ$  or an angle less than  $30^\circ$ . Angles greater than  $30^\circ$  do not make it possible to obtain a fractal object.

At Obs O let us correspond to the triangle ACB; to human beings I1 and I2, in its representation it will correspond the first two triangles built on the sides AC and BC but like them, are equivalent to O according to O in their C. of C. and this by étamul.

Note 1 :

The two models considered can also be used to account for the cerebral approach of obs O because in reality, it is he who realizes his type of reasoning and becomes aware of his etamul. Etamul is for others as well as for oneself.

Other models are possible which involve only two stages. The importance of all these models is to have an understanding of cerebral gait.

Note 2 :

If we come back to the level lines, we said that they are revealers. We can put the brain of a human being in transfer with a set of level lines. If this transfer is well in place, or if necessary by adding an external line to the given set, we will increase its sensitivity and also the person concerned will increase his areas of perception. It is good to pierce at the center of gravity G of the equilateral triangle so as not to have equivalence levels that risk bringing unforeseen effects. We can put a witness in the center; the baton should not be left for too long. All this development about the field  $f(M)$  envisaged previously constitutes multiple variations on a form.

Exercise :

Avæcum can be obtained from stakes planted in the ground. The stakes have the same length and protrude the same length from the ground. They are in the same plane and separated by distances satisfying several possible sequences of values. Their ensemble emits day and night. One can even engrave on a glass plate, parallel vertical lines, unequally distant from each other, but the intervals still satisfying very precise sequences of numbers. If you light from behind or even better in grazing incidence, the avæcum is very powerful. If we make an orthogonal affinity on the figure engraved on the glass, the ratio  $k < 1$  is even stronger. If we put

two such arrays of lines on 2 glass plates so that their directions are perpendicular, there is no more avæcum; the closer the angle is to  $0^\circ$ , the more avæcum is detected. Let us recall that when the angle is  $90^\circ$ , it is as in the cases previously indicated, the avæcum is not even detected at the exit of the barrel or more generally of the transmitter.

#### Exercise :

Consider a closed box. Let's drill a small hole in one of the faces. The box becomes a weak emitter of avæcum. But if you paint the inside in a matte black and it is still pierced with a small hole, check that it becomes a powerful emitter of avæcum. And this whatever its form. (If the black is matte, the shape takes on an ext).

#### Note :

Now we find here the black body which intervenes in the laws of the emission of radiation. So any black body emits avæcum. Moreover if in the black body, one puts a crystal of quartz, not too big compared to the volume of the box, one has emission of avæcum which is amplified. Obviously we detected the avæcum without any presence of black body. But every body has more or less a black body character <sup>10</sup>.

If, for example, a piece of polished metal (perfectly reflecting body) or a fragment of frosted porcelain (perfectly diffusing body) bearing spots of platinum black are brought to incandescence, these spots emit more light than the rest of the body and stand out in light against a dark background. If we test, we discover that they emit avæcum. On the other hand, sunspots do not emit avæcum. The black body has the character of what later we will call: hard core. Forms that are hard nuclei emit more and more avæcum over time.

If we arrange in the interior of the black body, plates with holes or not, in certain arrangements, we will no longer have an avæcum. Some signs drawn externally on the surface may increase

<sup>8</sup> The expression used in blackbody physics is poorly chosen; it simply means that at ordinary temperature, the black body, which neither diffuses nor reflects any portion of light which illuminates it, appears black - like lampblack or like the inside of an oven.

<sup>9</sup> It is stated in physics: the spectral brightness of a black body is independent of the direction considered, and of the nature of the walls. This is why we speak of blackbody emission and not blackbody emission.

<sup>10</sup> The brightness of any body, for any wavelength, is always lower than that of the black body at the same temperature. That is, of various bodies at the same temperature, it is the black body that emits the most energy.

the avæcum. We can even provoke a Dd between its interior and its exterior. We see that the avæcum is not identical to energy, first it is not localized, then we can make a black body which does not emit an avæcum.

A flame that contains a metallic vapor emits a spectrum of lines by incandescence. For example with sodium vapour, the flame is yellow and emits the double D line: the sodium vapors contained in the flame must be absorbent for this line. If the light rays coming from an electric arc are passed through the flame, and if they are then received on the slit of a spectroscopy, it should be observed that the radiations corresponding to the D line which were in the spectra of the arc have been absorbed; they have moreover been replaced by the radiation emitted by the flame. The brilliance of the flame is certainly lower than that of the black body at the temperature of the flame, approximately 1800°; the brilliance of the arc is much higher, of the order of that of the black body at 3500°: the D lines therefore stand out in dark against the brilliant background of the continuous spectrum. This is called the reversal of the lines; we know that it is by this phenomenon that we explain, since Kirchhoff, the existence of the black lines of the solar spectrum. Here again, the avæcum is detected in the black lines and it is placed in a three-dimensional neighborhood of the spectrum [4].

The avæcum can be obtained by surrounding bodies: for example an engraved cylinder rotating around its axis. The avæcum will be all the more powerful as the speed of rotation will be high.

Note that jade amplifies the avæcum (this varies according to the color of the jade). It can also be amplified by an assembly, at the exit of the guns, in the cross of Saint-André not circled, or circled, which is even more powerful. You can also use a netting with small square meshes (hexagonal, this would not give the expected effect) or rectangular (for these dimensions are more interesting than others).

Certain religious objects and motifs emit avæcum: for example the cross of Saint-Maur supposed to be from the 9th<sup>century</sup>. It is in the abbey of Saint Maur; this building is on the edges of

the Loire, near Angers <sup>11</sup>. It was occupied by eight Assumptionist religious. Now they are gone. The cross, which must have been slightly pattée, bears, for all ornamentation, mixed-line interlacing. The design in the center protrudes 3 to 4 cm; elsewhere the notch does not exceed 1 cm. The total height of the cross is 2.38 m. ; the arms are unequal; the one on the right measures 0.88 m and the one on the left 0.65 m. This is important because Ravatin and Dupré realized from marks made on an astrolabe made by Dupré, (which is an extension of a simpler one made by Don Néroman), that at the intersections on the sphere of the fixed l the ecliptic and the polar circle could be matched by a cross with unequal arms; on the other hand, the ratio of the lengths of the two arms is lower than for the cross of Saint-Maur.

The cross of Saint-Maur rests on a foundation of stones, several of which are decorated with drawings. Similarities have been detected with the stone cross from Carew, Pembrokeshire, England and the carved cross from Abellennno in Scotland. Drawings similar to those of this cross were found on sticks in the Dublin museum. It is these remarks that have been used to make a dating; it is therefore not certain.

In the center is an interlacing which is interesting because it emits avæcum and a quite powerful avæcum. We give a reproduction made on site by R. de Montercy. There must be voids for the avæcum to be detected. If the motifs on the branches of the cross are openwork, the avæcum is very strong. By slightly modifying the central drawing, we can while keeping the avæcum and even amplifying it a little, detect the FFV. The cross of Saint-Maur as it is, embedded in a wall of an old chapel of the abbey does not emit an avæcum.

<sup>11</sup> Abbey of Saint-Maur de Glanfeuil, La Thourel 49350 Gennes. For all information write to this address.

Complement :

Another example of a form that can emit avæcum but only under certain conditions can be found in the following story:

A few centuries ago, lived in the region of Trace, in northern Greece, a monk, hermit, named Father Demetrios. This man was famous all around, for he lived alone in an inhospitable region, according to the travellers, other monks and all the villagers;

moreover Demetrios seemed to live in the midst of great abundance; this was particularly evident because he offered plenty of food as a sign of welcome to his visitors.

One day a traveler passing through the region of Trace entered the humble abode of Demetrios; he observed on the interior part of the front door a cross; it was adorned with symbols and initials. The traveler asked Aba Demetrios what its meaning was; the hermit referred to a singular story which was kept in the library of a Greek monastery.

A certain night, Demetrios had a strange dream: an angel appeared to him surrounded by a supernatural light which made him resplendent. He spoke to him: "For the life you lead, heaven rewards you. If you hang this cross on the door of your house, you will no longer be tempted by the devil. Never again will you make bread and the fires of evil will be repelled". And the angel drew with his hand a cross surrounded by symbols and initials that Demetrios kept in memory with all the possible details and that he reproduced on waking.

Then he hung the cross on the door of his house, where the traveler discovered it, and he activated it by a special ritual. From that moment Demetrios fell into a state of bliss, absolute tranquility and peace. His life was blessed with an abundance of food. He reaped a hundred times more than he should have with what he sowed and his reserves, instead of diminishing, seemed to increase.

The traveler shared the monk's meal and got ready to spend the night at his place. The next morning, when he woke up, he saw that the monk was dead, but on his face he still had the same expression of inner peace.

The monks of the nearest monastery were notified; they came to bury the remains of the hermit and took away the Cross, the story of which was told to them by the traveler.

The miraculous power of the Cross was confirmed when, ten days after being placed on the door of the humble monastery, it received an important donation from distant Russia: a crown of gold encrusted with diamonds and rubies, which the Tsar gave because it had belonged to his father, a great devotee of Saint-Georges and also because the monastery was dedicated to this saint.

<sup>12</sup> In the case of the Curé of Ars, localizations of wheat were made several times as well as localizations of entities with which he conversed; witnesses saw and heard him talking.

The original “Cross of the Gate” remained there until today; she is still there and continues to bring in abundance her gifts of prosperity, bliss among the monks. The reputation of the place was growing in such a way that in the century when this story began, an Athenian antique dealer visiting the monastery stayed there for a while. Having also been able to benefit from the benefits of the Cross, he asked the monks for permission to reproduce it. They nodded and decided that one of the monks in the library would give the Athenian in question a parchment copy. There is a ritual to activate this form; it is not known exactly whether the details of this ritual were transmitted by the monks to the antiquarian. Finally, it should be noted that the antique dealer having taken it to Athens, he lived the rest of his life in great material prosperity and spiritual calm to the point that his house was known throughout Athens as “the House of the Cross of the Miraculous Door”. In this way the gift of Heaven given to a holy hermit to reward him for his life as a saint through the miraculous appearance of the angel, became accessible to other men.

Advice was given for using the Cross with indications for the ritual; it is unknown if this is the original ritual.

The cross should be hung on the main door of the house or office so that it faces inward. This is correct because if we test we see immediately that it is in a vertical position that it is most effective. If it is a field, it is advisable to place it on a palisade closing the field. Avoid placing it in a noisy or agitated place.

You can make different offerings of flowers, light candles (white), burn incense at this Cross. It may be noticed that it falls off sometimes, its gloss shows up differently, it may not appear in photos taken of it. This cross, when prayed in front of it, or if a ritual is performed, takes on interesting properties.

She takes an ext, then emits avæcum as well as VC, FV, LD, LA. It reveals itself through prayer or ritual. This continues over time as prayer and rituals are continued. It has properties equivalent to those of an icon. It is linked to entities (they are not FIs) <sup>13</sup> We find a case of the same kind in the miraculous water that comes out of the sarcophagus of Saints Abdon and Sennen in Arles-sur Tech. Before the distribution of the water collected in the sarcophagus, once a year, at the end of July, a procession takes place in the city. This is important but not enough.

<sup>13</sup> FI for Intelligent Forces or Firthes. These are combination effects of Arkhams and Mahkras.

As before, it takes either prayers or a ritual to reveal this water. The miraculous waters of Lourdes and Fatima are almost the same.

## Chapter XV

### */ . THE CITY*

We have seen that the avæcum has two components, but the experiment described below shows us that a new phenomenon occurs.

Let us put at the exit of the barrel, a piece of wood of circular, cylindrical section, the axis of the cylinder merging with that of the barrel, such that this piece of wood has on its surface a helix to the right or to the left, engraved. One no longer detects, in the extension of the system beyond the wooden cylinder, any avæcum, but there is something else. This is what we will call the “PAV”<sup>14</sup>. There will be a right PAV or a left PAV depending on whether the propeller on the wooden cylinder was on the right or on the left.

One can get the pavs using a Vyz shape planted in a cork and the upright stem put in a bottle. It is good to take a fairly plump bottle. By the 2 oblique rods it leaves for one the right PAV and for the other the left PAV. If you put coarse cooking salt at the bottom of the bottle, it's even stronger. If we put the system described above in a bundle of avæcum, the Pavs disappear, and we have an Æ pump.

If we have a beam of PAV D<sup>15</sup> and we put a plane mirror with 2 reflecting faces perpendicular to this beam, Pav D is transformed into Pav G. Likewise Pav G becomes Pav D.

If we continue the experiment by putting a second mirror cutting the beam parallel to the first, if the gun without mirror emitted a Pav D, it always emits a Pav D (idem for the Pav G).

If we put an even number of 2-sided mirrors, parallel to each other and perpendicular to the beam and intersecting it, Pav D or G is kept as Pav D or G. If the number of mirrors is odd, Pav D

<sup>14</sup> This phenomenon has a vague resemblance to the rotatory power of substances like quartz which have a circular birefringence with respect to light.

<sup>15</sup> R or L for right and left respectively.

or G is transformed respectively into Pav G or D. If a beam of Pav D or G is sent onto a rotating body, it is preserved but it is amplified.

Certain bodies of chemistry sprinkled by a precise wavelength, for example in the infrared, will emit one of the two Pavements. If we prepare this body to be pumps at  $\mathcal{A}$ , watering by another wavelength gives the same Pav.

In chemistry, we learn that so-called optically active bodies have special properties. There are those called levorotatory or dextrorotatory or the half-half mixture of these two genera which is called racemic.

If we place a racemic mixture in front of the avæcum cannon, nothing new occurs, we still have the avæcum. If we put levorotatory or dextrorotatory bodies, we obtain Pavements D or G. Life chooses the dextrogyre.

If we put in front of an avæcum cannon a crossed out square, we have the pav which we would obtain by putting left tartaric acid in front of this same cannon. By replacing the left tartaric acid with the right, we obtain the other pav.

To bar a square, we draw a segment exceeding the edges of the square and inclined at an angle of  $-23^\circ$  with respect to the line NFSF which is an axis of symmetry of the square. If we draw the segment symmetrical with respect to the axis NFSF, we obtain an instable shape. This form posed vertically at the exit of the barrel, contrary to the barred square does not emit any pav apparently because the whole system becomes untestable. If we make the square symmetrical to the barred square testable by additional shapes, for example, we obtain the other tile and the shape formed by the cannon and the square is then testable.

Let's see a shape that emits both tiles simultaneously: Consider a circle with center O. Divide it into six equal sectors by the points ABCDEF. Let's draw the diameter CF. Let IJKL be the respective midpoints of the arcs EF, FA, BC, CD. Let's draw the chords BI, DJ, EK, AL. They are parallel two by two. The figure constituted by the circle, the diameter and the four strings emits the two pavs. If we pierce the center of the circle, there are no more cobblestones

This figure is linked to that expressing the dynamism of the FFV. Indeed consider the non regular star hexagon ACEBFD. This is the one that represents the rhythm attached to the FFV. If we draw the interior bisectors of the angles  $FRF$ ,  $ADF$ ,  $RFC$ ,  $DAC$ , we obtain the four chords indicated above.

If we put this vertical shape parallel to a flat ice, reflecting side facing the shape, we amplify the tiles. If we place a second mirror parallel to the first and its axis (we take it rectangular for example) in the axis of the circle, it is even stronger. If we place this vertical form between two copies of the form expressing the rhythm of the FFV, the whole vertical, the planes of the forms parallel, we have a powerful avæcum but no more pavs.

## CHAPTER XV

### */ . Reading Actika pyramid*

Its proportions are very precise. This could have been constructed on the basis of the meter as a unit. We could have started from another unit, for example, a unit associated with the moment or one not depending on the moment, but attached to another phenomenon; in these different cases the eifs and states will be different. The more one is interested in an adequate unit, the more the properties already found are confirmed and others appear. But here we have given ourselves the side  $c$  of the basic square and we have sought the length of the side assuming it to be regular. We arrived at 2.26 C. We must place the shapes to be dynamized slightly below the middle of the height; in this small region there is a canal. The form placed inside must not have more than 15 to 18 cm of space so as not to disturb the pyramid.

Naturally, to operate under the desired conditions, the pyramid must be closed.

At the solstices new effects occur due to the "rain" of VC

We can draw from this study that the forms, by their multiplicity, can be used in many ways: their proportions, the place, the moment, the unit chosen for the dimensions, even several units can be put in place simultaneously all this will make that we will have a form which will be operative for the obs.

Naturally, to function correctly this pyramid cannot be placed just anywhere.

## *II. The FIRTH <sup>1</sup>*

Frédéric Dufourg had discovered and used what he called the "Intelligent Forces" [1]. It was also the partial title of his first manuscript, which unfortunately got lost. On the other hand, his second manuscript [2] has been published. This is the application of "intelligent forces" to the study of the "raw forces of matter of the three kingdoms".

We said in [1] that Dufourg insists on the fact that "the brute forces of the three kingdoms" can only be fully assimilated on the condition of associating the "Intelligent Principle" with them.

During our research we have, at a certain moment, come to the conclusion that we touch this "Intelligent Principle" or still according to the name of Dufourg, the "Intelligent Forces".

We will therefore find forms that will be said to be "linked to the Firthes". Note immediately that a living being is not necessarily linked to the Firthes. Inert forms can be linked to the Firthes: for example certain stones; they are found in the countryside, in brush, near rocky places, in paths.

A statue from Easter Island makes it possible to be in contact with the FIs This makes it possible to go much further than what Jean de La Foÿe had found about these statues who had only looked for eifs and states. In general the eifs were harmful. If we consider a set of statues, we have access to one or more IFs that can be manipulated simultaneously, which allows us to work with much greater subtlety. At the same time, the IFs are modeled, as they can also be modeled by the forms.

We can "channel" IFs through vertical planes. Several planes made by rectangular wooden or metal plates placed vertically on the ground, on the longest side, the plates not being in contact with each other, give access to the IFs. There are multitudes of IFs, their creation will depend on the assembly. We can associate angles and crystals: this will allow to have shapes linked to firthes. This is the case of dihedral angles or solid angles. When the crystal is removed, it is not bound to the firthes; for it to be, we can bring in an additional form.

In the case of plane angles, we do not take crystals but autioth. The manipulations are delicate; they can generate other phenomena which are not apparent at first sight.

<sup>1</sup> Abbreviation for Firthe: FI. This word is feminine.

### *HL Components of the avæcum*

It has previously been pointed out that the avæcum has two components: the avæcum can be separated into its components.

For this we put at the exit of the avæcum cannon a vertical plate pierced with holes according to the shapes cut out by A and B.

If we put form A in front of the barrel, the avæcum gradually disappears, even between the barrel and the plane of the form: the sinusoidal component appears.

If we place the 2 shapes on the beam, their plane always perpendicular to the axis of the beam, whatever their position in relation to the gun, we no longer detect anything.

Note about the avæcum that some gray-lead skies emit avæcum. If in a room we place a painting with the color of the previous sky as a background and very green trees in the foreground, the painting emits avæcum. The avæcum is detected in a volume slightly larger than that of a prism having the flat surface of the painting as its base and the edges perpendicular to the edges of this surface.

A dodecahedron, the faces of which are pierced with fairly large holes, put between the oscillators of the multi-wavelength oscillator of G. Lakhovsky, emits avæcum during the operation of the device.

#### *IV. Aether-bound forms*

There is a very particular type of forms which, when tested, appear to be "A-related", that is, there is an immediate connection between the  $\mathcal{A}$  and themselves. We do not know the nature of this link, we simply know that the form linked to  $\mathcal{A}$  has properties that are quite astonishing to generate avæcum, LC and LD or eifs.

There is a precious stone which is linked to the  $\mathcal{A}$  (one is a reservoir of  $\mathcal{A}$ , or a pump of  $\mathcal{A}$ ), it is Jasper. We will see several examples of  $\mathcal{A}$  pumps; they are also of great interest because often they make it possible to create avæcum or LC and LD, or eifs with high C. de T., and their flight or even FV and VC.

If one puts a stone which has a psychic field (CP) near a form which is a reservoir of avæcum, the CP is singularly amplified. (CP for related to the Firthes)

We have previously reported the following assembly: 4 avæcum cannons, identical, each placed at the vertex of a square and facing each other two by two along the diagonals of this square. If we test, we find that these shapes made up of the four guns arranged as described are an  $\mathcal{A}$  tank.

If the guns above are large, this can be very important. If you dip a tuning fork in liquid air, it becomes an  $\mathcal{A}$  pump.

By heating water in a glass container, itself surrounded by earth which is contained in an earthen pot, the earth becomes an  $\mathcal{A}$  pump; if we put plants in this soil, after cooling, they emit VC and C. de T.. If we take this water, put honey in it and heat it again, then the honey becomes a reservoir of  $\mathcal{A}$ . It is interesting to consume this honey.

An  $\mathcal{A}$  pump can be obtained from certain tin alloys which are melted in the sun; then coarse salt is sprayed onto the molten alloy; on cooling we have a solid mass which has an ext. By adding salts of certain light metals, the whole can emit avæcum.

Certain vertical walls built with parallelepipedic stones can, under very specific conditions, become  $\mathcal{A}$  pumps. Not all stones should be too perfect parallelepipeds. We would have the same with an imperfect checkerboard with black and white squares. Naturally we speak of an imperfect checkerboard but it should not be done just anyhow. If, on this imperfectly executed checkerboard, we put stones in certain places, we can amplify the pompous character of  $\mathcal{A}$ . One can also make a regular and hollow convex dodecahedron, put inside solid cubes quite small compared to the dodecahedron and arranged a bit like the stones above in the wall, then the dodecahedron becomes a very strong  $\mathcal{A}$  pump.

One can wonder if the blood, in the veins, is linked to the  $\mathcal{A}$ ; before going further, it is a question of knowing well what is called blood: we will not take into account the red liquid which flows from an incision made on the skin.

This liquid moreover has an ext, it is that of the individual from which it comes; if this individual has no ext the liquid has none either.

The blood in the veins (we don't know what it is) is linked to the  $\mathcal{A}$ .

The whole blood network, as a form: vessels, arteries, veins, is also linked to the  $\mathcal{A}$ , but the human being is not linked to the  $\mathcal{A}$ . Suppose that we can separate this network from the individual to which it belongs, and that we put it in a dodecahedron (here it is a simple mental experiment!) regular, convex, hollow, something new happens: the human being linked to the blood network becomes an  $\mathcal{A}$  pump. The dodecahedron is for the human being a kind of revealer. It is not that it allows the human being to become a pump of  $\mathcal{A}$ , it is that it reveals that it is a pump of  $\mathcal{A}$ . If, instead of starting from the blood system, one considers the nervous system and puts it in a dodecahedron in thought, one detects that the human being is a reservoir of another aether, than that, let us say fundamental, of the Boutard's little snakes. In the last two volumes of V.Rosgnilk's work, we had put forward the hypothesis of a multitude of aethers. It thus seems that the human being is a reservoir of two or more aethers.

<sup>2</sup> The position of the sun in the sky must be taken into account. These alloys are found in the so-called "tin" caps closing wine bottles. These capsules are increasingly being replaced by plastic or aluminum.

It will not be only the dodecahedron which will be a revealer. Other forms are too. The "revealing" shapes are very useful, because they allow to consider properties of shapes that have hidden properties. If we do not know these properties, we can hardly use them.

The dodecahedron considered previously is not a revealer for any human being. If we consider for example a human being who is born without ext, or who has a low FFV, this human being is not a reservoir of  $\mathcal{A}$ . This does not mean that another form will exist and will be revealing to him. The "revealer" cannot reveal what is not (in the sense of existence without reference points). The human being, from the moment when he knows that he is an  $\mathcal{A}$  pump can emit the eifs he wants, where he wants, in a place desired by him; but also all that we have seen previously and which are not eifs. This is the first time, in this study, that we come across "revealing" forms. The artifices reported by La Foÿe to detect the vital field of plants or the spectrum of a lit candle are "revealing" forms. Here the technique of manipulation is more elaborate because it is necessary to consider an abstract form: the blood system for example but in the body, such as one does not know it seen from outside, and to plunge it by the thought in a regular dodecahedron, convex, hollow. Instead of such a dodecahedron, one could have taken a so-called "pearl" dodecahedron; it would have worked just the same. A study of this type of shape was made by J. de Saint-Venant at the beginning of the century [2] We present in the appendix a summary of the study by Saint-Venant.

Chlorophyll with a developer will give the VC. Hemoglobin with a developer will give the FV. For one as for the other, it is enough to take as developer a dodecahedron or a beaded dodecahedron, therefore to put them inside separately. If we put them together we will have both VC and F.V..

It is thus seen that the chlorophyll by this developer is linked to the magenta and that the hemoglobin is linked to the FV. The developer seems to detect a reversal made by the human being.

There are other "form revealers" than the regular, convex or beaded dodecahedra. For example, a language like Hebrew reveals forms; for that you have to take biblical Hebrew. Similarly, Hebrew letters associated with constellations promote transfer with forms. The Grail, the Tables of the Companions are revealers.

Ambergris is an  $\mathcal{A}$  pump. If we place ambergris in the center of a closed dodecahedron, we detect avæcum as well as VC, FV, LD and it is still an  $\mathcal{A}$  pump. Consider the 5 Platonic solids. Let us name the  $P_i$  where  $i$  is the number of faces:

- tetrahedron: P4
- cubic: P 6
- octahedron: P g
- dodecahedron: Pi2
- icosahedron: P20

Let's make a montage: P12 P20 Ps Pô P4 • If we place a brass wire such that they cross them all, this thread becomes an  $\mathbb{A}^1$  pump regardless of its length.

Léon Sprink did a study on iconography.

Forms, which can be revealed by a dodecahedron are the icons, but one can work on an assembly of circles thanks to which the icon is put in place. Sprink insisted a lot in his research on the traditional outlines having been used to establish the plans of the religious monuments and he noted that strictly identical outlines had been used for the arrangement of the iconographic representations [3]. He insists a lot on the fact that in the West or the East, the arrangement of the circles on the surfaces which will serve as a support for the frescoes, mosaics, and iconographic paintings is strictly the same as that of the surface of a plan of a church.

According to Sprink, in the West, there are very few documents that explain the significance of the layouts of churches and cathedrals. Most of them date from the Renaissance and are subject to question as to their validity. This is not the case with iconographic representations.

The Second Council of Nicaea was almost entirely devoted to the discussed question of the worship of images. His decrees shed vivid light on the purpose and significance of Christian iconography. This makes it possible to justify the complete identity of the layout of the plans of the churches with that of the icons. In religions other than Christianity, the worship of two- or three-dimensional figures is prohibited. The approach to the divine is very delicate: we must not forget that the realization of the figure is in the path of the one who will use this figure to contact the divine.

Sprink says: when we find ourselves in front of an icon “what dominates there is the impression of finding ourselves in front of a 'mystery', evoked and signified”. Of course, it is futile to look for even a two-dimensional AND structure in an icon. Sprink has this beautiful expression: "It is not, however, immobility in the current sense of the term, but the immutability of 'eternity'".

created". Sprink thinks that if the icons are in a plan, it is because, in our natural condition, this is the minimum still allowing an intelligible figuration.

It's not sure at all!

This is true, but there is much more!

It seems, when working with shapes, that planes are often more important than three-dimensional shapes provided the planes are, what we call, "inhabited." Sprink writes: "If on the icons... the arms, the whole body appear to us as atrophied, this is in no way a sign of unleashing, but the absence of possible and corruptible flesh", thus linked to the sensible world, and as a presentiment of the glorious body with all its qualities (subtlety, transparency, etc.) which place it outside the phenomenal order" and he points out that it would be a grave mistake to assimilate icons to abstract art. This body is close to the spiritual body of which Saint Paul speaks. The icon could be compared to an attempt to open up to a mystical experience. It allows relocation. If the one who prays in front of the icon, moreover the prayer reveals it, puts his thoughts, these can be placed in the revelation which contains a leak, and be placed in the leak where there will be a localization which will give animated images, but also containing eifs, states, atmospheres linked to the divine which further amplify the effect of localization in flight and stabilize it but take nothing away from its life.

Sprink talks about the impression of life given by the beings depicted in the icons. This is already the beginning of the process of leaking and filling the leak.

As early as 787 the Fathers of the second Council of Nicaea expressed themselves thus on the subject of the outlines of icon painters: "The composition of religious images is not left to the initiative of the artists; it comes under the principles laid down by the Catholic Church and religious tradition".

And again: "Art belongs to the painters, the ordering and arrangement (of works of art) belong to the Fathers".

Sprink talks about the colors with which the icons shine; he says that to find similar ones one would have to be in the steppes and deserts or high mountains before the day lights up the sky. But he says that icon painters have gone even further thanks to the "assiste", these thin rays of gold which weave a transparent veil and, suddenly, attenuate the contrasts of the colors of the refracted light. They signify light like that of Mount Tabor, which, moreover, icon painters have only ever been able to "signify" since it is outside our means of expression and representation. It's always about localization in the leaks where the color varieties, or maybe even the concept of color takes hold, breaks up the global and flows a bit into the

decalaire to fill, fill the leak. "In the West, the saints are represented as they were among us, in the East they are represented in the "ævum" or "created eternity", as they have been assumed, transfigured and "realized" in the 'brilliance of taboric light' writes L. Sprink.

Christ has been represented on an icon. This meant that the Virgin and Saints could be represented. All the theology of icons is contained in this lapidary text which claims to be from Saint Paul: "The Son is the image ("stxcov") of the invisible God".

Most Russian theologians recognize the sanctity of icons and the liturgical function they perform through their form.

By adopting this point of view, the Church of the East recognized in the ritual icon the sign of a supernatural presence; its liturgical meaning is based on a resemblance to an archetype living in another world than our phenomenal world. It must be understood that with these concepts, man locates.

Sprink writes: "Invited to choose from a rich album an image of the Virgin which best reminded her of her "Belle Dame", Bernadette put her finger, without a shadow of hesitation, on an icon of the 11th century, preserved in Cambrai. . Neither the virgins of Raphael, nor that of Murillo or Velázquez have found favor in his eyes" and L. Sprink continues: "Because, in the end, that is what an icon is: materialization of the prayer and flower of the contemplation ". The so-called "symbolic" Virgins shed striking light on the main lines of Christian iconography. For example, the "Virgin Orante", standing, hands raised, as described by Sprink, symbolizes the Church. She is often depicted in the apses of old churches in Russia (the oldest dates from 1035; it is in kyiv).

Saint John Damascene said: "Do not imagine the divinity, do not disguise it as the blind men that you are, because it is impenetrable for your gaze. By figuring the camel envelope, I bow down full of faith and I glorify the Virgin who gave birth to the Lord". (You should know that this text is not found in the writings of this saint, but that the content is consistent with his teaching).

Marian iconography becomes a replica of the holy liturgy which never tires of signifying in the same texts, mysteriously interchangeable, as Sprink points out, sometimes the Mother Church, sometimes the Mother of Christ who never ceases to give birth to her Body Mysticism for Life

eternal. Taken in this light, the icon of the Virgin-Church appears to us as a triumph of pure interiority<sup>3</sup>.

We see that the concepts Church, Mother Church, etc. are not attached to the rational C. of C. To understand them, it is necessary to use developments of the kind presented in the study, inserted in [1], on the World of Silence by Max Picard.

It should not be forgotten that adoration is strictly reserved for icons of the Saviour; those of the Blessed Virgin and of the Saints are only venerated.

Sprink places great emphasis on icons so that the minds of the faithful of the Christian East may grasp their meaning. He sees a certain equivalence between the writings of the great mystics of the West (one thinks in particular of the Rhenish mystics and the Flemish mystics) and the icons of the East; on the other hand in the East the texts are rare.

You have to have been in the contemplation of an icon to grasp its secret meaning which immediately puts it at the extreme limit of the usual local. An RBB cannot address these states and this domain. Let us quote with Sprink the curious phenomenon called in Russia "prosvietlenie". It has been common in Russia since the great revolution of 1917. It has been attested by countless witnesses. Icons, very old, blackened by the smoke of candles and nightlights that had been burning in front of them for centuries, with their varnish ruined by time, suddenly recovered, overnight, all the freshness of their colors and their primitive brilliance.

Similarly, some domes, tarnished by age and lack of maintenance, suddenly "lit up" and shone as if they were golden yesterday. This mysterious phenomenon concerns above all the icons of the Blessed Virgin. Obviously, adds Sprink, one could not expect, in the present circumstances, a formal investigation or technical verifications, but the testimonies on this point are so numerous and consistent, spread over such a long period, that it would be very difficult not to take this into account. From the 1917 revolution, a new atmosphere began to emerge and there was impregnation on the icons of this atmosphere. Those of the Virgin were perhaps in their construction more apt to react? [3].

<sup>3</sup>It is quite significant that the iconoclasts who fought excessively against all representations of Christ, of his Mother and of his Saints, nevertheless admitted a holy icon, a sign and image of the presence of the Lord, the Eucharist.

“They knew almost everything; nothing seemed to be  
difficult to them, neither cutting nephrite nor melting gold, and all that, arts  
and sciences, proceeded from Quetzalcoatl”

: i :  
Brother Bemardino of Sahagun

This is from a chronicle of a cleric who was with the conquistadors during the destruction of the Indian civilizations of the Americas.

The Spaniards were chosen to accomplish enormous destruction in order to gradually put in place a system which now reveals itself to us as the meaning of a gigantic puzzle. [Recall this thought of Cortez on the destruction of Tenochtitlan: "He was sad to be the instrument of its destruction but it was part of our plans and we had no choice". It is obvious that a historian will not understand this remark in the sense in which we take it. It is too steeped in rationalist propaganda!]

It should not be forgotten that the machinations are not revealed in the Histories of the Peoples, so all knowledge is distorted.

This remark by Brother Bemardino de Sahagun illustrates perfectly the incomprehension of the rational thought in which he was immersed - with regard to another thought - attached to the other Field of Coherence -, the Indians, because of what we call their god and their gods, that is to say their mental constructions which were in a R. de C. of the Other Field of Coherence knew how to use these entities, because they existed in this R. de C. - Moreover, perhaps there were several R. de C., one for each civilization: Olmec, Maya, Toltec, Zapotec, Incas.

Moreover, some R. de C. may have been very close as in a R. de C. beam due to their similar polarors (it is recommended to refer to [1] where the Theory of C. de C. is presented). C. from a model where wandering points are used to set up the R. of C. and the swarms of coherence) which makes civilizations seem to follow each other while they mix by similarity of R. de C. Their differences would be the expression of the structural differences of R. de C. .

The god and the gods become the very structure of R. de C.; it is enough for humans to traverse this R. de C., at the same time they construct it. “They are what they are” one could say. They are in becoming, which is the expression of “being being”, that is to say, the Idathema.

For an outside observer, who is not the adequate thought, "they ask and it is given to them," so he sees and then does not understand that it is a question of the structure of R. de C.

The conquest by the Spaniards, this Indian genocide, were the fact of bringing together a bundle of usual R. de C., thus there was destruction by assimilation by rational thought, and this with a goal - since the goal exists being given that we are talking about habitual thought - which becomes more localized every day.

Outline of the icon of Our Lady of Vladimir  
 (It was chosen by the Church as a sign of unity on the eve of the Council)

Layout at the request of L. Sprink de J. Grivot, architect DPLG

Let's draw the circles. By adding the rhythm form attached to the FFV, we have a transfer with the icon, moreover we detect avæcum if the plane is placed vertically. It is an Æ pump.

If we rotate a gyroscope in a dodecahedron, the whole becomes an Æ pump and emits avæcum. Gyroscopes are very important; they have been used in devices that can

overcome gravity. The RBBs persisted in claiming that these devices did not work. And yet they worked! It is necessary to associate several gyroscopes. It's good to have three. It is then observed that the apparatus becomes a pump at  $\mathcal{A}$ . This is not enough to make it 1 avoid, but we realize that we are not in front of a technical object (OT), but of a phenist object (OP). As pointed out in [1], the conservation laws of rational mechanics do not apply to such systems. One such device is Eric Laithwaite's machine: it has only two gyroscopes which are driven by a motor and can move on a helical upward rail.

Let's go back to the regular convex and even beaded dodecahedra. We realize that a constellation like the Little Dipper is linked to the dodecahedra. Let's do the following setup:

The dodecahedron becomes an  $\mathcal{A}$  pump but does not emit an avæcum. If we look at the Little Dipper through a beaded dodecahedron there is an effect on the viewer. Of course it is very subtle.

From the rhythm shape related to the FFV, we can derive two planar shapes. Both forms have very interesting properties.

First they are linked to the  $\mathcal{A}$ , they have an ext and an int. They send out avæcum very strongly, whether they consist of a single thread or plates.

(We have reported the figures that we had put on the rhythm form of the FFV) <sup>4</sup>.

The plates are: M1N4, N5P2, P3Q6 - or the trace with a wire: M123Q654M.

If we put the plane of this shape vertically and parallel to the lines of the faces of a magnetic field, we amplify the characteristics indicated above. On the other hand, if the same amplification property is desired with an electromagnetic field, the vertical plane of the shape must be placed perpendicular to the propagation vector of the field.

If we place this form parallel to a mirror, it is even stronger and we associate curved surfaces with the form. The same is true for the other form. These two shapes can be placed in perpendicular planes. All the characters are reinforced, except that the associated surfaces are replaced by a volume. It is further amplified if the line of intersection of the 2 planes which is an axis of symmetry for the previous shape, is vertical. In these last two cases, we can place these

<sup>4</sup> In this case arcs 1.4,4.2 , etc. are considered equal. Other FFV patterns where they are not equal exhibit the rhythmic form associated with the more operative FFV. One can thus generate, without coloring the forms-rhythm-which resemble the seal of Solomon - VC, FV, LD, LA, LC, LB.

two forms in a magnetic field; this must be parallel to the earth's magnetic field for the avæcum to always be detected.

But each of these shapes can be replaced by suitably arranged angles. These angles can be plane or dihedral. If they are flat, they are inserted in a rectangle, if they are dihedral, they must be in a parallelepipedic box. The two forms could not be placed on top of each other without losing the avæcum. With the angles, the tackle is possible, the avæcum is even stronger. We can even, if we stay in the plane, avoid drawing the rectangle completely. In space, one can also eliminate the box and only use dihedral angles <sup>5</sup>.

As we pointed out in [1], angles have amazing properties. In some cases on the study of forms, we replace them with systems of angles. We can also have in the case of the plane, angles with rounded points, the same for the dihedral angles and the solid angles when we are in space <sup>3</sup>.

A full 16° apex angle cone emits avæcum and is an Æ pump. It is the same for a full cone with an apex angle of 74°.

One can ask the question, as for the lengths, to know if there exists an angle which can be imposed like unit and which is connected to a unit of angle. For the distances, we know that there were multiple cubits depending on the places, the times, so we had forms linked to the moment and transported, they could enlarge the moment. The meter is not a limit that allows the operations of the previous units. All these old units were not operational; there were only some. On the other hand, we cannot compare some of these units with each other and in particular with the meter without deleting the operativities of the shapes which are constructed using these units. So if we want a shape, for example a parallelepiped, to have such a property, we can find a unit that will allow us to locate this shape and above all it will have the desired property. If we copy this shape by measuring with a meter for example or one of its sub-multiples, the newly constructed shape, apparently similar, will not have the desired property at all. It will be much more localized than the first.

<sup>5</sup> One can place for example these forms and these arrangements of angles in the energizing pyramid mentioned in a previous chapter. It takes on amazing properties. In particular, this pyramid is associated with curved surfaces in the case of the first two forms and a volume if they are used together as we have indicated.

But we can find a unit of length linked to the meter which makes it possible to compensate for these units attached to a shape. In the same way one can find a unit of angle, these two units are moreover related. The angle unit is related to the degree; it is:  $2^{\circ}3'$ . We can use the usual protractor to measure the angles but we will bring them back to this unit to find the desired angle with the pendulum. Here the case of the solid angle is not solved because there is the number 7C.

We can take the form of the rhythm linked to the FFV with angles. The latter will emit a lot of avæcum. She responds to FFV <sup>6</sup>. It is necessary to mark all the angles and keep their locations in the figure obtained by the first drawing <sup>7</sup>.

<sup>6</sup> It has no ext while the FFV has one. If it is made with dihedral angles, it has an ext. Note that the dihedral angles have the same value as the angles drawn in the plane. These angles can also be embedded in a closed cylindrical box, their edges must coincide with the generatrices of the cylinder.

<sup>7</sup> Let's use the Hebrew again: the H is linked to the  $\mathcal{A}$ ; YH is a reservoir of  $\mathcal{A}$  but not HY. YH is an abbreviation of "Etemel". Note that the wormwood plant is linked to this YH. It is linked to the FIs YH is linked to the FIs and this is what links absinthe to YH. Consider YW and put an H in different places on YW, HW, Y WH and even another H, we get YHWH.

This allows a collapse in YH. Note that:

- hA Sh fire

- YH abbreviation of the "Etemel" the Man actualization of fire
- hAYSh

- hAShH the Woman, the living fire

then Y,H in equimsey gives hA. A shin arrives; it separates the equimsey; we have: hAY and hAH then it is formed hAY-Sh and after hAYH. Then hAY-Sh becomes the hAYSh.

This confirms the importance of angles. Moreover Francis Warrain in [4] writes about geometry: “The neutral element is the Angle, because it is the angle which allows the diversity of the radii and the determination of the curvatures. Finally the Angle is the source of all spatial metrics. Indeed, it is as a chord of a circle that a segment can constitute a standard of magnitude due to the fraction of a circle that is associated with it. This fraction is no doubt arbitrary since it depends on the radius chosen, but this choice made, the segment is qualified by a structural relationship between the part and the whole. On the contrary, a line segment compared to the other will only give similarity ratios without fixing any unity inherent in the geometric structure”.

Should we deduce from this that homothetic or more generally similar figures have the same properties for what interests us? Regarding similarity, this will not always be true because there are relationships that can cause a shape to take on new properties in its neighborhood after a rotation. As far as homotheties are concerned, it should not be forgotten that the obs is submitted in its tests to its tacit knowledge and in this knowledge is the chosen volume of space. The properties are not the same according to this volume of space.

So it seems that distances should also be brought into play. On the other hand, if we assume that the two dimensions are as fundamental as three, we can describe in a plane a network in which the obs is placed and the identification of a form by this obs is not a point but a finite set points on this network. The distance from the obs to this shape is then an angle or a system of angles. This is necessary if we want to account for the mental displacement of the obs in his C. de C. as well as the existence in this same C. de C. of other obs which are only put in place by him. .

Three-dimensional space emerges from these planes. Plans also come into play when accurately observing the twenty-two Hebrew letters (Biblical Hebrew). To this set of twenty-two authioth corresponds a set of twenty-two planes. Note that an ant does not correspond to a precise plan.

Simply these two sets have the same cardinality. We can have the traces of these twenty-two planes on a horizontal plane (none of these planes is parallel to a horizontal plane). These twenty-two planes have an ext (the set) and the FFV is associated with them. They are also associated with a volume shape. They are not linked to the IFs but can easily be arranged for them to come into contact with a wide variety of IFs. If we put the traces reproduced on paper in a cathedral, this set behaves like the set of plans. If we put them in the pyramid

energizing effect considered previously, a very powerful avæcum is detected but there is no FFV nor is it an Æ pump.

There is a flat layout of 28 points which creates a very strong avæcum; this has an ext and is an Æ pump. Let us replace these 28 points by two representations of projective geometries each on a plane surface (we will pay attention that in the representations of projective geometry, the straight lines are arbitrary lines); the two surfaces being in the same plane but separated by a corridor. For one geometry,  $k = 2$  and for the other  $k = 4$ , which means that the total of their points or lines is 28. These two representations being arranged as we have just said, we find, if we send l 'avæcum in the corridor, the two components of this avæcum; if the two geometries are in the same plane, but without common point, one detects a very powerful avæcum, it is a pump with Æ and that has an ext.

Let's go back to the 28-point planar layout; one can further amplify the avæcum and the pomp character in Æ by placing a copper winding above the board where these 28 points are made by holes, or from below.

If we pass the wire through the holes, crossing the board, we destroy any avæcum and the assembly is no longer linked to the Æ. The current, if a current is passed through the winding, transport of the avæcum. But we can link this plane figure with 28 points to a rhombus either in volume, or a flat figure representing a section by a plane of symmetry of this rhombus. There are also considerable amplifications of everything previously reported.

Let us say a few words about these two-dimensional rhombs: they have been described by Jean Servier in [5]. Servier presents it as a tongue of wood or metal placed at the end of a rope or a strap that a man turns at arm's length. The man turns at the same time on the object. There is a whirring sound as it rotates. The Dogons, the Aruntas (Africa), the Bombaras (Africa) say that the rhombus was passed on to them by spirits or was carved out of acacia wood, a sacred tree, recognized as such by initiates. In Africa the rhombus is often linked to the initiations of men. Similarly, the rhombus appears as an initiatory instrument in the islands of the Torres Strait in Melanesia and in the Solomon Islands.

In Malaysia, it is used by shepherds to ward off wild animals.

<sup>8</sup> The 28 points are linked to a deeper notion, which is that of the Æ crystal. On the other hand the Æ is stronger if one places oneself in a plane parallel to the rays of the sun.

In Ceylon, it is associated with certain Buddhist ceremonies.

Often, and in very different places, he seems to have a formidable power over women.

In America, it is known to Eskimos, Apache Indians, Navahas, Koskinas, Kwakiutls (British Columbia), California Indians, Pueblos (New Mexico), Hopis and Zuni. It is used in the latter to invoke clouds, thunder, rain.

It is still found in central Brazil where it is used to keep women away from the mysteries performed by men.

This instrument is found in Scotland, in Cantyre, in the County of Argyll where it is associated with an ancient celestial god. In the County of Aberdeen, cowherds used it formerly (even still in 1885) to protect their herds from lightning; Servier does not give any recipe. The rhombus is found in the Basque Country: it comes in the form of a slightly jagged wooden board, the shape of which is no longer that of the flat rhombus we have discussed so far. It is attached to a rope and the shepherd twirls it so that the humming keeps the mares away from the herds, these beasts being able to frighten the sheep at night. It is also used in Béarn to ward off mares seeking to enter sheep pens.

It is also found in Sicily and Portugal. In this country, the elders forbid children to sound their rhombes at harvest time.

People in prehistoric times had rhombs: one was discovered in the Magdalenian layer of the Grotte de la Roche in the Dordogne. Some have even been covered with ochre. They bear incisions corresponding to partial representations of manipulations of the  $\mathcal{A}$ . In Greece, the rhombus was present in the mysteries of Bacchus, Cotytto and the Mother of the Gods. They have been discovered in gold, bronze and even cut in rare stones.

Pliny reports that in her time, in Italy, it was forbidden for women to walk on the roads while twirling their spindles because it was believed that this could compromise the success of the harvest.

If we spin a rhomb flat or in volume, we detect a powerful avæcum but the rotational movement must be in the counterclockwise direction. If we make the movement clockwise, we have no avæcum at all; a state is created |K Sh Ph with reversed Sh>

<sup>9</sup> It is indeed necessary to avoid that this state is placed on the harvests but is this the only reason for the prohibitions?

Rhomb from the Roche cave (Dordogne)

Australian bulldozer

Central Australian bulldozer

New Guinea Rhomb

<sup>9</sup> If therefore, we turn in the wrong direction, there is also disappearance or rotation of 180° of the vital field of living beings.

Rhomb of the Bororo Indians of Brazil - Matto-Grosso

Greenland Eskimo Rhomb

Rhomb of the Basses-Pyrenees

One can notice serpentiform designs on these rhombes. Are they a reminder of Louis Boutard's little snakes [1] or of the orange component of the avæcum? Is there a link between these serpentiform signs whether they are the components of the *Æ* or the avæcum? We do not know it !

#### APPENDIX I: The "pearlized" dodecahedra.

These curious and strange objects greatly intrigued their discoverers.

It was in Germany that the first somewhat general study on the subject appeared in 1892. Professor Couze <sup>10</sup> enumerates in this study all the openwork dodecahedrons that he was able to identify at this date. It happens to fourteen different. It gives for a large number of them, the external dimensions and openings for the faces. He tries to find probable uses for it.

<sup>10</sup> Director of the Archaeological Institute of Berlin.

All are foreign to France [2]. He mentions in postscript a specimen found in Hungary.

In 1894, Professor Erman from Lausanne, presented in [2] an article about one of these objects found in Avenches. Twenty-four specimens appear in tables but without other details than dimensions of openings.

He also very judiciously discusses the various hypotheses put forward for their destination. He cites a new repertoire of these objects for Germany, plus eight new dodecahedra reported for France by Héron de Villefosse. In France these objects are in public or private collections: Louvre, Lyon, Poitiers, Rouen, Vienne, Troyes and collections of the Society of Antiquaries of London, of Messrs. Courtot, Bayer, Jouandot, Ponroy, Bertrand, Melines <sup>11</sup>. Saint-Venant describes or points out forty-one dodecahedra. About thirty are intact or have only suffered slight accidents: torn balls or damaged faces, but one can easily imagine their complete original shape.

Twenty-eight specimens have a known origin, but as Saint-Venant points out, it is hardly specified with really useful details except for 9 of them (openly Roman environments: former camps or various ruins). In 3 cases out of these 9, we can cite with precision the fourth <sup>century</sup> of our era as the probable date of their burial. 13 are of unknown provenance, and 2 have disappeared. A serious study on one of them is given by Saint-Venant at the beginning of his work. It is, at the beginning of the year 1906, the discovery made by gentlemen Machecourt father and son who were breaking up a courtyard to transform it into a garden.

About a meter deep, they came across, near the foundations of old walls, in a hiding place, ancient coins with teeth and bones of animals, fragments of knives, tools, iron nails, pieces of tiling, earthenware vases, shards with a micaceous surface, a life-size stone finger, fragments of Venus Anadyomène enterre blanche by F Allier, a piece of disc (diameter: 96 mm, thickness: 27 mm) in polished black stone, containing crystals in its paste (basalt or shale) pierced in the center with a regular bitruncated conical hole (diameters: 12 mm and 22 mm), two curious spherical glass caps, polished on their convex part (diameter: 76 mm and height: 40 mm).

There were 1672 bronze coins. The least ancient bore the effigy of Valentinian and date back to the end of the 4th <sup>century</sup> AD. <sup>11 12</sup>

<sup>11</sup> Naturally, it would be necessary to do research because these stories take place at the end of the nineteenth century, the

<sup>12</sup> On a property in the hamlet of Moiry, commune of Saint-Parize-Châtel in the Nièvre.

The others were by Gallien, Probus, Carus, Constance, Chlore, Hélène, Constantin, Licinius, Crispus, Constantine II, Constance IL. was about 30 cm from the vase where most of it was.

Let's see this object in detail: at the 20 vertices are buttons, not at all spherical with a diameter of less than 10 mm. The 30 edges of the solid are about 27-28 mm, the thickness of the metal is 1-3 mm, its height is 59-62 mm. The 12 faces are drilled in their center; the circular openings have different diameters: they seem cut out of the bronze plate but there is no trace of beads on the edges. The smaller holes are surrounded by equidistant engraved circles.

Let's see their general characteristics: it seems that it is a delicate and neat casting work that could only be practiced with "lost wax". The heights of the dodecahedra vary from 40 to 85 mm (this obtained for 32 dodecahedra).

The diameter of the balls varies from 5 to 10 mm. The circumferences concentric with the holes are of variable number and of variable diameters. Small circles are arranged on each side.

We therefore found them in France, Switzerland, Hungary, Germany, Holland and England.

Léopold Hugo, nephew of Victor Hugo, published short excerpts from notes to the Paris Academy of Sciences from 1873 to 1877 on pearl dodecahedrons. It seems that the Academy never took their author seriously and it was only thanks to his uncle's recommendation that they agreed to listen to him.

In conclusion, it seems that among these objects, those which could be dated, go back to the Roman imperial period; a certain number have been found in particular in the ancient camps near Germany. The discovery of Saint-Parize-Le-Châtel (Nièvre), makes it possible to specify even better and to affirm that they were in use in the 4<sup>th</sup> century AD.

These dodecahedrons intrigued their discoverers and many other people: their uses were supposed to be very diverse:

- scepter pommel
- masses of arms
- aspergillum
- candlestick
- cylinder gauge
- coin blank gauge
- game instruments
- ball game box
- variety of bilboquet...

It seems to be quite different, especially when you realize that there is an effect in the brain of someone looking at the constellation Ursa Minor through a beaded dodecahedron.

If we consider a hollow dodecahedron, beaded but whose faces are not perforated, it has an interesting property: everything is formed as if we had drawn the level lines of the scalar field  $f(M) =$

$20_1$

$1=1$  this creates avæcum which is further amplified by the presence of the dodecahedron. If there are

holes in the faces of the dodecahedron so there are no level lines. If we place one of the holes against the eye and look through the opposite hole at a constellation like the Little Dipper, the dodecahedron takes on the properties of the previous dodecahedron.

It turns out that by adding the balls with vertices of a dodecahedron, it becomes a powerful emitter of avæcum. It's a similar approach to that of Boutard or the Abbé Boudet [6] in linguistics and philology, they permute syllables, letters, make comparisons of phonemes between languages; this allows access to another very rich knowledge. This method could be applied in the countryside where one can easily by moving stones, modify a landscape on the horizon. Eifs appear but also states, atmospheres and phenomena can occur by localization or delocalization. But also, this process

can evoke new ideas in the person involved in this implementation. And this method can be applied in the field of the implementation of ideas. It's a very creative process. Forms will appear and be revealers. The people who especially criticized Boudet (there were more than for Boutard because the latter was less known) absolutely did not understand his

approach.

The philologists of the time of Boudet could not know the cerebral gait of the abbot; this approach may only work well for him and only with him, but let's insist, this revealing process leads him to new horizons.

But the beaded dodecahedra have a remarkable property: they correspond to paths in the sense in which we spoke about them previously: that is to say, a form  $F$  close to a beaded dodecahedron or on which one is placed, becomes  $F'$  by a route  $F$  with pearl dodecahedron  $\rightarrow F'$ . This is very useful in radionics. Wires passing through a beaded dodecahedron take on special properties; depending on the metal composing the wire and the entry and exit holes, the wire is linked to  $\mathcal{A}$  (æther) or emits eifs, yews, etc.

One can even associate planes with a pearl dodecahedron. These will be useful for transmitting information remotely between 2 people each having such an object.

The strata (see [1]) associated with a pearl dodecahedron are not clear for their detection.

Let us point out a curiosity: the lenticular bases in vitreous paste.

Scale 1/2

The ruins of Moiry yielded, among other relics, two large pieces of coarse, opaque, blackish glass bases: one 77mm in diameter, 37 in height, well polished on the outer part of the cap; the second of 75 x 42, rougher and seeming to contain sand; a few bubbles make its interior cavernous.

These very typical objects are beginning to be reported almost everywhere <sup>13</sup>, but we are not yet in agreement on their use. They are characterized by a spherical cap or flattened domed figure, the convex part of which is usually perfectly smooth; the opposite face, more or less hollow in the center, resembles an umbilicus, so the section is somewhat bean-shaped.

Some authors have spoken of similar bases, among others MI Dumuys and M. L'abbé Harrdel.

La Nièvre provided three others: two which appear in the Museum of Nevers and the third belonging to Mr. de Flamare, archivist of the department and coming from Nevers itself.

A broken copy at the Auxerre Museum, one at the Blois Natural History Museum, two at the Carnavalet Museum (one light-colored and one black). Orléanais and Blesois provided several of them, among others in Roman (and Gallic?) burials. Picardy, Normandy, Poitou, Champagne, also delivered some, almost always found in Gallo-Roman environments.

Mr. Demaison, in connection with a specimen collected at Reims by Mr. Mowat, thought that these pellets were used to grind colors and several of them would have been found, according to him, near old potters' kilns.

The Museum of Edinburgh also possesses some, and one is figured in its fine catalog (p. 274, fig. 148), where it is described as intended to polish or unite linen; the Museum of Stockholm contains many of them, it is said, which come, among other things, from the tombs of women.

The Scandinavians see it as polishers and in some provinces of their countries, women still used it at the beginning of the century to iron the linen; it seems that it is the attribution which must prevail as the most probable one reads in a work.

But it is to misunderstand the forms and if one places this glass form between the hands, it begins to emit what we call the fields Z, ZD, and the P-fields and the same from the avæcum. The Ancients were very attached to form.

<sup>13</sup> This is the end of the last century, beginning of this century.

APPENDIX: II We still insist on a point of view that we evoked in the volumes let 2 [1]: that of the Representation.

To illustrate what follows, let us cite an anecdote: Near Angers, in the countryside, R. de Montercy and P. Godart were studying a place in which there is a menhir.

Note that avæcum was found (detection by pendulum or rod) almost everywhere, which Montercy and Godart had verified. Montercy noticed that there was no avæcum above the menhir; Godart confirmed this.

Shortly after, P. Godart discussed it with J. Ravatin and C. Glaudel; them, found of the avæcum above the menhir as in the entourage of this stone and all the area. We are faced with a contradiction it seems? The approach of the dowzers more or less RBB, which one meets most often, would adopt the point of view of the contradiction. Yet they sometimes disagree. They would rather ignore each other than understand!

Is there a preponderant point of view on the other?

- the avæcum is not detected above the menhir?
- or the avæcum is detected above the menhir as in the whole region?

If so, should we use an artifice as indicated in [1] to choose one of the points of view? An artifice such as J. de la Foÿe envisages does not change anything.

This is where we see the importance of representation. In the example we have chosen:

- either we are interested in the menhir then we look at the close surroundings, then the place in which the menhir is located and this is what R. de Montercy and in an unconscious way P. Godart did.
- either we soak up the place and discover the menhir placed in this place; what J. Ravatin did afterwards, by transfer with three people present, C. Glaudel, G. Lhomme and R. Teichmann.

In this case, two representations are possible. The first, if adopted, allows us to affirm: there is no avæcum above the menhir. The second, if we adopt it, allows us to affirm: the avæcum is above the menhir as in the whole place.

We are therefore faced, no longer with a contradiction, but with two possibilities of expression depending on the representation <sup>14</sup> chosen.

For example, how does the vegetation near the menhir look like? Does she choose one representation over the other? Note that with a form-revealer one can, while remaining in one representation, detect what one finds in another. One can, if one does not find an avæcum above the menhir, by a revealing form, to detect some. Another form which would not be a revealing form, would allow while being in the second representation, to pass to the first (it would rather be a form which reveals an absence).

Vegetation or certain plants or herbs can play a revealing role, which means that we will detect on them what we find in a representation that is not the one we have chosen.

This experience lived with the avæcum and the conclusions drawn can be found with eifs. For example, an eif, the V'E is in the countryside. Will there be an underground stream? This will depend on the approach of the representation, by the detection of the eif. If we find V'E it may or may not be that stream. Naturally an underground watercourse is localized, but its existence still depends on the approach of a representation which can contain the previous one, be only a part of it or be another one.

<sup>14</sup> Representation does not necessarily mean change of C. of C. or in the other C. of C., change of R. of C.: Representation is the expression of becoming aware of the cerebral process that will take place in a timeline.

Let's see this in the following form: (The cerebral process, the awareness of the cerebral process; the way, the representation) has a halo: it is coherence in existence. The way is that expressed by the Tao. Representation is everything we choose to achieve coherence, in this whole there are the elements and their assembly. Afterwards, coherence appears, a coherence. We can give an image that will help to understand this concept: a child has a set of cubes and on each side of a cube is pasted an image.

The child must reconstitute a coherent image from the pieces of images which are on each side. In this example, there are six possible representations which will lead to six coherent images.

Let's look at another example <sup>15</sup>: a jet plane flying in a region of the sky where avæcum is detected; if we think of the plane in the sky, after having tested the region of the sky in which the plane will arrive, without thinking of the plane first, then we realize that the plane amplifies the avæcum around it except behind him where the avæcum is erased. This is a representation. On the other hand, we can think of the plane first and then test the region of the sky where it is located. Thinking it before the presence of the airplane, one finds avæcum, thinking it during, one no longer finds an avæcum behind the airplane; but in this case the avæcum is no longer detected, even after the plane has passed, whereas in the previous representation it was detected again after a certain time.

## Chapter XVI Silence

Silence: it is interesting to dwell on this concept because it is tacitly understood <sup>1</sup> in the everyday world but very quickly forgotten. On the other hand the poets often evoked it and in our approach the poets have great place.

We will often refer to a work by Max Picard: "The World of Silence" [1], and to do so quote a few passages.

In his introduction, Max Picard writes "Silence does not consist only in the fact that man ceases to speak. Silence is more simply a state in which man can put himself when it suits him". He points out, which is very important: "Certainly, it is not when speech ceases that silence begins. But it does not begin because speech ceases. It only manifests itself then". Is it underlying speech? Was the word hiding it? Is it like a form, her, on a background, him?

It is not in our language to consider silence as underlying speech, or speech erasing silence. If, on the other hand, speech is considered as projected onto the background silence, this can only be true in certain very specific cases. We will consider such a case later.

M. Picard ends his introduction with this: "One will perhaps be surprised that with speech one can articulate affirmations about silence. But we will only be surprised if we conceive of silence as a non-existent, as a nothingness. But silence is, it is a reality and speech can articulate affirmations about any reality.

And again, he clarifies what precedes by "Word and silence are one: the word is instructed by the silence as the silence of the word".

Should we deduce from this a dynamic duality between speech and silence? Before deciding, let's see Picard in a chapter he calls "Aspect of silence". "There is no beginning in silence nor an end...it is like uncreated existence". "It (silence) does not grow in time, but time grows in it. It seems that time has been sown like a seed in the silence, which it raises within itself; silence is like the ground where time is fulfilled"...

<sup>1</sup> In the sense of - content and accepted

We may be led to link the concepts of time and silence, which in the rational C. de C. does not make much sense, but in the other C. de C., it is the manipulation of concepts, even if these may seem totally foreign in the usual way, which is an effective construction tool.

Let us continue to skim over Picard's thoughts: "Existence and action are one in silence. It is as if the trajectory of a star were abruptly gathered up into a single light: thus are one in silence, existence and action".

Let's stop at this thought. Consider existence and action projected onto a background, in this case silence. At that moment existence and action become a macron. Thus Mr. Picard described it very well without knowing the concept of macron. What he says about it is of the same kind as the image given in [2] where we bring in a rider on his horse and the dust due to the horse's gallop on the dusty path which rises in volutes and we "integrate » the whole thing.

Let's come back to the concept: the delocalized, seen in volume 1 of [2]. The localized is existence with reference. There can be several types of location depending on whether we are in the usual C. of C. where there is only one or in the other C. of C. where there are as many as R .de C.. There are also very unstable localizations linked to islands of incoherence. We have therefore postulated the existence without landmarks which constitutes the global; that is to say the delocalized. The passage from the local to the global is made by an escape from landmarks, an ordered escape, by a decalar, an incoherent escape, by a channel. Thus from the localized, we were able to set up the delocalized.

The cerebral process which, of one has made it possible to postulate the second, is a certain course, a certain path:

localized ---Y-Qlê——> delocalized

Of a form F , thanks to this way, one could postulate Ext F . But the way, which makes it possible to pass from the localized to the global, can be rethought in the opposite direction, that is to say from the

.....

<sup>2</sup> Not every shape has an ext. On the other hand we can have different exts depending on what we do on F . Manipulations on F occur in the channel. This pathway is an unconscious cerebral process or even most often erased in the usual approach. The manipulations carried out on F, as mentioned above, for example drilling holes of small diameters, or putting lugs, etc., are the most obvious parts of the cerebral gait. The way contains that within it. In reality its plating after transport of structures (localized -> global) on F makes that we reach Ext F .

consider  $F \cup \text{Ext } F$ <sup>3</sup>. This constitutes an  $F'$  form. We are going to go from  $F'$  to what we are going to write and name  $\text{Int } F$ . Thus we will write:

$$\text{Int } F < \dots\dots\dots F'$$

We will have  $F$  which will be a part of  $\text{Int } F$  but  $\text{Int } F$  can be partly delocalized.

For example if  $F$  is the localized part of a human being,  $\text{Int } F$  will be this human being with his aura and what we see by the so-called Kirlian effect etc...

Back to the diagram:

$$\text{localized} \dashrightarrow Y\text{-}Q\hat{e} \longrightarrow \text{delocalized}$$

Let us apply to the noise which is localized this diagram:

noise  $\dots\dots Y\text{-}Q\hat{N} \dashrightarrow$ , > silence: silence is then the outside of noise.

Noise can be thought of as emerging from silence. Consider the reverse path:  $(\text{path})'$ <sup>1</sup>.

$$\text{localized} \longleftarrow (y\hat{s}\hat{i}\hat{e}) \longrightarrow \text{delocalized}$$

The  $\text{Int}$  noise will be speech.

Picard remarks: "...there is no longer any difference today between silence and speech. Silence is no longer a phenomenon for itself, silence today is only a word not yet uttered - in the same way there is no longer any difference between what has been acquired by research and what has not. summer".

And there he explains: "What has not been, what is veiled, is also no longer a phenomenon for itself, it is only what has not yet been acquired by research".

Let's study this paragraph. This is explained as follows:

$\text{Ext}$  (what has been acquired by research) = what is veiled!

As in the rational  $C. \text{ de } C.$  the concept of  $\text{ext}$  does not exist, what is veiled is reduced to what is not yet acquired by research<sup>4</sup>.

<sup>3</sup> The sign  $\cup$  is taken in the mathematical sense of the term, ie  $F$  and both  $\text{Ext } F$ , considered as a new form  $F'$ . ( $F$  and  $\text{Ext } F$  being 2 form-entities so that one has the union in the mathematical sense).

<sup>4</sup> Picard expresses very well the impoverishment of expression. Here, again, we realize the strength of the usual  $C. \text{ de } C.$ , its reassuring effect by its overly overwhelming logic, and the importance of putting in place the concepts belonging to the other  $C. \text{ de } C.$  to express coherences, that of poetry for example.

When Picard speaks of the difference between - what has been acquired by research and what has not been - this difference is due to the fact that the two expressions are not in the same C. de C. <sup>5</sup> or else they are both in the other C. of C. and in him there is a difference. This allows us to see that the other C. of C. is richer than the usual C. of C.; it contains subtle nuances. Picard does not conclude on the usefulness of today's science but he points out that "... there is no longer in today's science any real encounter between man and object" .

We have seen that the outer (which has not yet been acquired for research) is what is veiled! From the fact that this ext exists, we can deduce that man if he is faced with an object that he does not yet know or a new phenomenon for him, then:

the ext[(New object or phenomenon) U (what is veiled from the object or phenomenon)] = what we do not yet know about the new object or phenomenon.

But where does the Encounter between man and object take place? The Ext (what we don't know about the Object or the new phenomenon) = Meeting between Man and Object.

Silence, outside of noise, can be further deepened. To see this, let's go back to Picard: "...the cathedral...it is like the solid entrance to a well through which the silence descends into an even deeper silence..." and "...the silence of the cathedral which leads to the silence of the spirit".

"The cathedral... enormous reservoir of silence".

The silence of the cathedral behaves towards the silence of the spirit like the growth of the leaf [2]. We are faced with an AG <sup>6</sup> system [2] where we have the cathedral (Fi) and the silence of the cathedral (F2) <sup>7</sup>, the first the parent and the second the primer which are in equimsey. Let us consider a human being, that is to say the obs, who enters the cathedral.

The Voîloc de l'Obs is diluted in F2 and

$$(Fi \cup \text{the obs})|F'_2$$

Hence  $Fi | F2 = F$

$$(Fi \cup \text{the obs})|F'_2 = F'$$

S is the change of state from F to F'. Ext S is the silence of the mind.

<sup>5</sup> If the two expressions are in different C. de C., they are not comparable, and yet we speak of difference. This means that this "difference" can never be bridged.

<sup>6</sup> System AG = Primer-Progenitor.

<sup>7</sup> We will see later what must be expressed correctly.

Picard says: "The cathedral is like silence encrusted in stone".

The incrustation is a position of 2 bodies A and B, more generally of two forms A and B, which means that we can write:

Q

the cathedral (as an entity) is the halo of (the stone, A; silence, B) where A is encrusted by B . Consider the concepts of obverse and reverse of a coin. Are they in Dd? It depends on what you consider. From the moment we become attached to the shapes of a medal, we cannot speak of one without the other; this is not enough to put them in Dd But we can consider the obverse as emerging from the rest of the coin and the reverse likewise. But we don't have the obverse emerging from the reverse and vice versa. So we don't have a Dd Here the 2 faces are two inseparable limits of a fairly flat cylinder. If we consider the system as described thus: the obverse and the rest of the piece which we will name reverse, the reverse and the rest of the piece which we will name obverse, then we will have a Dd between obverse and reverse.

One can choose another representation of the obverse and the reverse: they can be considered in equimsey. They are then the emergence of a third delocalized term. Themselves are not necessarily localized completely.

Picard thinks that speech came out of silence and even better "out of the fullness of silence". "This plenitude would have exploded by itself if it had not been able to flow into speech". Let us first see what this fullness of silence corresponds to. This is the state that the Obs takes bathing in the atmosphere created by a T AG system: the Obs will project itself and silence into a T AG system, and the two will overlap; there emerges an atmosphere in which the Obs bathes. We see here that the Obs. does several things at the same time: it projects onto a T AG system of which it has the concept, places itself in one of the cells of this system, becomes impregnated with the atmosphere, it reveals itself 9 differently.

This is reminiscent of a decal type shape. To obtain a shape of the decal type <sup>10</sup>, one starts with a shape F, which is projected, soaked with a liquid or an atmosphere for example, and which is revealed afterwards, according to a shape F'.

<sup>8</sup> We write A embedded by B: A 0 B.

<sup>9</sup> This is one of the goals of initiation. Most of the initiations did not have a TAG-like gait for the brain. They were too little studied for that.

<sup>10</sup> Decal in Hebrew: H Sh hA Th - Th MWNW Th.

We have thus gone from F to F' and F' is said to be the transfer of F . The process followed is called the decal type process. We see here that diving into the cells of the T AG system is soaking up an atmosphere, that of the TAG system; we therefore have a decalco-type approach.

Picard affirms that silence is a primordial given. For him, man contains silence. Silence is related to the global as the exterior of noise. Man, when we speak of the entity man, this entity has an ext and an int, is embedded by silence (embedded as we saw previously).

And Picard presents aspects of silence. By succinct comparisons he renders impressions that one can have from silence. This succeeds because silence is both primer and progenitor. Silence is AG type. Picard writes: "In silence, man finds himself... face to face with the first beginning; everything can once again begin anew... At each instant, man can, through silence, find himself at the first beginning". Picard's approach is full of caution; his short sentences take you step by step, so the reader is gradually immersed in the depth of Mr. Picard's thought.

"Connected to silence, man participates not only in what is original in silence, but in all that is original. Silence is a primary phenomenon that is always available to man. There is no other primary phenomenon as present at every moment as silence is. It should not be deduced from this that silence is the only entity which is by itself of type AG. But silence encrusts man, so by this position of two forms Man and Silence (Silence 0 Man), Man is impregnated with the properties he feels in silence. It is said that silence is in itself an AG system whereas previously when we spoke of the silence of the cathedral, we had placed the cathedral as a parent and the silence as a starter. All this is not in contradiction. The progenitor cathedral is in equimsey with silence, {AG system}, primer. It is the silence in equimsey with the cathedral that is called the silence of the cathedral.

Picard thinks of silence as a primary phenomenon. For Picard, primary phenomenon: primary datum that cannot be reduced to anything. It (silence) cannot be replaced by anything else. Let us consider the set of primary phenomena: in this set Picard places love, fidelity, death, life. If we apply silence to this set considered as a background, we will have a halo: it will still be silence. Silence is its own halo, its own depth.

Silence is truly mysterious. The other primary phenomena, love, fidelity, death, life, are encrusted with silence. "There is more silence in them than outward manifestation" ... "there is in love, in fidelity, in death more silence than generally appears

of love, of fidelity, of death. There is also more silence in a man than he can use in his life. This is what makes any manifestation of man mysterious.

On the concepts developed in volumes 1-2 [2] and all those that have been implemented in [3] and [4], we can introduce those of evolution and transformation, even if the time is not present in this ocean of concepts.

For Picard, silence emerges from noise in today's world. He gives a movement to this emergence "... like something that goes back to the first times... silence... like a primitive animal... living "... and this emergence is done as if the animal hid by sinking deeper and deeper into the noise. It must be understood that this emergence in the noise (in our modern world, and this does not correspond to what silence was a long time ago) described by Picard presents itself as a presence immersing itself in the noise; there is no contradiction between emergence and immersion in this precise case because everything happens as if, little by little, the silence, from its primitive position, had moved and found itself present in an immersion. This silence of today carries with it the memory of the silence of yesteryear. It is always the silence of yesteryear, the only silence, it simply presents itself differently, but as it is its own halo, its emergence-immersion from noise is reflected on it and there appear two components of silence, the silence-primer, the parent-silence. This is why Picard writes, "You can still see the broad back of silence in the brushwood of noise". It seems that the silence is sinking deeper and deeper into the depth of its own silence); the depth of the silence is its aureolar which is itself, but the effect of the emergence of the noise which manifests itself in an immersion in a part of the noise, plays on the silence, AG system in itself. It therefore seems that the usual C. of C. acted on the silence by having destroyed its unity, then made two components appear, like those of the avæcum, where there was, if we take a representation, a sinusoidal component, colored red-orange, moving in translation, this is the component A, and the other dense, gray mass, this is the component G. \_

We also have (component A of the silence, component A avæcum; component G silence, component G avæcum) has an aureolar: it is the density <sup>11</sup> of the silence or of the avæcum. This density is such that Picard points out: "However, all the noise today seems to be nothing more than the buzzing of insects on the broad back of this animal of silence".

<sup>11</sup> But density linked to the notion of gravity (not fertilization or consequence of fertilization).

We have seen that we have used the concepts of evolution and transformation in the delocalized: transformation of silence as it was before, evolution by sinking into itself through the appearance of components A and G., the silence being the equimsey whereas before it was a unit. It would seem that the modern world has made it possible to make silence more explicit by becoming aware of its two components, of which the equimsey is itself. The rational world, if it is seen from the other C. of C. allows the obs, to move (by thought) to take relative positions of a C. of C. with respect to the other, to formulate what perhaps the Ancients had not attempted to establish, or perhaps superficially, or without being aware of it.

We have seen that Int noise = speech.

Picard points out "...that today the silence is diminished...". This is true if we stay in the usual C. of C.; which, moreover, erases any other point of view on silence. However, we have just seen that the use of the two C. de C. makes it possible to realize that this reduction gives rise to the obverse and the reverse of a coin. We have seen several possible interpretations of these concepts:

- they are described as emerging from each other.
- they are in DD
- they are in equimsey.

Picard writes "Speech, verso of silence, silence, verso of speech".

We can therefore construct

(Speech, silence; obverse, reverse).

This has a halo, but this halo will depend on the three possibilities above which give possible connections between obverse and reverse. There will be three possible halos:

- in the first case speech, image of silence and vice versa, but there is something between speech and silence; the halo will be: Dynamic Duality. The obverse and reverse are described as emergences.
- in the second case, speech and silence are in Dd; the halo will be the flow. Obverse and reverse are in Dd

<sup>12</sup> Picard adds "In every word, there is something silent that indicates where the word came from; in every silence there is something that speaks and indicates that speech is born from silence".

in the third case, speech and silence are equal; the halo will be: deployment. Obverse and reverse are in equimsey.

Silence is still this: it is the atmosphere of chaos.

Consider the notion of formless. It seems that the organized form emerges from the formless. In the organized form appears a coherence. Ravatin in these courses spoke of formless. The shapeless form is the form that is not organized.

Let's do (organized form, shapeless form; obverse, reverse).

This can have different halos depending on how the couple was considered [obverse, reverse]. Suppose this couple described according to the first case <sup>13</sup>.

The aureolar of: (organization, shapeless; obverse, reverse) is what has already been named the couple (emergence, immersion): which means that the preceding aureolar is the couple (emergence, immersion) applied to the form. In the couple (organized form, form-formless), let us retain for the moment only the second term: form-formless. Let us consider the form on the content, the shapeless and let us place the shape on the shapeless, we are going to have a halo: it is chaos.

Naturally one could continue to play and manufacture (form, chaos; obverse, reverse) by imposing the presence of the couple (obverse-reverse) and for example according to the first way in which this couple was envisaged <sup>14</sup>. There is a halo that we do not know.

One could have envisaged couples (obverse, reverse) according to the second and third ways, (organization, shapeless; obverse, reverse); we fall for the halos on concepts to which there corresponds no word, no expression in the French language.

Let us continue to study Picard's text step by step: "It is only when a man speaks to another man that the latter learns that speech no longer belongs to silence, but to man; it is through the *you* of the other that he learns it; it is only through *you* that speech belongs entirely to man and no longer to silence". Picard insists a lot on the *you*, which he has written in italics. The others are in the C. de C. de l'Obs.

<sup>13</sup> Note that we pass from the second case to the first by a flight, which is another way of approaching Dd.

<sup>14</sup> In the process (A, B; C, D) there is a pair which is in relative position; he imposes this position on the other couple and this gives the fifth term: the halo.

So when the Obs. receives the word spoken by another, he detaches it from silence. This happens when the obs places the others (who are in the echo of his C. of C.) as equivalent to him. At this moment it disturbs what we have put in place in all that precedes.

Let's project speech onto the silent background, we will have a halo of speech (what Picard calls the depth of speech); it is thought .

Picard, further on, considers speech to be born of silence. We must then consider the inverse process of form over content. Placing the form on the background is to make a trajectory of what is in the foreground on the background. Let us rather bring the substance over the form. In the case that interests us, we bring the silence background to the speech form; we are going to have a halo: here it will be language.

Picard says "Silence can exist without speech, but not speech without silence". It is not because we will have constructed the silence as the effect of the path on the noise that the silence is not primary. Simply by this process we construct concepts from the localized. These processes of obtaining concepts from the localized are more fundamental for the very first notions. To take a comparison in the usual C. de C., in mathematics, it is as if we gave ourselves the operators before the sets on which they act.

"Speech would be without depth if it lacked the background of silence", that is to say that the halo of speech in relation to silence, namely thought, is existence before being formulated as we present here. The formulation is necessary to put in place a formalism which will allow us to go much further. So we build a world of concepts. When it is sufficiently important, it takes on a new character, it is a primordial existence, even more, it is an existence "before Creation" to use the expression that Picard applies to silence without speech "The silence without speech is of the order of what precedes Creation, it is unfinished Creation... It is only by the fact that speech is born of silence (we have seen what should be understood by this expression), that silence passes from what precedes Creation, into Creation, from what is not historical, into the history of man, into his proximity; it becomes part of man and a legitimate part of speech...". This world of concepts as it grows, takes place as an existence. This confirms, what we had already hinted in [2], that our approach must be dynamic and not static as when evolving in rational C. de C.. /Thus the establishment of this world of concepts is to the domain that one approaches, what silence is to Creation (world of concepts, domain that one approaches; silence, Creation) has a halo: the world possibilities.

Next Picard "Possibilities that are not realized are food for silence; through them, silence acquires more strength and, in turn, becomes powerful nourishment for all that is realized otherwise".

We will not say that these possibilities will never come true, however we can bet the existence of such possibilities but they are strange. Is there a R. de C. where they could be realized, or even an island of incoherence?

Then can we only speak of this set (if it can be a set) of possibilities which are not realized in islands of incoherence? Because we are aware of this "together" we can build something else by taking into account these possibilities of which we are aware and which do not materialize (this explained outside of a duration) then of those which we do not is unaware and of which we think the existence. They are going to be incrustations on the silence, which means that even if we made the silence disappear, they would remain. In some of these possibilities that are not, there is incoherence, which means that we must remain cautious in approaching silence.

The R. de C. are diluted in silence, even islands of incoherence. The set of wandering points which move on the straight lines of the diagram given in [2] and [3] constitutes the biblical chaos.

We will immediately see a new type of shapes: diluted shapes. They are not representable, they exist as contained in a form which in general is delocalized. For example, consider a two-dimensional network, with square meshes, or parallelograms or others. A UFO, as long as it is not partially located, is a diluted form in such a network; there will be several types. This network is an incrustation in the usual C. of C.. One can have a form of an island of incoherence, which is diluted in a network-incrustation and which can be localized (partially) <sup>15</sup>. A network is associated with the human being - it is on a surface, that's what we named in the voiloc [2] and [3]. The equimsey of the form on a background, this gives the functionality. If they are localized, it is generally an OT If some are delocalized, it is an OP

<sup>15</sup> Forms are diluted into networks. From the networks, forms can emerge if they are solicited by something else.

By imposing these features, we often localize . This will cause that between T and U <sup>16</sup> there will be a transfer, or a collapse, finally a new entity more or less localized and more or less stable TU can form, we could even have a halo

(T.U; O.O).

But we can still have the schema where U does not yet exist but where we have:

-----©

©

The following phenomenon occurs: T evolves according to a story, either a U is created directly and then we can fall back into the previous pattern

>  
U

Naturally for people in favor of the ternary they would see one in

features

shape                      background

But making ternaries does not look like much, especially when the 3 terms are not equivalent.

Consider a form T or a system T. Consider a non-localized concept (T) such that we have

T < -----Q

where the arrow can mean the reverse route .....> or a projection or another concept.

Let us give U similarly in gender to T and Q similarly in gender to Q. A © and Q can be associated with states, for example. But it may be that between U and Q there is no connection. Between @

<sup>16</sup> Where T and U are OT or SV for example, and 0 is the ext of the OT T with its functionalities, or the ext of the SVT with a background, the possibilities are multiple.

and O can occur a Dd, an equimsey, a projection of one onto the other, a detection of one in the other, overlapped by the other, etc... Thus we will have a schema like

-----©

**u4** -----©

“UFOs” can come from overlocalizations due to the multiplication of OTs. Localized features become overlocalized. The OT thus projects itself onto the background which is a neighborhood in which it is located. At that moment, this background and this OT are diluted in a network which is an incrustation of the local. This overlocalization of functionalities leads to the creation of states like |K Sh Ph> with reversed Shin and even with other characteristics.

We can also have effects on the SV <sup>17</sup>. Very localized functionalities can create states of the type |K Sh Ph> because, for example, the OT can stick to the bottom. The OT ext and the functionalities go into |K Sh Ph> state.

Thus can occur a process that will be reduced to the following diagram:

and creation of a new system

/SV\

\O/T/

The background which only exists because there is the shape (the background changes as the shape is developed) is made up of leaves. Consider an OT. The OT dislocates these

<sup>17</sup> VS: Living Systems.

We recall OT: technical objects OP: Phenist objects.

sheets and brings them to collapse, we then have a magfeu [2]. The magfeu is diluted in our physical universe, so an island of incoherence can come out of it, the trace of which in the usual C. de C. is a UFO. But of course all this is only one possibility among many others. The OT may not have an ext (a steam locomotive considered as all of its parts has no ext; the same for an electric locomotive. If the steam locomotive is considered as a whole, it has a slight beginning of ext). The ext can come from a set of OT, or from a neighborhood of this OT or from the coherence in which the obs places 1'0.T. To carry out an OT is to provoke an emergence. On certain backgrounds, the OT can project itself and give a macron OT ' time , [2].

The bottom can also come on the OT. If Q is a reference leak as we saw in [2], the following case may arise: As in the case of the Basque pelota game presented in volume 1 of [2], we have two scales.

Between Q, the mac  $\left( \begin{matrix} \text{O.T.} \\ \text{S.V.} \end{matrix} \right)_t$ , the background and the two scales, a network is created, the of the UFO is an emergence of certain nodes of the network.

Here for this attempt to explain the UFO phenomenon, we did not involve the polaror as in [2]. This attempt can replace or complete that of volume 1 of [2]. It is also fundamental to refer to [4].

“If you cross the Halys, a great empire will crumble”

Oracle's response to Croesus

## Chapter XVII

### GNOSTIC DOCTORS AND THEIR SYSTEMS

This text is put in complement for the comprehension of works of L. Boutard and A. Hatinguais, but the presentation is made to attach a little to the mode of expression and the representation of the occultists. According to Simon of Samaria, at the summit of entities, that of fire, infinite power of all the aethers and states of heat. This power to act goes into action. To express its thought, intelligence named it, and having named it, it was able to unite its different ideas and form a whole. From this all were drawn six beings or emanations of infinite power. These beings were obtained by syzygies: two by two active principle, passive principle. Simon also had the six aeons of the superior.

- |   |                      |   |                         |
|---|----------------------|---|-------------------------|
| + | We (mind)            | - | Epinola (thought)       |
| + | Phone (the voice)    | - | Anoma (the name)        |
| + | Lagismos (reasoning) | - | Enthumesis (reflection) |

In each of these six aeons or primitive beings (nixais), the infinite power was found entirely in “potency” but not in “act”. To pass into “act”, one must make an appeal to an image which is in conformity with what one expects from the infinite power by an “image”. For this, the aeons themselves became principles of emanation and six intermediary aeons were created. Finally in the terrestrial world took place the material creation itself according to the law of the similarities which says that all the beings of a particular world develop in a way in conformity with that in which developed the higher world and that all the beings in each world are themselves eager to instigate what their superiors in the emanation hierarchy are doing. The desire carried out leads to the principle of the fall.

Energetically, the principle of Gnostic generation is always the same: the active power enters into communication with the passive power, deposits therein a germ which is only a spark; the germ grows and develops according to image and likeness. The doctrine of Basilides of Egypt completes that of Simon. At the top, the god who is not, the nothingness that exists “o co x ontheos” (which can become something), passes through internal action in the God called Giotés, of triple essence and triple activity; under its action, there is a first emission (Katabolé) which is, which becomes the act.

The first rises to the pleroma; the second (carried on the wings of the Holy Spirit) only reaches its limits; the third remains in the germ of the world: for it redemption is necessary. Thus the upper world is created. The intermediate world was then created by the union of this germ of the world and the treasure of all the seeds: the great Arkôn was born enthroned following the superior world. The basis of God's nature is Love, and Love cannot do without an object to love. This zArkôn generates a son. The link where these mysteries were realized is the agdoade which extends to the moon where reside the principalities (Archai), the powers (Dunameis), the dominations (Exausiaï) and three hundred and sixty five gods governed by the great Abrasax (corruption of the great Hebrew blessing (the Barecha (from Berech: to bless)). Abrasax can be given either the etymology: Al Braxas (the blessing stone), or "abra-q-ad-habra" (meaning: "Send your lightning until death"). From this world of the Ogdoad emanates a whole other world which reproduces the first according to the principle of similarity. There was thus a second Arkôn dominating the space where we live; where the potentiality of all the possible germs is. But the beings emanating from a world cannot conceive of a world better than their own. The second Arkôn was unaware of the first and wanted to dominate in turn the geniuses. These resisted him and it was a terrible struggle.

Valentine of Alexandria humanized the teachings of various Gnostic schools. Emanation is the basis of his system. In the intermediate world the Prince is the "Demiurge", "The Ancient of Days". The material essence has another prince: Diabolos; the spiritual essence has as its prince Beelzebub; the Demiurge is stupid and "coarse"; while the divine wisdom Sophia acted and created, the Demiurge believed that everything came from his hands and imagined himself to be God.

Valentine definitively establishes the Gnostic science of the pantacles; destiny therefore depends on the powers that preside over acts; as for the acts themselves, they have no influence, they only indicate the strength of the dominating powers. For Valentine seven planets enter the twelve signs of the zodiac; the rising of these planets is directed by the powers. They indicate the movement of matter. There is often a struggle between the powers.

In gnostic pantacular science, in addition to the "name" (the name is the thing), source of the power of the pantacle, appear the respective representations of the god, the angel, the daimon evoked as well as the symbolism of planetary time.

The Gnostics modified what seemed to be uses and brought very precise, new and important operative elements. Tables were set up in a way that seemed strange by the proximity of the names: Yahvé, Adon, Sabaoth, Michel, Osiris, Isis, Anubis...

The DLXXIV papyri from the National Library - Mimaut 2319 from the Louvre, the Gnostic demotic papyrus from Leyden, the Greek papyrus XLVI from the British Museum... show this work of synthesis on the problem of the psalmodation of "energies". The Cabinet of Antiquities of the National Library contains a large number of Gnostic amulets including the ABRAXAS, which according to the Greek numeration system gives:

A = 1

B=2

R=100

A= 1

S=200

A= 1

X = 60 for a total of 365

These considerations are profane; they circulated among the people. They are not initiatory. Gnostics wore abraxas and according to their rank they had to be able to explain to which device was related such or such abraxa except some which were known only to higher grade gnostics. Gnostics have related it to Mithras whose Greek name meitras has the same number.

M=40, E=5, I=10, T=9, R=100, A=1, S=200.

The Abbé de Montfaucon divides the abraxas into seven classes:

- 1) Those with the head of a rooster
- 2) Those with the lion's head
- 3) Those at the head of aévanis
- 4) Those with the heads of Anubis, snail, Sphinx, snake, monkey
- 5) Those with human heads with or without wings
- 6) Those with Hebrew inscription
- 7) Others more bizarre.

The divine nomen (definition of what is to come) is known as Abraxas for Abrasan,

3 \_ \_

substitution which is explained in the Latin scribes of S and CZJ. Subsequently, the use of the name

angelic par excellence gave the general name of the Gnostic stones found. The name of Abraxas was associated with figures of which the most frequent was Anubis carrying

The inscription of Miletus in Asia Minor, published by Le Bois in 1847, gives the correspondence between all the Greek vowels and an “energetic” sphere of action linked to seven planets, satellite (the moon) and star (sun). The planets were:

Saturn  
Jupiter  
Mars  
Sun  
Venus  
Mercury  
Moon

The 2nd century Gnostic musicographer Nicomachus of Gerasius says: "The sounds of each of the 7 spheres produce a certain noise, the first realizing the first sound, and to these sounds have been given the name of vowels...The Theurgists invoke the divine by snapping lips, hissing, inarticulate sounds without consonant. It is the cerebral configuration of the human being which creates the relationship between the sun, the moon and 5 planets and the sounds. The human being, through his thought, arranges the correspondences in a given representation.

The seven-stringed Greek lyre (heptachord) is quoted in the Leyden papyrus W and in the "Papyrus Mimaut"<sup>18 19</sup> One establishes the correlation by psalmody of seven vowels with seven virtues or powers.

<sup>18</sup> Published by C. Leeman, Papiri

<sup>19</sup> 9319 from the Louvre.

Seven metallic principles preside over it with 4x7 moonlights in seven intonation sounds. The Gnostic incantatory formula will be:

Pronouncing towards the West, the right hand extended towards the left and likewise the left towards what is on the left, you will say A; towards the North, the extended right fist, of the say E; extending both hands towards the south of the say H; then towards the south, the hands turned towards the stomach, you will say I; spitting on the ground and touching the extremities of the feet, you will say O; looking up, hand on heart, you will say y; looking at the sky and with both hands on your head, you will say Q.

The magical papyri that have come down to us indicate a constant use of Greek vowels both as vocal notation and as sacred syllables, but also as an "energetic" indication.

Note : It would be hasty to identify Boutard's atoms with the atomic nucleus and electricities with the electron cloud; one cannot reasonably confuse the process of arrangement of the small snakes with that of the shells of electrons N, O, P, Q; moreover for iron and copper, we only have the N layer.

All one can do, if one follows the Gnostic theory, is to note that the world of matter (of the fall) is the imitation of a process of which only prototype matter is the primary form (arkon ).

Amplifying generator : While the truck represents the element fundamental of the automatic generator, the crescent of steel is that of the

une dont les collecteurs sont des fils de plomb (bleu noir), une dont les collecteurs sont des fils de cuivre (rouge).

The sausage is rolled up on the wooden mandrel. The nature of the wood of the mandrel is not specified.

The conductor of the inductor current consists of a strong insulated copper wire which, after having been wound on the head, enters the cap through an opening provided for this purpose to receive the coil already wound as well as ...

Outputs are provided for lead, brass and copper wires.

All of the above 4 strips are wound on the cylindrical part of the wooden mandrel showing a mushroom. The base of the cylinder is terminated by a cone. The set is about 25 cm high.

The choice of wood is important. The height is not.

In L. Boutard devices: metals used:

|                 |                                       |

attract the outgoing Aether if the  
iron is shiny and polished

Loving the Aether

Copper collects red atoms

Brass collects yellow atoms

Lead collects blue-black atoms

Mercury promotes the disintegration of the Aether by attracting the blue-black atom.

The goal used for Boutard is to dissociate the Aether and to draw from it the elements from which one expects an energy by collecting the male atoms and the female electricities, using appropriate

## Chapter XVIII

### Complement on the use of some projective geometries

We are interested in finite order projective geometries. We refer the reader to the numerous books and articles relating to these subjects. Ravatin noticed that if we detected avæcum around the shape given by the chosen representation of the projective plane, it did not depend on the representation. The representations are made in an ordinary plane but the lines have only a finite number of points.

Example: the plan of order  $k = 2$ . It has  $2^2 + k + 1 = 7$  points and 7 lines. For each point it passes  $k + 1 = 3$  lines. Each line is made up of  $k + 1 = 3$  points. Here we have a possible representation.

<sup>21</sup> For eifs, it may be different. The term representation is taken in the sense of a figure drawn in a plan.

Other representation:

: To determine the eifs, it is necessary to make the lines by metal wire or even string, and the points are hollow spheres. This projective plane of order 2 thus produced emits a very strong avæcum. He has an ex. There is a way to use pieces of projective planes only by perforated plates: part of the representation is on one plate, the other on the other plate. The two

For example, with such an assembly, starting from the projective plane given in the preceding example, any form is transformed into a perfectly stable emitter of avæcum.

You can use several projective planes either represented by hollow spheres and wires, or holes drilled on the plates, or you can add engraved lines to these plates.

By having projective planes of order higher than 2, we have interesting properties when points belong to the same conic or the same oval. Similarly there is no interest in looking at the points and lines which correspond by translation, reflection, dilation.

Moreover, configurations like that of Desargues are to be sought in certain cases. Of <sup>22</sup> constellations can be thought of as parts of projective planes. A transfer is then established between the constellation and one or more projective planes.

Plans of order 2, 4, of order 9 are interesting. Plans of order 15 are even more interesting. Their realization and study are very delicate.

The projective planes of order 15 or 16 are linked to the psyche of the human being [2].

<sup>22</sup> The constellations which are to be considered are those of the Ancients. On the other hand, we must pay attention to the fact that certain constellations of the ancients have been transformed: example: that of the "Vessel" which has been separated into three:

The Hull - The Stern - The Sails.

The Ship is attached to the Nave of the Argonauts. It is therefore necessary to work with the Vessel and not one of the three

Stern

These diagrams are taken from the Illustrated Atlas. Constellations by J. Klepesta and A. Rükl, Edit. Gründ, Paris (1968).
