Conclusion

Pietro Zampa, a master

Dowsing in Italy is linked to a name: that of Eng. Pietro Zampa. Who knew him before the war remembers a physiognomy that made one think of the great altitudes and had the placid majesty of it: the whiteness of the snows and the blue of the sky. That blue that was in his eyes flashed just at times under the thick eyebrows when the fine and good-natured smile appeared shaded by the white moustache on which the nose curved between the still florid cheeks. Noble and imposing in bearing, he had the sly tranquillity of the philosopher who listens and meditates and whose witty phrases suddenly amaze you, and he was so profound a philosopher that he thought he hated philosophy; because he understood the great things that are clear only to the simple and escape the complicated and abstruse minds. His judgment was always upright and clear, and inspired by the highest spirituality, for he was a sincere believer and kept his eyes fixed on the eternal. Like all the pure in heart, he had a chosen mind and the soul of a child: in life he was naive and therefore he was never fortunate, of the fortune sought by the greedy and the ambitious: his fortune was not of this earth, it awaited him in the hereafter. Life took everything from him before it gave him death; or rather he gave everything to life. When I saw him, the dear Master and friend, for the last time in August '42 in Miramare di

Rimini, in a little garden not far from that beach that the war was about to upset with iron and fire, and that at that time was still populated by colourful and playful bathers, he had already given all his vitality to work, study and adverse fate. In the last refuge of his existence, from which he would not have been able to escape at the approach of the horrendous bloody storm that he (a valiant fighter in the war of 1915) detested with his deep humanitarian sense, Pietro Zampa was almost nailed on an armchair by his unsteady legs and could not recognize me except in the voice that greeted him moved, because his eyes already full of light could not see anymore. The lonely soul still shone in him with the hope of the future beyond the future. And he was comforted by the devoted and unalterable affection and assiduous care of his soul mate. Then his dear and noble figure disappeared into the darkness of events, cut off by that insurmountable barrier of armed men that for months and months divided Italy in two. I no longer received even his letters that another hand wrote for him, faithfully reproducing his thoughts. Afterwards I searched for news of him in every way and finally I was able to get it, but not from him, because he was no longer there. In July '44, while he was dying, the streets around him were sprayed with deadly volleys and not even the doctor could reach his bedside. He, thus, calm and serene left the earth amidst the roar of the most frightening storm, yearning for boundless serenity.

He was born in Bologna in 1877; he descended from a noble family from Forlì which included, in addition to his father, a famous doctor, other illustrious members, such as the Napoleonic general Giovanni Zampa and Count Carlo Matteucci, a distinguished physicist; but his talent was particularly versatile, ranging from technology to art with surprising ease. After graduating in engineering in Italy, he lived and worked abroad and in 1918 he was called to direct a large industrial plant in Milan. He designed and directed the laying of underground telephone cables in Liguria and Tuscany and in part those of the national network in Calabria and Sicily with the relative laying of submarine cables. He had a great passion for agriculture and in 1896 he was the first to introduce the use of Sack ploughs and chemical fertilisers in Umbria; he then advocated the large-scale cultivation of soya and sugar sorghum. In 1920 he was the first to compress

methane gas into cylinders to power internal combustion engines. His technical writings are numerous and document his knowledge and prodigious activity in these fields. A fertile and brilliant musician and man of letters, he expressed his soul in wide-ranging operas, of which he also conceived and wrote the plots and librettos, preferring classical forms and drawing inspiration, while maintaining a personal originality, from his highest artistic ideal embodied in the sublime genius of Verdi, for whom he had a deep veneration. His musical studies had been perfected under the guidance of the great Maestro Giulio Massenet. Of Pietro Zampa's nine operas, some have been performed in important Italian theatres with flattering success. But what particularly interests the scientific environment of our readers is that Pietro Zampa was the first to introduce Radiesthesia in Italy. His mind, open to all possibilities, had grasped the occult essence of this apparently magical science, founded on the physical reality of the universe vibrating with intense life, radiating infinite energies in an incessant exchange of communications from star to star, from atom to atom, from psyche to psyche. He understood that grandiose phenomenon which leans its manifestations on the most refined human sensibility, for the reception of the irradiations of the bodies and of the vibrations of the thought, and launched the first word on which the Italian Radiesthesia is building its solid scientific basis. This is the best proof of the faculty of intuition of Pietro Zampa, in whose hand the pendulum swung and turned speaking a clear and precise language, which translated into nods on the dials he devised the unknown realities and revealed to him the secrets of the brain no less than those of the subsoil. His volume "Elements of Radiesthesia" has taught and teaches to all the wonders of this science; his other book "Radiesthesia in Psychical Investigations" presents the way of measuring and evaluating the intelligence, mental aptitudes, qualities and defects of human beings. And his dowsing novels: "The Treasure of the Rocca-bruna" and "Atonement" are two typical literary jewels full of fine humour and dramatic sense at the same time, illustrating the advantages of the application of Dowsing to practical life. All these works are published by the Vannini Publishing Company, which had also entrusted him with the direction of its Dowsing Library. In the world everything passes and everything is renewed, but the truths remain incorruptible and eternal. Pietro Zampa had found a truth, believed in a truth. This truth we also, by studying and experimenting, seek and love with him, even now that he is no

longer here. Continuing his work we pay homage to him who was our dear and unforgettable Master.

Preface

One day (since then several years have passed) a noble and learned French lady, who had just returned from a journey to her native country, showed me a sort of pendant attached to a string, and asked me: "Do you know this?" I blushed at my ignorance, and had to confess, that I was not at all acquainted with the pretty trinket, which she continued to dangle before my eyes, and that I had no idea what it might be. Well," she said, "this trinket is a magical, wondrous thing, because it can answer in the affirmative or negative to all the questions you wish to ask it. And as I looked astonished at my kind interlocutor, not knowing whether she was being serious or mocking me (which she does with such grace and sparkling vivacity, all Parisian) she grabbed my right hand and on the back of it suspended her pendant by the thread that held it. And I saw the pendant, without any thrust being impressed upon it, move spontaneously and begin to swing along the longitudinal axis of my hand. Then the young lady in turn extended her right hand and gave me the pendulum to hold, which, this time, began to turn whirling on the back of her hand. I stood speechless. "And that is nothing;" she went on to say, "it is nothing at all compared with what this pendulum can say and do. I don't know how old you are, but I can tell you at once. And in fact, after having written on a large sheet of paper a beautiful series of numbers, from 40 upwards, lightly touching my right hand with his left, he began to hold the famous pendant suspended with his right hand, first on 40, then on 41, then on 42, and so on until 58.

"You are, then, fifty-eight years old," she said to me, and I, not being a woman, nor having any reason to conceal my age, had to say, "It is true."
"But you are something more than fifty-eight; there must be a fraction of a

vintage to add: the pendulum tells me so. Let me see if I can guess again." And he wrote, on another sheet of paper, from 1 to 12, that is, the months of the year; and repeated the operation of before. Now I was born at the beginning of December and we were, at the time of this experiment, in April, therefore 4 months to add to my 58 years. And the pendulum, which had always reacted negatively on 1, 2 and 3, began to turn when it was above 4.

"Do you wish to know also the number of weeks, of days, of hours?" continued the amiable young lady to ask me. "No, no, that's enough for me; that's enough for me!"

I was, more than astonished, stunned. Why and how that trinket now swung and now spun I could not understand. Magic? Spiritism? Mediumship?... Yes, I confess it; at first I believed that the pendulum obeyed to some occult force; later on, studying in depth this phenomenon on authoritative texts of eminent scientists and pious priests, I found the explanation of many facts that in the first times were shrouded in mystery. But from that day on, when I returned home, I immediately began to make myself a trinket to serve as a pendulum, and I applied myself to making trial after trial, experiment after experiment. Unfortunately - I recognized it later - I lacked the basis for obtaining good results. I considered, in those first times, the pendulum as a simple toy, ignoring its prodigious possibilities, and the immense vastness of the new and almost unknown science that gravitated around it! If I guessed anything by means of it, I acknowledge that it was by mere combination, or because, unconsciously, I had operated according to the rules of art. I was, in short, in the same condition as a child who has a good piano before him. He does not know how to play it; but it may be, that when he lays his little fingers on the keyboard, he will draw from it a beautiful consonant chord; but to make pleasant sounds, beautiful melodies, to make him sing, in a word, it is necessary for the child to study for several years, not only the piano, but solfeggio and harmony. After a few months that I was swinging and turning my pendulum, the first Treatise on Dowsing I read came to my hand: the beautiful one by René Lacroix à-

l'Henri. It was a real revelation for me; it was as if God had given me a new visual power that allowed me to explore, with my glances, distant regions that dense clouds kept hidden from me. I saw unknown countries, astral worlds that my mind had never conceived of. And then I was invaded by the eagerness to know more and by the ardour of research. A very good friend of mine came to help me by providing me with a number of foreign publications which illustrated diffusely and with richness of data and theories, all this great scientific problem of Radiesthesia. And the more I studied it and the more I experimented it, the more I was aroused in me the wonder and the admiration for this science which, through the cosmic waves and the vibrations of the bodies and of the ether, puts us, almost, in direct communication with the Creator of the Universe. So, continuing to study, and comforted in this by my dear and learned friends Dr. Aldo Buttazzoni and Dr. Valerio Perchiazzi who so much enlightened me with their advice, I thought to collect in this booklet what I had learned from others and from my modest personal experience so that it could arouse, in scholars, that curiosity that drives us to be interested in something and then to devote time and talent. I know very well that I will have to fight against the scepticism of the ignorant and of the supermen. I know this ridiculous skepticism, this spirit of denial of which many people are so proud, but I do not fear it. How many times, speaking of the virtues of the pendulum, have I seen myself laughing and heard myself say: "Are you dreaming or do you want us to understand? It's all nonsense! etc. etc.". Of course, I do not even discuss with such people, because their blunt denial is the best proof of their gross ignorance. You cannot reason with ignorant people or with deniers for their own sake. The man of true intelligence and rich in doctrine will never deny a priori a fact or a phenomenon that he ignores, even if he does not know how to give an explanation immediately because he who has studied a lot has learned a dogmatic truth, fundamental: that nothing, or almost nothing, we know of what the Universe encloses in its infinite kingdom. It is not, therefore, for those who do not know how to do anything else but deny (because their brains are very small) that I undertook the fatigue of exposing in these pages the elementary principles of Dowsing; but if such fatigue I made it is in the hope to make proselytes and to spread also in Italy an art that in the other Nations is already flourishing and that counts so large a crowd of adherents. Radiesthesia, in fact, which can be considered an art, as well as a science, is strictly called to exert a great influence in the

civil world and on its destinies because it allows us to know the mysteries hidden in our planet, as well as it allows us to put us in direct communication with each other with the only thought and without moving, crossing the oceans with our radiations, flying over the highest mountains with our vibrations. I have had to adopt in this writing words which are certainly not to be found in our dictionaries, at least in the sense intended here. For example, pendulum, wand, prospecting, etc., but I have not yet found the equivalent terms. But I have not yet found the equivalent terms and I leave to others the care of this linguistic study. On the other hand, it is not always possible to substitute one word for another, especially in the technical or commercial field. I do not know what reception the public will give to this modest work of mine, written without great pretensions, but with the sole purpose of making known a new branch of study that will bear good fruit, in due time. I have tried to be clear and concise because I wanted to make, in these pages, a general picture of the matter, to offer an overall view of it, because Radiesthesia, as it will be seen, embraces many fields of human activity: from the research of waters to that of minerals; from police investigations to medicine, and so on. But everyone who finds here a starting point for his own specialized branch of study will be able, later on, to consult the distinguished works of the masters of this science and to deepen, in this way, his own knowledge on the subject. I do not know whether in so doing I have been a good sower: and whether I have sown the chosen seed well. I have put all the effort and all the love I felt animated by it, hoping that my readers may, one day, reap happily and profitably the rich harvest that will sprout from it.

ING. PIETRO ZAMPA

Part One

Chapter I

What is dowsing

It would be, perhaps, more appropriate to give the definition of this word, of rather recent birth, at the end of the present paper, instead of at its beginning, so that the reader, who had the goodness and the patience to read it all, could grasp its fundamental concept, discarding, with a certain knowledge of the cause, the idea that Radiesthesia is part of the occult sciences, of spiritualism, or is, maybe, some art, some emanation of the Angel of Darkness. But since Treatise or Manual, more or less scientific or didactic, must, according to the ancient customs, define, in primis et ante omnia, the subject of which it speaks (almost to make it decline its own generalities) I will try to explain what is meant by such word. Radiesthesia is the science which, by means of the capture of the irradiations that every body or every substance emits, allows us to discover hidden bodies or substances, to know the location, the entity, the nature, the species and the quality, and the influence that they exert one on the other. It will be said to me, that this is nonsense or utopianism. But before pronouncing such a grave sentence, without any positive foundation, have the courtesy, my friend the reader, to read this little volume, which I have endeavoured to make as brief as possible, and as rich in facts and data, in order to present it to you in the easiest and most agreeable form. Read it all and meditate well on what you will read. Remember that the truly wise, intelligent, and learned man must never deny anything a priori, nor must he admit anything without proof or without knowledge of the facts. What we call Science, that is, our cognition of earthly and otherworldly things, is as vast, as infinite as space. What we know, or think we know, is nothing, scarcely an atom, of the great mysteries of creation, some of which we glimpse, some of which we know; but the greatest part of the remainder will perhaps remain unknown to us for ever, because they belong only to the Divinity. And if the Most High allows Humanity, through some Genius, to snatch from Nature some of its immense resources, some of its countless treasures, not for this reason He reveals to us the nature, the origin, the secret. We have an example of this in electricity. Today we use it at our pleasure for lighting, for heating, as a motive force, as a means of healing, etc., etc. But do we know exactly what it is? The definitions we try to give it are vague,

uncertain, and perhaps erroneous. Therefore, even this new science, which presents itself to us so shrouded in mysterious unknowns and dense veils, must be cultivated and spread because the benefits that humanity will be able to draw from it are endless, in every field of our activity, as I will demonstrate later. Do not laugh or scoff, dear reader, at what I am going to expound to you in these pages. Only fools, ignorant and presumptuous people think it their duty to deny what they do not know or what their short minds cannot understand. When I spoke earlier about irradiations, some may have wondered what I meant by this word. Irradiations are emanations imperceptible, directly, by our five senses, which are released from any animal, vegetable or mineral body, and which spread through the atmosphere in much the same way as sound waves, supported (I would say almost) by electrical waves, which spread through the ether and go, free and mysterious, from one point to another of our planet and perhaps, beyond. Such radiations, as I have said, are not perceptible by our material senses, except in some individuals who can pick them up and feel them directly in different ways. However, almost all normal people can grasp them, understand them, interpret them, more or less powerfully, and even make use of them, by means of small and very simple devices that act for us almost as radio-antennas. In fact, we, with our marvellous, complicated and still unknown human organism, are nothing but an extraordinary and very perfect receiver of light, sounds, smells, colours and other infinite sensations, not only material but also spiritual, which for the most part we do not even feel because we ignore them, because we neglect them and because we do not think about them. Until a few years ago the word Dowsing was absolutely and universally unknown: so much so that we do not find it registered either in vocabularies or in the major modern European encyclopaedias. Today, however, it begins to make its entrance, resolute and triumphant, in the world of intellectuals and of those who, greedy of knowledge, are always looking for the new and the true. And not only does it appear, now, quite frequently in foreign newspapers and magazines, whether of a political, literary, scientific or religious nature; but, in its name, congresses are held, conferences are held and Associations are formed among the lovers of this new science which already has to its credit a discrete collection of publications that speak about it at length with profound and meditated knowledge. But it is not enough: in England Radiesthesia is officially taught in the Military Engineer School. In

Germany there are already more than 12.000 dowzers gathered in a large national Association. Similar Associations are also found in Belgium, Switzerland and especially in France where almost every province has its own Circle. All those Circles are headed by the big society called "Association des Amis de la Radiesthésie", founded in 1931 and based in Paris, Boulevard Magenta, 105. In Italy in this field we are still very backward and Radiesthesia is still almost unknown both in name and in fact. There are some people who use the hairpin (dowzers) and other very few use also the pendulum; but both of them use these means almost only for the search of water, empirically and without knowing or being able to draw a real profit, completely ignoring the most elementary principles of this singular science. Certainly there will be some who, in the face of this solemn word science, will shrug their shoulders and tell me that it cannot be called such a practice that is not based on any scientific fact and that does not yet possess (how should I say?) a birth certificate, a marriage certificate or a civil status. But what do you mean by scientific fact? The scholastics or the big wigs will answer me that "the scientific fact is the one that can be reproduced by anyone, anywhere and always". Big mistake! There is no scientific fact that can respond to such a concept, for it is absurd to believe or think that anyone can do anything in the scientific field: discoveries, inventions, etc., which are reserved only for a few men enlightened from Above and which are not born every day. It will be said again that Radiesthesia does not have a civil status; that it is not officially recognized as a science, etc., etc. Well, is this sufficient to deny it its place in the wide arena of human knowledge? It is evident that, in order to be admitted into the Scientific Senate, every manifestation of genius and doctrine must undergo its apprenticeship; it must present its documents, its certificates; it must produce its proofs, experiments, etc.; but, in order to possess all this enormous wealth of knowledge, it must be able to produce its own results. But to possess all this enormous baggage of academic garments takes years and years. You will tell me that Radiesthesia, even if you want to consider it as a science, is not yet perfected. It can be, indeed I admit it certainly. But what do you mean by this fine tuning? Is it the tuning of a violin or a piano? Is it the tuning of an engine? No. So what? Tuning means the attainment of perfection, the complete development of an art, of a theory, of a science. But what science in this case is fine-tuning? None, since every day a new fact intervenes which shows us that what we believed to be unsurpassable

yesterday has already waned today. Science is not an art like music, like painting, sculpture and architecture, which have already reached the now unattainable heights of perfection through the work of geniuses such as Rossini, Bellini, Donizetti, Verdi, Raphael, Michelangelo and others. Science is a continuous evolution, it is the continuous search for new mysteries that Creation jealously hides from us and that it lets us glimpse and gives us only little by little, through imperceptible glimmers. It would therefore be an insane pretension on our part to want to penetrate, ipso facto, the deep recesses of the unknown, to tear away with a slight effort the veil that separates us from this unknown and that the divine will has interposed between it and us, perhaps to make us feel its supremacy better, perhaps to make our incessant toil more arduous and meritorious. The objections which I have mentioned above are not, therefore, of such value as to combat and demolish a new source of profound and vast studies such as those which I shall here attempt to illustrate, basing myself on the texts of eminent men who have devoted time, sacrifice and ingenuity to this science, and on positive facts partly checked by me and partly reported to me by persons above all suspicion. Of course, neither my words, nor those of others will be able to prevent someone from saying: "I don't believe it". And why, excuse me, do you not believe it? On what arguments do you lean to deny without reason, without proofs, without arguments or demonstrations? You will answer me later on that the facts that I describe here are not reliable because they are extraordinary, because they are supernatural, because they are so many miracles. And here I wait for you. What, according to you, is an extraordinary event? Simply that which you ignore or which your mind does not conceive. What is a supernatural event? That which is new to you, but which is supernatural, that is, foreign to Nature, there is nothing, because even the strangest phenomena have their cause, their origin in Nature itself, even if they escape our intelligence. Certainly he who said, sixty or seventy years ago, that one day it would be possible to see through opaque bodies, that one day voices and sounds and even images would be transmitted across the oceans without wires, but only by means of ethereal waves, he who said this would be thought a fool. And yet Rontgen and his rays have come, and Hertz, and Calzecchi-Onesti, and Marconi with their apparatuses, and what was then considered a folly, as an extraordinary fact, as a supernatural fact, is now found very simple, very natural, without the multitudes caring to know the mystery that still

surrounds such discoveries and inventions. Finally, I will reply to those who may say that, if what I am going to say is true, Radiesthesia would perform miracles. Here is the great word, the Miracle, with which they think to shut my mouth. Now again I return to ask them: can you give me the precise definition of a miracle? The Catechism tells me: "A miracle is an extraordinary event accomplished by Divine Omnipotence, outside the laws of Nature. Therefore, according to this definition, in order for an event to be defined as miraculous there must be two essential, indispensable conditions: the first is that the event must be extraordinary; the second is that it must be performed outside the laws of Nature. But even an extraordinary fact is not in itself a miracle. For example: the aviator who flies, suspended in the air, performs an extraordinary fact, without for this reason performing a miracle, because he uses engines and propellers for the propulsion of his apparatus, which, by means of its wings, can navigate in space like a ship on the sea, because the resistance which the air opposes is in equilibrium with the other mechanical forces at his disposal. Therefore, if extraordinary results can be obtained by means of dowsing, we should not cry either to the supernatural or to miracles: we should simply observe the facts and try to discover the mysterious causes, which perhaps will remain so for years, for centuries, for eternity. And now, before going on to other things, I will say a few words about the relationship between Radiesthesia and Religion, in order to remove any scruple from the soul of my readers. Being a fervent believer myself, I wanted to know if the Church approved or condemned this new science, because I was told that abroad it had already raised some controversy not only orally, but also in newspapers and magazines. From what I have been able to ascertain, the conclusions are these: the Church does not condemn Radiesthesia at all when it is carried out for good and in favour of humanity; but she condemns it inexorably when it serves dishonest purposes, as, unfortunately, has sometimes already happened. But this can be said of any other science. Medicine itself is well regarded and blessed by the Church when it devotes itself to healing the sick and alleviating the ills that afflict mankind. Jesus himself, who was the supreme physician of souls and bodies, before speaking to the crowds who followed him from land to land, he healed the sick, and his disciples he admonished in these words: "When you go into a city, heal the sick whom you find there, and tell them: the Kingdom of God is at hand. (Luke, X, 8, 9). However, if the art of health care were directed towards evil (and this does

occur) it would not only be condemned by divine laws, but also by human ones. Besides we know that, especially in France, Radiesthesia is practiced with faith and passion by many priests and also by many Missionaries who use it to come to the aid of those savage tribes to whom they bring the salvation of the soul with the Cross and immense material benefits with their neo-science.

Chapter II

Historical notes

Despite the fact that the name has entered the technical terminology a few years ago, even Radiesthesia was practiced since the most remote antiquity by people who had evidently discovered and intuited this means to communicate with the unknown. The ancients must have had some knowledge that we still don't know today and that we can't explain. I cite one example among many that I could expound: how did the Egyptians illuminate the deep and dark funerary cells enclosed in their immense pyramids, given that no traces of torches, lamps, or lights of any kind have been found in the cells themselves? Yet it is certain that they must have been illuminated in some way, for we know that those sepulchral chambers contained, besides the mummified remains of those kings, all the luxurious furniture which adorned their last abode. I do not think we need speak of electric light; nor of gas or acetylene. Nor can we suppose that the illumination came from outside, because there were no windows. So who can give me an answer? Besides, coming to more recent epochs, the notion that many famous sorcerers of the Middle Ages were nothing but true and great scientists of their time, is now almost universally admitted. They, by that special intuition which guides and enlightens the minds of truly superior men, made discoveries and performed deeds which, to the popular and ignorant masses of their time, seemed to be such wonders as to attribute the merit or the cause to the spirits of hell. And as such they were condemned to the stake and to the worst tortures. But even today, in an age which we vainly call civilization and progress, even today we often deride the one who offers the world a new invention; and perhaps, if we could, we would condemn him to perpetual imprisonment as a histrionic, as a revolutionary, as a swindler. And this is why, especially in Italy, inventors have never had any luck, nor will they ever have any, because there is a great deal of mistrust in us, because we do not believe, we do not have faith in the genius of the Italians, in that genius which has always, in all centuries, been the shining star that has illuminated the world. But, to return to us, I want to narrate here a fact, that I take from the beautiful book of R. P. Bourdoux, former missionary at Mato-Grosso, entitled "Notions Pratiques de Radiesthésie" (Maison de la Radiesthésie, à, Paris) and that

proves how about 2200 or 2500 years B.C. the very ancient Celts had to practice, with great security and precision, Radiesthesia. In fact he reports that a friend of his, a very skilful dowser, Mr. Louis Merle of Capdenac, practicing in his studies, found that the famous dolmens and menhirs of Morbihan (France) are all located at the top of the angle formed by the intersection of the underground bands of water or minerals, but always outside (although very close to them) the so-called fields of influence. Merle carried out his studies and researches on more than 150 dolmens, menhirs and megaliths in the famous locality of Karnac in Morbihan and was able to ascertain that all these monuments, not one excluded, are located in the same position with respect to the underground water and mineral strata.

figura 1

We must therefore exclude the possibility that this is due to pure chance. If it had been a question of two, three, or four examples only, a simple combination might have been admitted; but in view of the precise disposition of all the aforesaid monuments, we must conclude that those who so placed them knew the way of detecting the course of the subterranean waters, and had reasons for avoiding the fields or zones of influence. At this point I think it appropriate to explain what is meant, in Dowsing, by a field of influence. Any watercourse or any underground mineral vein shows its presence on both sides of the watercourse, or of the vein itself, for a distance equal to the depth at which it is located (fig. 1).

figura 2

The zone A B which is $= 2 x$, represents the point or zone of influence. Later we will see how this is useful to establish the depth of the waters or minerals we want to find. In the case of the megalithic monuments studied by Merle, as I have said, they are found at the vertexes of the angles formed by the water courses (fig. 2) precisely at the margins of the zones of influence, without ever being included in them (a, b, c, d). But this is not enough. Several other interesting reliefs have been made by the same scholar on the same monuments: reliefs corresponding to the same conditions. Thus the menhirs (from men meaning stone, and hir meaning long) (fig. 3) are all found planted at the junction of at least three subterranean influences, but in the following ways:

1. When the third influence (or watercourse, or mineral vein) cuts the angle formed by the two others, at its end, the menhir is perfectly vertical.

2. When the third influence crosses the other two towards the inside of the corner the granite block is inclined, backwards, as if to move away from it.

3. When, on the other hand, the third influence crosses the others beyond the angle formed, the menhir is stretched forward as if it wanted to approach them.

figura 3

The menhirs are colossal granite stones, tall, and rather narrow in section in relation to their length, which are planted more or less perpendicularly in the ground, of which we do not know precisely the purpose and use. Perhaps they were funeral monuments of the prehistoric age; perhaps they were objects of worship. The facades or walls of these kinds of columns were rough, except for one side that was flattened and smoothed. Well: this side was always facing the vertex of the angle formed by the intersection of two underground currents. How? Why? Here is another of the many mysteries that perhaps nobody will ever be able to explain to us. Now all the above-mentioned coincidences are too demonstrative for us to see in

them a mere chance combination. But it is evident that if those very remote inhabitants of our globe adhered to certain laws, I would say almost, of construction, of their buildings, as we adhere to the building regulations, there had to be a reason that had its origins not in external things, not from the superficial conditions of the soil, but from elements that we can not conceive and yet were known and valued by them. On the other hand, it is well known that from the remotest antiquity the Chinese and the Japanese carefully studied the subsoil of the land where they wished to build their houses, in order to avoid those areas from which they could emanate harmful influences. Therefore, the Orientals also have this knowledge; therefore, they also know of the existence of harmful influences, or pernicious radiations. Nor is the choice of the location of the house sufficient for them; they are much more meticulous in the choice of their bedroom and especially of their bed. Now we will see later that modern dowsing attaches great importance to these factors of sanitary engineering. *Nihil novi sub sole*. But what or which means did they use for these subterranean researches made from the outside and that we today call prospecting? Obviously we do not know and perhaps we will never know precisely. But in some pharaonic sepulchres some small wooden spheres have been found suspended from a wire that crossed them axially. It could be that they were only pendulums already used in that Egypt so famous for the deep mysteries and for the vast science that reigned there and that still amaze us: sciences and mysteries that were the prerogative of Magi or Priests who brought in their tombs their prodigious secrets. Besides, there is a biblical fact that could be interpreted as a thesis in our favor. For we know that Moses, the Great Prophet, who led his people to the Promised Land, brought forth water from the driest desert to quench the thirst of the Jews who followed him. Well, what are we to infer? Was that water suddenly springing from the burning sands of the desert at the sole touch of the Prophet's stick a simple reality? Was it a miracle or is it only a symbolic image in the biblical narrative to let us know that he indicated with his staff the point where to dig to find the much desired water? But if we reread carefully what is written in Exodus, that is, what the Lord said to Moses: "Go before your people and take the Elders of Israel, holding also in your hand the rod with which you struck the river. And go. And I will stand before thee upon the rock in Horeb: thou shalt strike it, and water shall flow from it, and it shall quench thy people's thirst. And Moses did so in the

presence of the Elders of Israel. This fact seems to us to show how the search for waters in the deserts was done by the great Prophet with dowsing. It is not sufficient: neglecting here to speak of the mythological fables which teach us that Bacchus caused rivers of sparkling wine to gush forth with his wand; that Hercules felt the water flowing under his feet by means of the wand, and that with it Mercury, son of Jupiter and Maia, opened the gates of Avernus, we shall remember that the Scythians used it to guess the unknown; that the ancient Germans performed their spells with it, and that the Goths discovered the springs. The Etruscans, too, were great masters in dowsing and taught it to our Latin fathers, who used it to determine the position where to build their houses, imitating, in this, the ancient Orientals. Agrippa found, in the Agro Luculliano, the water to send to Rome, by means of a diviner maiden: for this reason this water was called virgin water. The Consul Paulus Aemilius, called the Macedonian (228 - 160 B.C.), used a dowser to discover the water with which to quench the thirst of his army at the foot of Mount Olympus, and the great Pompey himself resorted to the same system to find the liquid and vital element for his troops in that field which had been abandoned by Mithridates because of its aridity. Later on, under the reign of the Emperor Flavius Valens, about 370 AD, the Roman historian Ammianus Marcellinus (320 - 390 AD) described a method to obtain answers from the oracles by means of the pendulum. From all this we have to conclude that Dowsing was already practiced in ancient times and perhaps with greater success than what we obtain today. Leaving aside the fact that we do not know with precision up to what point this and other sciences were developed, in those remote times, there is a consideration that we must make, and it is this: that the more primitive people were, the more they had developed, in them, certain instincts, certain intuitions that our so-called civilisation and progress have made us lose. We can see this in animals. Today we call instincts certain manifestations of theirs that we do not even care to study or go into. When we have said the word instinct, we think we have said everything and explained everything. And, as usual, we are greatly deceived. What is instinct? It is probably only a more powerful perception of radiations that we are no longer able to grasp because our being, our organism, is dominated by other psychic and cerebral factors that alter its original faculties. But in animals, which have not undergone any evolution as a result of study, progress or discovery, their sensitivity to all the emanations

radiated by the bodies in the midst of which they live has remained primitive and acute. Proof of this is that they present earthquakes long before they occur. In the Middle Ages Dowsing was considered a diabolical practice and those who practiced it were called sorcerers and, as such, condemned to the most atrocious tortures and to capital punishment. But such punishments were provoked by themselves, because they, in order to impress their public more, resorted to complicated and choreographic rites, and surrounded themselves with scenic apparatuses which they used to make gloomy, attracting on them, imprudently, the attention of the Inquisitors. And when they wielded a simple hairpin like that of the Diviners, they pronounced invocations that did not fail to make their spectators' skin crawl: "By the power of the great Adonai, Eloim, Ariel and Jehowan, I command you to etc."

Of course, such prayers could not fail to attract the thunderbolts of the religious authorities who feared the spread of heresies and opponents of the Faith, especially since, in those times, the people could not believe that Nature could manifest its phenomena without visible agents; and therefore they attributed to Satan and his representatives on earth (i.e. sorcerers) every fact that could not be explained and that seemed extraordinary. In the fifteenth century, according to the monk Basil Valente, the Bulgarians and the Alemanni often used the wand with which they discovered important mineral deposits. In Italy, too, this small and simple device was used quite widely, especially by monks, among whom we will recall the Friar Barat of Vicenza and Eliseo of Ferrara. However, the theologians of the time disavowed them and condemned them, accusing them of practicing a demonic art; but their condemnation did not last long because many priests arose in defense of dowsing, such as, for example, the Jesuit Father Bernardo Cesi, an eminent mineralogist and tutor to the Princes of Este, the famous Father Kircher (the archaeologist who founded the eponymous museum in the Collegio Romano) and even bishops. In the 17th century the "hairpin" was no longer considered by political and religious authorities as an infernal instrument. On the contrary, it was respected and adopted, especially in France, even by the guardians of public order and the law; so that we know from the book by the Abbot of Vallemont published in 1693

and entitled *La Physique Occulte*, that the King's guards, led by a certain James Aymar, were able to find the tracks of three criminals from Lyon to Avignon, where one of the three was captured, while the others managed to take refuge outside the Kingdom. But already in 1602, a married couple of noblemen, Jean de Chastelet, Baron of Beausoleil, mineralogist, and his wife Martina de Bertereau, a very cultured woman, had discovered numerous deposits of metals, including gold, silver, lead, as well as various other minerals, by means of the wand. They used seven different rods according to the body they were searching for: this shows how they had pushed their studies to a remarkable perfection. But the interest and excitement that these discoveries aroused in all classes of society of the Kingdom, aroused lively controversy, particularly among scholars and innovators on the one hand, and the Clergy on the other; because the revolutionary spirit that was to generate the famous *Encyclopaedia* and culminate in the great tragedy of 1793 was already boiling in the pot. Nevertheless the Academy of Sciences of Paris received, in 1653, a pamphlet on the Divining Rod and made it the object of study and discussion. The conclusions later deduced by Chevreul (one of the academicians) were, however, erroneous because he ruled that: "the cause of the movements of the wand does not belong to the physical world, but to the moral one. I believe (he wrote) that, in the majority of cases in which the wand is held by an honest man who believes in it, the movement of the hairpin is the consequence of an act of thought of this man". And years and years went by until in 1900 Dowsing, began, slowly, to take hold. From then on this science has acquired ground and disciples; and a rather large literature has already been formed in France, in great part by priests, professors, doctors, engineers, etc., as can be seen from the Bibliography cited at the end of this modest writing. But the Radiesthetic Pendulum, which is perhaps destined to totally supplant the ancient wand or hairpin, did not officially reappear in our field until 1913, when Abbot Mermet, one of the most distinguished and popular French dowsers, presented it at the Radiesthetic Congress held in Paris in that year, expounding its theory and illustrating its uses and characteristics. From that day on, the pendulum has found numerous followers who seek to study its mysterious action and to use it in its infinite possibilities, especially in favour of Humanity.

Chapter III

Applications of dowsing

Notwithstanding what I have said so far, there will be many who, on reading the following pages, will laugh at it, and call me mad. But this does not frighten me, it does not destroy my convictions, nor does it disturb my sleep or alter my nervous system, because it would not be the first time in my life that, for being a pioneer and apostle of new ideas, new discoveries or inventions, I have been treated in this way, except to be told in a few years time, even if I still belong to the world of the living, that I was right. So it happened for the use of natural gases (methane) in the feeding of internal combustion engines. I was the first, not only in Italy but also abroad, to have this idea and to realize it in 1920. When I drove through Lombardy, Piedmont, Liguria, Emilia and even Tuscany with my car equipped with its cylinders full of compressed methane, everyone laughed at me, called me deluded, mad... and even worse. Today, at a distance of thirty years, the gaseous fuel I advocated has already entered into common use, although it is poorly used and by inexperienced people, and perhaps many of those who had shouted most strongly against me, have now become the most fervent supporters and propagandists. Forgive me, my dear readers, for making this little digression, which is entirely outside the scope of our subject. It was not out of mere vanity that I told you this episode of my life, but to show you that I am in the habit of studying technical and scientific problems thoroughly and severely: that I do not embrace an idea or a cause if I am not convinced of their goodness, and that I am accustomed to bear and fight the incredulity, irony and even insults of opponents in good or bad faith. Now to return to the bomb, as it is usually said, I will quote here all the main applications of Radiesthesia of which some are by now of indisputable reality, and others still subject to discussions because their results have not always been concordantly recognized. But we do not yet know whether the uncertainty of the latter is to be attributed to the dowsers who made the experiments, or to the objects experimented upon. Among the facts already admitted as real and positive we have:

Discovery of springs or underground watercourses with indication of their depth, flow, pressure, quality, etc.

Discovery of solid, liquid and gaseous mineral deposits namely: of iron, lead, mercury, silver, gold, copper, etc.; petroleum, methane, carbon dioxide, etc.

Archaeological research.

Search for hidden corpses and identification of those unknown, but of which you have a witness.

Search for hidden treasures.

Identification of the location of underground water, gas and electricity pipes and the points where there are faults, breaks, leaks, etc. in them.

Identification and military research: location of ammunition depots, regiments, batteries, etc.

Study of agrarian soil, fertilizers, crops, etc.

Quick analysis of any body.

Precise directions for location and orientation of homes, bedrooms, furniture, etc.

Identification of unfertilized and fertilized eggs into males or females.

Diagnosis on people and animals.

Indication of medicines to be used for various diseases.

Among the still unsure applications are noted:

Identification of the sex of the fetus before birth.

Diagnosis on a photograph of a sick person.

Remote searches for offenders, missing persons or objects with reconstruction of the route followed.

In the following of this writing we will indicate the operations to be carried out in order to achieve the above mentioned aims.

Chapter IV

Means and tools

I have just mentioned the pendulum and the rod or hairpin. These small, modest and very simple apparatuses are those that constitute almost all the armamentarium of the Radiesthesists. The best known and most used is the hairpin or wand, used especially by the Diviners, the other, the pendulum, of which today many already begin to use, is an instrument of recent introduction although it seems that the ancient Egyptians, and even the Orientals, used it with great success. It is not necessary, however, to believe that one or other of the aforesaid instruments is indispensable for all those who practice Dowsing, because there are individuals who, even without them, can pick up and perceive the radiations that bodies give off even from great depths of the earth. So I know a young lady who has the faculty of discovering springs or aquiferous, oil, methane, etc. layers, simply passing through any place on foot or by car, or even by railroad. For example, if she goes in search of oil, when she approaches an area where there is oil, even at great depths, she begins to feel sick, almost as if a weight were weighing on her head. As she approaches the strip or the source of oil, this weight descends along her body while the heartbeat increases in frequency, until, having reached the vertical of the strip or of the above-mentioned source, she is assailed by a very strong convulsive tremor and the pulse reaches 220, and more, per minute. Her state becomes distressing, to the point of producing fainting spells. And not only can she tell you the nature of the mineral that lies beneath her feet, but also the depth at which it lies and its quantity. She can also indicate whether there are hidden treasures, buried cities or monuments, and other such things. Its power of prospecting (let me use this word, which seems to me more appropriate) is no longer a mystery, nor is it any longer doubted by those who, with serenity of judgment, have controlled the constant work of many years of exercise, so that its power is now widely exploited by private individuals, companies and even some state administrations.

However, I would not like to confuse these manifestations, which are perhaps due to psychic phenomena, with mediumistic or spiritistic forms, which I am far from denying, but which, on the contrary, I loyally admit, indeed, with deep conviction. Spiritual manifestations are also of different kinds. I know, for instance, a young man of about thirty years of age who has the faculty of doubling himself. It should be noted, in passing, that the splitting of a person is a much more frequent phenomenon than is commonly supposed. This young man falls asleep, and, on our request, his spirit sets out, goes where we tell him to go—in a house, in an office, in a convent, etc., or even in the bowels of the earth; and while his body is immersed in sleep, his wandering spirit speaks to us through his physical person, and tells us what he sees or hears. In this way we can know precisely what we are interested in knowing. I recognize that such practices can be dangerous because with them there is no longer any possible secret; but they are very useful to us for the knowledge of the subsoil from which so much wealth and so many benefits we can get for our country and for Humanity. Certainly they can give us much better indications and much more precise information than those provided (with all the respect I profess for the official and gallant science) by the famous geological maps that many technicians throw triumphantly in our faces when we boast of the merits of the Rhabdomanti, Radiomanti, Radiestesisti, etc.. But between the geological maps and the latter I declare that I have much more confidence in the latter than in documents drawn up by men who, although they are very learned, reconstruct our globe, its history, and its evolution with the very few elements they possess, and which are nothing in the face of the mysteries of Creation. Those scientists who believe only in their doctrine and in their theories and who unquestionably condemn the possibilities offered to us by Rhabdomancy or Dowsing, make me feel like those eminent scholars, those reverend monks who condemned Christopher Columbus, Galileo Galilei and so many other beacons of Humanity, who had the most serious wrong to demolish their creed, the wrong canons of their knowledge and their theories. And since the word theory has fallen from my pen, I will pause for a moment to reply to those who always want to close the door on me with this word. But what is a theory? It is not a physical or natural law which, by its very essence, is immutable, precise, foreign and independent of human will and action. No. A theory is nothing else but the deduction of observations made by men up to a given day; until

a fact has intervened to show us that our knowledge, our observations, or even our experiences, in regard to it, were mistaken. This occurs frequently enough. For instance, when we say, "All work produces heat," we are expressing a physical law, because man will never be able to prevent this from happening. But when it was maintained that it was impossible to see through dense or opaque bodies, we were enunciating a theory which was fallacious, because by means of the Rontgen rays we know that there is no longer that famous impenetrability to light rays which was, for centuries and centuries, held to be a dogmatic truth. Even the atom was believed, until a few years ago, to be the last, the indivisible, the simplest particle constituting every body, every cosmic substance. Yet we know that the atom is composed of ions and electrons. It will be objected that chemical atomicity is one thing and electrical atomicity another. But are we quite sure that these ions and electrons do not represent some substance or thing which we do not yet know? Therefore, all things considered, I can only repeat what I have already said, that the truly wise, intelligent, and learned man must never deny a priori, nor admit anything without proof or without knowledge of the facts. But let us return to ourselves. There are persons who, being evidently endowed with a special organic or psychic constitution, are able, even without the aid of any instrument or mechanical means, to detect bodies or substances buried in the ground, even at great depths, and to determine their extent, their quality, etc.; and they are also able to determine, by means of their own observations, the nature of the objects they have discovered. But these are exceptions to the rule; for, in order to carry out such researches, we generally require some small apparatuses, which, from their extreme simplicity, often make strong spirits smile with compassion. And about this definition of "strong spirit" I confess that I have never understood it. For me, a strong spirit is one who is not afraid of ridicule, who does not misplace so-called human respect; but not one who makes himself a slave to the judgments or opinions of others. Thus many people consider themselves strong spirits because they do not go to church, because they are ashamed, perhaps, to make the sign of the cross or to take off their hat as they pass by when the door is already open, even though they received a religious education as children. Why do they do this? Because they are ashamed of it; because they do not want to be equated with the little women who everywhere and in every way prostrate themselves before the great Heavenly Father and invoke from him, with all

their faith and humility, the forgiveness of their sins, immense mercy, protection and help. Because, at bottom, they are timid and pusillanimous. And they believe themselves, by acting in this way, to be strong spirits! Poor things! They are but miserable and despicable creatures, always ready for apostasy or treason, because they lack principles and faith; and if they have any, they have not the courage to profess them. And this attitude of theirs is manifested in every field, for they will always be of the opinion of the strongest, they will always follow the predominant current whether in politics, in art, or in literature. After all, these so-called strong spirits are nothing but poor sheep capable only of bleating their yes before the most powerful. The instruments of the Radiesthesis are, therefore, two: at least for now. It may be that in the course of time another will be devised which will be more suitable for the purpose. The first and most widely used to date is, as I have already said, the rod or hairpin, which may be made of wood, metal or whalebone. The latter are preferable to all other materials because they represent a neutral body less susceptible than the others to the radiations of the bodies being sought. The simplest rod is the one that anyone can obtain by cutting a forked twig of a plant (fig. 4) in such a way as to have an inverted V. The preferred woods for the rods are hazel or elm. Olive and resinous woods must be excluded because the oil that the former contains and the resin of the others constitute an obstacle to their functioning. The twig must be quite thin and flexible and one year old. The upper end B C (fig. 4) will be 5 cm long, while the two branches AB and B D will be 25-30 cm long. However, I recommend, as the best of all, the one made with two whalebone sticks (fig. 5) about 25 cm long and united at one of their ends by means of a black vegetable thread binding. Instead of the thread, a ribbon or strip of fabric may be used. But keep in mind that each whalebone has a + and a - pole, which can be identified with the pendulum and therefore it will be necessary to join the two whalebones so that a + is joined to a -.

There are some who make their own metal rods, but in the opinion of some very competent people they are not to be used for the same reasons that make them reject oily or resinous woods. Not being able to find whale sticks, you can very well resort to the Indian cane of about 5 mm in diameter. I will not stop, therefore, to describe the different types of rods devised by various experimenters, each of whom believes to bring, with its own discovery, a small revolution among the drummers. The enumeration and description of so many different models which, after all, are all based on the same shape and on the same fundamental principles, would end up creating, in the reader, a confusion of ideas that would be detrimental to the correct interpretation of the criteria that I present here and that I have deduced even more from the instructions of distinguished Radiesthesiologists, than from my very modest knowledge. Therefore I suggest to stick to the whale hairpin as we have represented in fig. 5 according to the indications given by Monsieur Viscount Henry in the beautiful book entitled *Le Sourcier Moderne* (Librairie Agricole et Horticole, Rue Jacob, 26 Paris). He advises to join them, at their front end, with the flat sides matching each other because it is more comfortable to hold the small device (fig. 6). Wooden rods frequently break in the hands of the operator, while this does not happen with those made of whalebone.

figura 6

Steel rods can be used only for water research, while those of whale or guinea cane are of almost universal use. Before speaking of the pendulum, I want to mention another means of investigation that is almost between the hairpin and the pendulum and that is constituted by a real and simple stick of wood (hazel, willow or elm) 80 cm long which, while you hold it in your right hand at one end, will rotate around itself and will try to arrange itself orthogonally to the line of the same current. But, according to the opinion of the most skilled dowzers, the pendulum is preferable to the rod. It consists of a small sphere or cylinder of wood, glass or ebonite, suspended from a thread of linen, hemp or silk. The sphere or cylinder can also be made of solid rubber. The weight of the pendulum can vary from 30 to 70 grams depending on the dowsing power of the operator and on the length of the wire. Much has been discussed and is still being discussed among pendulum enthusiasts about the shape, weight, color, length of wire and material to be used for the wire. Some favour a weight of 25 grams, others 40, others 50; some say it should be spherical, others cylindrical; some claim that metal should be excluded, others use it; some use vegetable wire for the pendulum and others metal wire. In my opinion there is nothing absolute about this, because we have to consider that the use of these devices belongs to the field of mediumship, and as each medium has its own way of manifesting itself, so each operator must find the pendulum that best suits his temperament. In adapting the spherical form it is advisable to apply a point underneath. Obviously a completely metallic pendulum is not advisable, especially for the research of minerals, because it forms in itself a testimonial, but only for the metal corresponding to that with which the

pendulum is constructed. But an apparatus that I consider to be very appropriate is that formed by a small iron (not steel) pin enclosed in a copper tube and both contained in a case of copper.

figura 7

wood or plastic material (fig. 8 and 8 a) to which the thread or cord of hemp, linen or silk is attached. You can also use a small ball (fig. 8 b) crossed by a metal pin to which the thread is attached.

Other forms are those indicated in fig. 8 c), in ebonite and the one recently adopted by some in France, consisting of two hemispheres separated by a 5-pointed star diaphragm. This pendulum is also made entirely of ebonite with a central core of ivory (fig. 8 d). Finally, the late and great dowser Abbot Mermet used a pendulum hollow in the interior, because he placed the witness: gold, iron, copper, oil, etc. according to what he wanted to look for (fig. 8 e). As for the colour to be given to the pendulum (something on which not everyone agrees) it seems to me that black is the most suitable.

Finally, before indicating the way to use the aforementioned apparatuses, I want to speak of one of them that is, together, a wand and a pendulum and that brings together the symbol of Planet Pluto (fig. 9) because it includes: the hairpin, the pendular sphere and the cross. The cross also represents the 4 cardinal points. This small instrument, which is called the "Pluto wand", consists of two small round whale rods with a diameter of 5 mm and a length of 35 to 40 cm. Two of the ends of the rods are joined together by a black ligature 4 or 5 cm long, leaving the tips bare for about 2 cm so that they are inserted in a hole made in a small ebony ball or a 27 mm diameter cartridge case. At the base of the ligature, orthogonally to the axis of the first one, a magnetised metal rod is fixed, thus forming the arms of the cross. It will have a length of 10 cm. Its square section will have a side of 5 mm. Of course all these dimensions are merely indicative and not absolute. In addition, the indications N and S depend on the way the operator holds the stick, because if he looks up with the upper face, we will have, for example, North on the right; if he turns upside down, North will be on the left. How do we explain the movements of the stick and the pendulum? Many are the hypotheses advanced by the scholars who have dealt with these phenomena, and, among them, I mention, in Italy, Father Castelli of Bivigliano, Dr. Frontali and Dr. Pesce, and others; abroad, Henri Mager, Chevreul, Lemoine, Bulow, Bettkamps, etc., etc., but these hypotheses differ from one another. But as much as these hypotheses differ between them more in the terms than in the substance, we can conclude that the dowser and the dowser do nothing else than to collect the dowsing emanations produced by the different bodies, which emanations react on some special organisms that, by reflex, imprint to the small apparatuses the signalling movements. What these emanations are, and in what they actually consist, we do not know with precision. According to Noel it would be a matter of unknown forces, but which might be similar in nature to the Hertzian waves.

figura 9

Chapter V

How to use the devices

It is not enough to possess a wand or a pendulum in order to obtain the answers or the results one desires. It is not enough to have, say, a piano under one's fingers, in order to obtain from it harmonised sounds that are pleasing to the ear, and that can be called music. It is not enough to have a compass in order to know how to draw; a tacheometer to survey a terrain. Of any machine, tool or apparatus it is necessary to know the structure, the requirements and the operation to reach the prefixed purpose. But with dowsing instruments another completely personal requirement is needed, that is a special psycho-physical aptitude of which I will speak later on. Now I will say how to use the means I described in the previous chapter.

Wand or Hairpin. - The operator must grasp the ends of the hairpin with the palms of the hands facing up so that they can be held between the thumb and the other fingers when he clenches his fists (fig. 10). The arms will be a little far from the body and stretched forward so that the stick is in an almost horizontal position. It should not be held like this, however, except at the moment of using it, because if it is held too soon, the hands may become tired and cause cramps in the limbs. If the operator has dowsing qualities and is well trained, he will see the wand twitching in his hands with untameable force when he picks up the radiations he is seeking. The movements which the hairpin can perform are several. The most frequent and common one is that whereby the point rises up, assuming the vertical position. Sometimes this movement occurs with such violence that it strikes the face of the man if he is not careful. I know a talented veterinarian, an eminent dowser, who uses only his pendulum. Once he wanted to experiment with the hairpin, when suddenly, this, having entered a field of irradiation, straightened so violently in his hands that it struck him in the nose and chin, producing a beautiful blue of which for a long time he kept the most visible memory.

figura 10

Sometimes, instead of standing vertically, the stick lowers perpendicularly. Some other instead of describing an arc of 90° , it describes one of 180° , or, perhaps it rotates up to 270° and 360° . Finally it can rotate in your hands until it breaks. These different ways of behaving depend mainly on the sensitivity of the operator. However, the Pluto wand acts differently. In fact, if you hold it so that the north end of the transverse wand is facing the spring, the hairpin will rise, while it will fall when this end is downstream of the watercourse. Another strange fact that is found with this rod is that it does not give any indication when with it one ascends the current towards the source; but it moves when one follows its outlet. In this case it lowers, if the North of the sleeper is held on the side of the right bank and rises again when the North is held towards the left bank (fig. 11). Note that for the woman the movements are the reverse of the above movements which refer to the man.

figura 11

Pendulum. - The pendulum is held by its wire between the thumb and forefinger (fig. 12) of the right hand by right-handed persons and between the thumb and forefinger (fig. 12) of the left hand by left-handed persons; but since the length of the vertical wire must be adapted to each individual and to each type of research, it is necessary to find a way to lengthen or shorten the wire at the pleasure of the operator. The two most practical systems are those indicated in figures 13 and 14. The first consists of a wooden stick with a slit at one end into which the end of the wire holding the pendulum is inserted. By making the stick rotate on its axis, the wire is wound around it, becoming shorter or shorter. The other system (fig. 14) is even quicker and simpler in its operation because it consists of a wooden rod that carries a small wheel in which the pendulum wire slides. But I warn immediately that also the question of the length of the wire, to which some dowzers attribute a capital importance, is, in the opinion of authoritative pendulists, very relative and debatable because many believe that the preferable length is 25 or 30 cm. I do not exclude that there are individuals for whom the length may influence the research or the results they obtain; but I believe that these are exceptions. And I take this opportunity to repeat that in this field there is nothing absolute, because the factors that come into play are so many and so different in nature, that to want to establish a single rule is absurd.

A good rule, however, is to put a zinc ring in the index finger of the left hand during the operations. This ring will be made from a strip of sheet metal of the aforementioned metal. In any case, I will say here briefly how to proceed to find the precise length of the thread, according to Hector Mellin (*La Radiesthésie domestique et agricole*, Imprimerie Saint-Denis - Niort - France) from which I also take the relative illustration (fig. 15). Take, between the thumb and forefinger of each hand, the ends of the stick around which the wire is completely wound, until the sphere of the pendulum touches the stick itself. Then the ball is placed perfectly plumb on any object to be examined—a piece of rock, metal, coal, etc.—and the wire is allowed to unwind slowly, giving it an oscillating movement like that of a clock pendulum as the ball descends. At a certain point it will cease to oscillate and will assume a rotating movement, both to the right and to the left (see fig. 15: the movement is represented by the ellipse B, D, C, A, B).

When this variation in movement occurs, we will have reached the limit of the precise length of the wire, which will be measured from the point where the sphere touches the stick to the point where the wire is attached to the sphere. The length measured will be relative to the object on which the experiment was performed; therefore it should be noted in order to use it later for research on the material itself.

Chapter VI

Movements or manifestations of apparatus

I have explained how to hold the rod and the pendulum when one wants to operate with them. Now I will say how they are used in research and what movements they make that serve to interpret their mute responses. The hairpin, or wand, as I mentioned above, can act in the following ways:

1° partial or total torsion around its own longitudinal axis by overcoming the resistance of the stick;

2nd 90° vertical straightening (fig. 16);

3rd lowering perpendicular to 90° (fig. 17);

4th description of an arc of a circle or a complete circle (fig. 18).

The kind of movement, its amplitude and, let us say, its intensity and power, depend upon the greater or lesser sensitiveness of the operator. The hairpin is used especially by dowzers for water research; but some also use it for methane, petroleum, minerals, etc., although for the research of the latter the pendulum is preferable. Naturally I premise here one thing on which I will return to speak later: that for the use of the stick as for that of the pendulum are necessary: a good exercise or training and a sufficient dowsing sensibility. It is not necessary to believe that it is enough to have a wand or a pendulum to discover sources of water, gas, metal deposits, etc.. As in all the things, study and practice are necessary; otherwise negative results will be obtained and they will not be attributed neither to the pendulum, nor to the hairpin, but only to the inexperience or to the ineptitude of the operator.

Search for water with the wand. - For these searches the wand is perhaps preferable to the pendulum, because it allows the operator to walk more quickly on the ground, not moving except when under the influence of water. One may ask here what kind of irradiation water can emit. I answer that, besides the emanations coming from certain substances which the waters may contain (sulphur, iron, etc.), there are the irradiations produced by the rubbing of the subterranean waters against the walls, against the bottom and the vault of the channel through which they run. Stagnant waters do not emit these vibrations. In the search for water there are several questions to be answered:

1° location or location of the watercourse;

2° its depth;

3rd its range;

4th his direction;

5th water quality: drinking water, mineral water, thermal water, etc.

We must premise, however, that underground water courses offer some particular characteristics, some phenomena that we do not find in other cases. These characteristics are called lines of force or harmonic lines of the main current (fig. 19) and are represented by many lines parallel to the strand of the current which impress on the rod jumps well known to dowsers.

figura 19

There are 8 on each side of the watercourse and each of them will make the hairpin straighten, as in fig. 16, or will make it describe an entire circumference, as in fig. 18. The researcher, starting from point A, will move along line A E, which will be orthogonal to the course of the river that he will have previously localized by prospecting on the spot. Along the

aforementioned line A E he will count the seven movements made by his rod. The eighth will indicate to him the bank, or limit, of the channel. Throughout the crossing of the channel the wand will continue to twitch, and thus it will be easy for the dowser to determine the width C D. Walking through any countryside in search of water, he will feel at a certain moment (if there is water) that his wand will straighten at a certain point. Having fixed this point on the ground, either with a wooden stake or with a stone, the researcher will continue to walk through the terrain, always with his rod in his hand, describing a circle whose centre is the point fixed with the stake or with the stone. By necessity he will come across another point where he will have another manifestation of his hairpin. This second point (which will also be fixed on the ground) connected with the first one found, will give him a brief indication of the course of the watercourse. Following the path between the first and the second point, he will detect the underground course of the water current by the movements of the rod, which will turn in his hands if he goes towards the source, while it will remain still if he follows the downward course of the canal. Working in this way, two results will have been obtained: the indication of the width of the watercourse and its origin. Now it is necessary to determine the depth. There are several methods adopted by dowsers, but the most practical, because it is the simplest, consists in measuring the distance between the center of the stream and the point at which the rod will straighten. This distance will correspond to the depth of the water because (fig. 1) point A or point B represent the limits of the zones of influence. This method is called the 45° method. Another system for determining depth is one I have seen practiced by a dowser of some skill. He grasps the rod by the two branches, holding one in each hand, sufficiently distant from each other. Then, bending over a little, he makes a vigorous to-and-fro movement with his arms, and counts these movements until the fork is straightened. Each movement corresponds to a length which he has first determined: 1, 3, 5, 10 meters, etc. This method has always given precise results. This method has always given precise results not only for water but also for oil, methane and other bodies. Let us now come to the capacity of the underground canal, that is to say, the quantity of water which it can supply in a minute, in an hour, etc., and which can be used to determine its capacity. This specification is quite difficult and uncertain, especially with the rod. At most one can know with it whether the amount of water will be a lot or a little, depending on the

violence and amplitude of the movements of the hairpin. If the hairpin straightens up vigorously or turns completely, this will indicate a lot of water. As for the amount of water, I recognize that the pendulum can give us more reliable clues than the stick, because with it you can also proceed mentally with excellent results. With the wand, however, it is necessary that the researcher isolates himself, abstracts himself completely for his research and that with his will he wants to find only drinkable water. Working in this way he will be able to pass over mineral or thermal springs without his apparatus manifesting any movement. But, I repeat, it is necessary that he absolutely eliminate with his mind any other search. But before continuing on the search of the waters, which constitutes one of the most frequent applications of dowsing and especially of Rhabdomancy, I consider useful to give some brief notions of hydrology to the reader who would like to dedicate himself to the above mentioned search. Perhaps it may seem, to some, out of place, but since this book is a practical manual, I think it is good to offer to those who follow me any indication that may facilitate the task and, if profane in the subject, teach him some elementary principles of geology that will serve as a guide in his research. What is the origin of the underground waters? What is their distribution? At the time of its formation, the Earth was nothing more than a great incandescent mass which, over thousands of years, gradually cooled and later became covered with water from which the oceans, lakes, rivers, etc. were formed. Therefore the return of the waters to their beds, in the abysses that had been created, caused the salient parts of our Globe (not submerged by the waters themselves) to undergo, with the passing of time, all the consequences of the mechanical action of the winds, frosts, thaws, rains, etc., etc., which disintegrated them, giving rise to the formation of clays, sands, limestone and other sediments which, slowly depositing themselves in the places where the waters were calmer, constituted sedimentary terrains. But these did not always remain such because, at different times, the earth's crust underwent numerous and complicated perturbations that gave rise to very different geological trends. Of such perturbations those which perhaps have had the greatest importance, not so much for themselves as for their consequences, are the uplifts and sinkings, let us say. Of course, each of these colossal movements of the earth's crust affected a more or less great thickness, which included various layers of soil that, remaining adherent to each other, took the disposition, the form of the lower band that will serve

almost as a support. Then came the rain waters and those coming from the melting of the snows that dug, here and there, enormous furrows, more or less wide and deep that we call erosion valleys (fig. 20).

figura 20

The uplifted strata form an anticline, while the downlifted strata form a syncline. Note the difference between the erosion valley and the syncline valley (fig. 20). In the first we see the interrupted layers as in the fractures, while in the other they follow the superficial course of the soil. But the waters, whether they remained on the surface of the Globe or were rainwater, infiltrated through impermeable layers or through cracks, in depth, contained and held by impermeable areas of the ground thus forming immense water reserves that man often tries to discover and exploit. The structure of the various layers that constitute the earth's crust (I was going to say the epidermis of the globe) is very varied because there are loose layers, such as sandy ones, and there are rocky ones. Naturally, the location of the aquifers depends a lot on these structures.

Highly permeable strata. - They are represented by very fissured soils that allow the easy circulation of groundwater not only from top to bottom, but also vice versa. Sometimes these fissured soils extend for hundreds of kilometres. We have a very singular example in France where it is known that the waters of the Aisne River take only 60 days to discharge into the Paris aquifer, which is a good 200 km away.

Slightly permeable strata. - They consist of soils composed of schists, quartz or poorly fissured limestones.

Impregnated layers, formed by sand and certain clays which have the property of retaining water and a strong imbibition power.

impermeable layers, which may consist of either a layer of compact limestone or a layer of clay. Sometimes these layers can have cracks that allow the waters to filter through, allowing them to descend and expand into a lower deposit. This explains the existence of aquifers above and below the impermeable layer.

Underground lakes. - They can be considered as natural underground cisterns into which a water course is discharged. The overflowing water gives rise to numerous rivulets that spread like the roots of a plant. But sometimes, in summer, when the watercourse that feeds the underground basin dries up, this too naturally runs out and with it also the little rivers that arise.

Lakes and artesian currents. - The natural cisterns of which I spoke earlier, or to be more precise, those cavities within which water is collected, generally assume the form of a basin or a basin within which the water will precipitate with the pressure due to the difference in level existing between the basin A and the source B of the water (fig. 21); and with this pressure, diminished by the losses of load, etc., the water will flow out, from a hole that was made in A, up to the height of C. The aquifer layer constitutes that of the level or ground waters.

figura 21

Springs. - They are formed, for the most part, at the points where an underground watercourse flows to the surface of the ground; naturally there are, therefore, those which come from great depths; others, instead, which spring because the impermeable layer which conveys the water emerges on the ground. Not all of them are perennial. Some of them are intermittent; they dry up in summer and do not resume until the rainy season.

The reserves of water in the interior of our globe, I repeat, are immense, incalculable. From the external conformation of our Planet, from its superficial structure, we can also deduce or have some summary indications of the points where to carry out the perforations to make the beneficial and vital element come out. But such indications are very vague, generic and often fallacious. The most knowledgeable geologist will be able to say that in a given area, in a given territory, within a radius of 500, 1000 or more metres there is a probability of finding water; but he will never be able to indicate the precise point where to drill, he will never be able to tell us at what depth the water will be found, nor its quantity, nor its flow rate. And here is where Radiesthesia comes in, for which, whatever some may say, there are no secrets. Research with the wand, as with the pendulum, should never be carried out when there is a thunderstorm, when the wind blows or when it rains or even when the operator is not in good physical and psychological conditions, because he could incur in serious errors. How do we explain the phenomenon of the wand? On this point everyone agrees that the rod, having the shape of a point, when it is placed in a fluidic,

electric, magnetic or telluric field, has the property of discharging this field. Let us suppose, by way of example, that an operator in research work holds the tip of his rod on the vertical plane A B C (fig. 22) that rises from the bank of an underground watercourse.

figura 22

This plane A C is made up of the vibrations caused by the rubbing of the electrified molecules of water against the ground. Therefore, when the researcher introduces his rod into B within the aforesaid plane, this will discharge through the rod itself and the operator's body, according to the break A B D E, the current into the ground. But instantaneously the field A C is reconstituted and meets again the stick which, if at the beginning of the operation it was neutral, has become positive due to the passage of the current B D E; and since in this case we are faced with alternating vibratory currents, the second fluid A C will be negative. The meeting of positive and negative at the tip of the rod causes an unbalance that makes it rise or fall.

Research of water with the pendulum. - In principle, searches made with the pendulum differ little from those made with the rod: the greatest difference lies in the movements made by the two devices. But also the precision of depth, water quality, etc. is better achieved with the pendulum than with the hairpin. For water research one operates more or less as with the wand. The dowser, holding, as we said, the pendulum wire between the index finger and the thumb (fig. 12), walks slowly, trying not to move the arm that holds the instrument, in the area of land to be studied. He will have to pause from time to time so that the pendulum is not affected by the movement that walking may impart to it. If there is water in the area in question, at a certain point the pendulum will begin to rotate and its rotation will be all the greater the closer it is to the vertical rising from the underground spring or stream. He will then operate as we have said he would do with the rod. He will establish the point corresponding to the maximum rotation by means of a peg or any other mark left on the ground, and he will go along it in every direction until he finds other points on which the pendulum will reproduce the ample circles already described.

Search for depth. - The operator places himself above one of the points marked on the ground, which correspond, as we know, to the vertical line passing through the underground water center. He waits for the pendulum to rotate. As soon as this occurs he begins to count in a perfectly regular and rhythmic way: 1, 2, 3, 4, etc., establishing first whether each number corresponds to 1 m, 5 m, 10 m, etc. When the instrument stops, the last number counted will be the one that indicates the depth of the water. So if I had established, a priori, that each number corresponds to 5 m, and if the pendulum lets me count up to 15 I would have: $15 \times 5 = 75$. To make the counter-check of the above calculation we can operate as follows: we keep the pendulum motionless and we count, as in the previous case. The pendulum will have to start moving when the number already found is pronounced. Instead of simply counting, one can also strike the ground in a cadenced manner, either with the foot or with a stick. Each blow will be answered by a certain length. But, let us be clear, the calculation of depths made by the methods outlined here is only approximate. One must always

allow for a margin of 20% more or less. More precise is the 45° system we have just mentioned.

Source range. - The operation is the same as for the search for depth. First the unit of measurement is established: the litre, the decalitre, the hectolitre, and the count is made: 1, 2, 3, 4, 5... etc., from the moment in which the pendulum is given air until the moment in which it stops. The last number counted gives us the quantity of litres, or decalitres or hectolitres that the spring itself will dispense in one minute.

Water quality. - For this research it is necessary to resort to another method, even more cerebral than the previous ones. It is necessary that the researcher fixes well in mind the quality of the water that he wants to find; everything is here. So if he wants to find fresh drinking water, he will have to think only of it and will end up finding only this. This may seem absurd, but it is just so. A more precise and better method is to have a witness, that is, a sample of the water one is looking for. So if the dowser wants to find drinkable water, he will hold in the hand that holds the pendulum (or in one of those that hold the wand) a bottle of drinkable water. If he searches for sulfur water, he will hold in his hand a vial containing a little of this water.

I have spoken of gyrations of the pendulum, but sometimes and in certain individuals the action of the pendulum is manifested by oscillations instead of rotations. The results are, however, always the same. The movements of the pendulum (and I think I have already mentioned this) are four: two of oscillation and two of rotation. The oscillatory movements can be longitudinal or transversal. For the first ones we mean those that are carried out in the vertical plane passing for the middle of our body: therefore with a motion of to and fro that approaches and moves away the pendulum from our chest. The second ones, instead, parallel to our face and, that is, from right to left, or vice versa. The rotary movements can turn from left to right, according to the course of the spheres of the clock or turn in the opposite

direction. For many eminent dowsers, the rotation to the right is favorable and is indicated with letter B, which means good; the rotation to the left is, instead, a bad sign and is indicated with M, which means bad. The most frequent and general movements are, however, two: the longitudinal oscillatory which corresponds to the negative; and the rotatory to the right which corresponds to the positive. It is necessary to consider these data well because they are fundamental in practice.

The first application of this principle is in the determination of sex. In fact, if on the back of the right hand of a woman we let our device hang at a distance of about 1 cm, we will see that almost immediately it will start to move turning to the right. If we do the same experiment on the right hand of a man, the pendulum will oscillate but it will not turn. This is a fact that everyone can check and that alone should, at least, arouse some curiosity in the incredulous. We shall see later that on the same hand we shall have other manifestations of the pendulum which no one can deny even if we do not yet know the cause or the reason. But to have the polarity of the humans we will keep in mind that in the man the pendulum will oscillate on the back of the right hand and on the palm of the left one, while it will turn on the back of the left hand and on the palm of the right one. In the woman we will have the inverse: turning on the back of the right hand and on the palm of the left one.

Chapter VII

Dowsing faculty of individuals

The most skilful and learned dowser, R. P. Bourdoux, of whom I have already spoken and from whom I take part of this writing, expressed himself on the subject of this chapter.

"The aptitude for Radiesthesia is a gift like that of being a poet, musician, mathematician, etc., a gift that contains different degrees and the possibility of perfecting oneself. But who, then, absolutely cannot become a poet, musician or mathematician? Unless we are abnormal, each one of us can, by study and will, come to make, with greater or lesser success, verse, music and mathematics. We all have some aptitude for doing some of this. Great poets, musicians, or mathematicians are rare: but this does not prevent the possibility of small ones. I say the same thing about Radiesthetes. Everyone can become one more or less, with greater or lesser ease. Good dowsers will be rare, but beside them there will be less good and mediocre ones. Indeed there will be those who will be of little value in a given kind of research while they will be able to emerge in another, because Radiesthesia admits specialties among its partisans".

From the above words two conclusions are evident: 1° that every individual can become a dowser even if he is not born such; 2° that it is necessary, however, a cultivated and continued training or exercise with fervor.

One should not despair or be discouraged if the first results are not fully satisfactory because this happens in every branch of study. Many are born dowsers without even suspecting it. Others would pretend to use the pendulum from their first experiment, as they see it used by those who have been using it constantly for years. On the other hand an excessive dowsing

sensitivity or faculty is not a great benefit because the pendulum, in the hands of those who are equipped with it, will make so many uncontrollable and disordered movements as to prevent the correct interpretation.

Therefore, a dowser of average psychic potentiality is preferable, because he will be able, with practice, to develop it to the maximum degree with the maximum perfection of reception.

HOW TO EVALUATE THE DOWSING SENSITIVITY OF A PERSON

There are several means by which we can know our dowsing power, either by using the wand or by using the pendulum. There are two methods of knowing by the wand.

The first one consists in accompanying, in the country, a dowser and to walk at his side holding, like him, the hairpin in hand. If, arrived at a certain point, the dowser's fork turns on itself, while yours does not move, you have immediately a negative proof: you have, that is, little dowsing aptitude.

The second method is just as simple. Go to a place where you know that there are wells or springs, and, with your wand in your hand, walk through it far and wide. If it does not undergo any contortion, if it does not make any movement, it means that you have little or no sensitiveness of this kind. But do not be discouraged by this. Try and try again and again, because perhaps in time the dowsing sense will develop in you. With the pendulum the experiments are even easier because everyone can do them comfortably at home.

1° Experiment. - Take a pendulum and keep it suspended on your other free arm, stretched horizontally (fig. 23), or on that of another person. You will see that after a few moments it will begin to move and oscillate in the longitudinal direction of the extended arm. However small these oscillations may be, they will be a favorable clue.

figura 23

With time and practice you will become a good pendulum player. Even if the instrument remains immobile during these first trials, do not be discouraged.

2° Experiment. - Ask a friend or any other person to cross their arms and place them on a table (fig. 24) and suspend your pendulum over them. Perhaps it will not start moving immediately, but after a few moments you will see it move slowly, then describe ellipses and finally take a decisive rotatory movement. This, too, will be a good sign.

figura 24

Keep your feet flat on the floor and do not cross your legs during the exercises.

3rd Experiment. - The dowsing sensibility of a person can be measured on the center of the nervous system, at the solar plexus situated behind the stomach and in which all the nerves of the Great Sympathetic converge. But in order to proceed to these measurements it is necessary to hold the pendulum with one hand so that it is about 30 cm from the chest and at the height of the stomach, while pointing the other hand in the hollow of the stomach. The arm that holds the pendulum must be free, bent without effort or rigidity and the person who practices the experiment on himself must be facing east. Soon the pendulum will begin its rotary motion and the number of turns it makes will indicate with absolute certainty the degree of sensitivity of the experimenter. And so we will have:

No sensitivity: no more than 15 turns;

Weak sensitivity: 15 to 30 turns;

Medium sensitivity: 30 to 50 rpm;

Good sensitivity: 50 to 100 rpm;

Hypersensitivity: over 100 rounds.

But it is not enough to count the number of revolutions the pendulum makes; we must also take into account the speed and vigor with which it turns. If the movement is slow, the sensitivity is weak; if it is rapid and decisive, it is ultra-sensitive.

4th Experiment. - Even by simple contact with a recognized Dowser we can deduce the dowsing sensitivity of another person. So, suppose that the first one makes the pendulum spin on his free arm and that another one touches it lightly in any point of the body. We can find 4 different cases:

1° - At that contact the pendulum stops instantaneously. This proves that the person who has touched the operator has a polarity different from his own: or that he has no dowsing aptitude or sensitivity.

2° - At that contact the pendulum slows down its movements. This shows that the intervening person has less sensitivity than the operator.

3° - The movements of the pendulum are not altered in any way. In this case the sensitivity of one and the other are equal.

4. The movements of the pendulum increase in amplitude; and then we know that the person intervening has an aptitude superior to that of the pendulumist himself.

Here it is useful to warn that for every operation performed with the pendulum (and also with the wand) different factors are required, some of which depend on the person of the dowser himself and others on external and independent elements. Among the first ones, that is among those inherent to the operator, we place: the health and the state of mind; among the second ones we have: the wind, the rain, the thunderstorms, etc. etc.. The position of the person also has its influence. In fact, stand straight facing East and keep the pendulum suspended at chest height. It will turn to the right. Without making other movement, raise the left leg so that that foot doesn't touch the ground anymore. You will see that immediately the pendulum will stop its rotations. Apart from the fact that in order to operate with the pendulum or with the stick, it is necessary that whoever wants to make an experiment or a research be in good conditions of health and spirit, not only to be able to capture the irradiations, but also so that they do not aggravate those physical or spiritual imbalances that constitute in themselves a form of illness. Therefore it is necessary that the pendulist be, I repeat, in good health, and that his mind be tranquil, his spirit serene. As for the meteorological elements, these can have great influence on the results of operations. The wind may impart to the pendulum movements which prevent its true manifestations and readings. It can also prevent the discharge of polarized surface areas. Rain is another enemy of Dowsing because it splits the atmospheric layers and strongly disturbs the radiations. Thunderstorms, etc., constitute, as is well understood, very powerful obstacles to pendulum operations. But, in addition to the above mentioned contrary factors, we still have to count:

fading, as in the case of radio equipment, because there are hours, days, and even months in which the capture of body radiation cannot be carried out. This phenomenon occurs especially during thunderstorms, sultry or excessively sunny days, etc.

autosuggestion can sometimes influence the dowsing apparatus. It is therefore necessary for the operator to establish, first of all, what he wants, so to speak, to know from his little apparatus and to abstract himself completely. He must become a simple machine, absolutely without will or thought. Very often some dowsers think to avoid autosuggestion, stiffening their arm so that it looks like a metal rod or a piece of wood. This is a very serious mistake, because the stiffening of the arm prevents it from moving freely under the influence of the radiations which give the arm a push that makes the unbelievers believe that we ourselves make it turn, while it is it that drags our hand. Therefore let the arm be free and light.

And since I am speaking of obstacles in the use of the pendulum, I will immediately mention another negative phenomenon that unfortunately often occurs and from which we must beware if we do not want to incur in serious errors. This phenomenon is due to what is called remanence, i.e. the persistence of radiation emitted by any body in a place from which it was then removed. It is because of this phenomenon of remanence that the carrier pigeon finds his pigeonhole; it is because of this same phenomenon that the dog follows the tracks of his master or of the game. Thus, if we examine with the pendulum a table, a chest of drawers, or another piece of furniture, or even a piece of ground on which, for some time, there has been placed some object of gold, our apparatus will feel the radiations even after a long time that the said object has been removed. The permanence or remnance of these radiations will have a duration proportional to the duration of the permanence on the spot of the body which was placed there. The same occurs with photographs. Depose a photograph successively in different places, and then burn it as well. You will find with your pendulum

both in the places where the photograph was placed and on the ashes the remaining vital radiations of the person who was reproduced in the photograph. This phenomenon is of the utmost importance and must always be kept in mind by the operator if he does not want to be misled. However, there is a way to know if we are dealing with the real presence of a body or with its remnant. The eminent French dowser Lacroix-à-l'Henri suggests this method: a thick sheet of white paper is placed between the radiation and the pendulum. If the pendulum remains stationary, it means that there is only the remainder, but not the object that is sought, because if this were still in place, the pendulum would complete its rotations. On the contrary, the most illustrious dowser, recently taken to science and to the world, Abbot Mermet, used another system: he suspended his pendulum at the height of the forehead and then he made it slowly descend along his body. If the pendulum reached the ground without turning, it was a sign that the object was no longer there, but only its remains. If the pendulum, having arrived at half height, began to move, we could deduce that in the ground or in the places we had envisaged there really existed the body that forms the object of our investigations.

Right-handed and left-handed. - We know that there are people who, in their usual work, make better use of their left hand than of their right. These are rather rare and constitute anomalies. Those who have this peculiarity are called left-handed, while the others are called right-handed. Even in the dowsing field there are right-handed and left-handed people depending on whether they hold the pendulum with one hand or the other. This depends on the fact that while the right-handed one lets a positive fluid emit from the fingertips of the right hand, the left-handed one emits it from the extremities of the left hand. It is a question, now, for my reader, of knowing whether he is the one or the other. This is not difficult to clarify. Take a horseshoe magnet, and regulate the length of his pendulum on the positive pole of the magnet, holding the device with his right hand. Then, when he sees it turn in the direction of the arrows on a clock, he immediately presents it to the fingertips of his left hand. If the pendulum continues to turn in the same direction, the operator will be left-handed. If, on the contrary, the pendulum will change its rotation, that is, if it will turn in the opposite direction of the

balls of the clock, the operator will be right-handed. A reproduction of this last experiment can be obtained by holding the pendulum with the left hand and exposing it to the extremity of the fingers of the right hand and to the positive pole of the magnet. If the pendulum turns in the direction of the balls of the clock, the pendulumist is right-handed.

Human hands. - One of the initial and fundamental experiments that every dowser must do is the one on human hands, because it shows us that the pendulum works strictly in relation with the sex of the persons. I have already said this on page 66. But there is more. We know that on the back of a man's hand the pendulum oscillates while on the back of a woman's hand it turns. Well, if we suspend the pendulum on the palm of the female hand the pendulum will oscillate. In other words, we will have inverted movements. Where, rather, we will find that the movements are similar, it will be at the tips of the fingers, because the pendulum, both for men and women, will oscillate orthogonally to the fingers. Here, too, we may find exceptions. But where are there no exceptions? Let us recapitulate what I have said up to now; to succeed in the dowsing operations it is absolutely necessary to follow the following rules which are too often neglected:

1 - Place your feet firmly on the ground so that you have maximum contact between the soles of your feet and the ground;

2° - Do not wear shoes with soles made of rubber, cork or other insulating material during the tests;

3° - Don't keep your legs crossed;

4° - Possibly keep the elbow of the arm holding the pendulum resting on a table so that the hand remains firm, without rigidity, while the other hand is either lying on the table or is touching a witness, photograph or other object;

5° - Preferably face east;

6. Avoid operating on bodies that have remnants of other bodies or persons. For example: using the dial of Dr. Marty, it will be opportune for each reading to place a clean sheet of paper between the dial and the witness. If you do not have a sheet of paper, you can also dust the dial with a clean handkerchief, or blow on it repeatedly;

7th - it is also indispensable to be in good physical and psychic condition. The spirit must be absolutely serene and not subject to internal or external influences or suggestions. Therefore, I strongly recommend that you operate alone, or in the presence of a very few people who are well disposed and confident in the results of the experiments they are witnessing. Let's remember that a skeptical or malicious individual, can very well, with his mental irradiations, completely disturb the work of the most skilled dowser or diviner. That's why I suggest to all colleagues to never, and for no reason, to operate in public and even less to take part to competitions or contests. Dowsing operations are not football games or gymnastic exercises; they are very delicate things that can be easily disturbed. And as the operating acts must be performed with all possible caution, and with the assistance of very few people, so also those of the dowser must be surrounded by infinite precautions if good results are to be obtained. I insist on these rules not for pedantry, but because they constitute the essential basis of our operations.

Chapter VIII

Some elementary notions of physical dowsing

It seems to me indispensable, before continuing in this work, to mention briefly some elements of physics which, in order to be strictly connected with Dowsing, I have thought to call with the generic name of Physical Dowsing. I say that it seemed to me indispensable to speak about them because we will often quote them or resort to them.

Cosmic forces. - They are those that come to us from above and radiate in a vertical descending direction. Mrs. Jacqueline Chantereine defines them as follows: "Cosmic forces are composed of multiple life waves of heat, light, electricity, weather, irradiation and sidereal energy."

Telluric forces. - These consist of innumerable emanations from the subsoil. The telluric currents always walk horizontally.

Magnetic field. - This is the portion of space within which the compass needle undergoes a directing action. Three elements can be distinguished: its function, its direction, and its intensity.

Magnetic flux. - It is the set of forces that pass through a magnetic field.

Lines of force, to which we have already alluded on page 57, constitute a bundle of curves which fill the whole magnetic field and which, at every point, indicate its direction. Every body has a certain number of such lines. Thus water has 7 and gold has 11.

Permeability. - This is the ratio of the magnetic induction that a body absorbs when it is placed in a magnetic field. Example: Soft iron has a very high permeability.

Calamitation by influence. - When we place any body in a magnetic field, this body takes an induced magnetization which, generally, ceases when we remove the same body from the inductor magnetic field. These last two laws (permeability and calamitation by influence) are very important in dowsing, because they will be often recalled when I will speak about remanence and impregnation.

Natural magnets. - These are those which have the well-known power of natural attraction. The action which they exert upon iron is called magnetism. This action may be exerted at a distance, either in a vacuum or through magnetic substances. Magnetism is diminished by high temperatures. Fire destroys the magnetism of magnets, but not human magnetism. This explains why we find by means of the pendulum the vital radiations emitted by the remains of an incinerated person, as well as in the ashes of a letter written by the cremated person.

Artificial magnets. - These are those magnetized by influence. The bodies so magnetized, and which are said to be paramagnetic, may be: iron, nickel, cobalt and all their compounds. The soft iron does not preserve the magnetization obtained by contact. It constitutes a temporary magnet, while steel, which preserves that which is communicated to it, forms a permanent magnet.

Declination. - Angle formed by the geographic and magnetic meridians.

Inclination. - Angle formed by the magnetized needle with the horizontal of the magnetic meridian. The north pole is above the horizontal plane.

Compass. - As everyone knows the compass is composed of a graduated dial and a needle with two points, one of which is magnetized and always points to the North. The compass was also invented by the Chinese about 1600 years BC. The two points of the needle have different colours: one is white and the other blue. The latter is the magnetic one and indicates North, while the other marks South. Why this fact? We know that the Earth is divided into two hemispheres whose base is the plane passing through the Equator. The Northern or Boreal Hemisphere has the negative sign (-); the other, the Southern or Southern Hemisphere, has the positive sign (+). But since we know, by Coulomb's law, that two forces of the same sign or name repel each other, while they attract each other when they have opposite sign or name, it follows that the magnetized point of the compass needle, whose point has positive sign, is attracted by the North Pole, negative. Now if we examine the way the pendulum behaves relatively to the compass needle we will see that:

it turns in the direction of the clock spheres (positive sense) on the tip that turns to the North;

it turns in the opposite direction (negative direction) on the tip looking to the South;

it stands still at the midpoint, or neutral point, of the needle itself.

On paramagnetic bodies the pendulum always turns in the positive direction. The vertical parts of any metallic mass all have their positive pole (South) at the top and their negative pole (North) at the bottom. In fact if we put a compass near the foot of a vertical metallic rod or of a radiator of a radiator or of any vertical iron rod, we will see that the white point of the needle will be attracted by it. Vice versa, if we present it to the upper part of the aforesaid metallic objects, we will find that it is the blue point that will be attracted. Similarly, if we replace the compass with a pendulum, we will see that at the top it will turn positively and at the bottom negatively. From which we may conclude:

1° - that the lower part of the metal bodies is positive;

2° - that their top is negative;

3° - that the North Pole of the compass needle is positive;

4° - that the magnetic North Pole is negative;

5th - that the South Pole of the needle is negative;

6° - that the magnetic South Pole is positive.

All this will help us to identify the poles of a magnet, since the negative pole of the magnet will attract the positive pole of the needle and make the

pendulum turn to the right (positive mode): the positive pole of the magnet will make the pendulum itself turn to the left (negative mode), while it will attract the negative pole of the compass needle.

Polar Bodies and Equatorial Bodies. - Depending on the direction taken by their irradiations, bodies are called polar or equatorial. The former are those that radiate on the North-South line; the latter are those that radiate toward intermediate points: NE-SW; NO-SE, etc.; these bodies are called semi-polar or semi-equatorial.

Chapter IX

Fundamental ray solar ray, capital ray

It is called Fundamental Ray (RF) the direction that the radiations, more or less horizontal, emitted by a body take toward a cardinal point or toward an intermediate point. The importance of the knowledge of this RF is enormous because with it we can distinguish, identify a hidden body, being already compiled, by work of dowzers and distinguished scientists, a table from which the fundamental rays of the minerals are detected, which rays are always identical for each case. Their length varies in proportion to the mass of the radiating body. Thus for a few grams we shall have an RF of a few centimeters; while a methane field will emit an RF of a very great distance. To search and find this RF we have to turn around the body that emits it as does the carrier pigeon (wonderful dowser) which, before flying to its far away pigeon house makes several turns around the cage in which it has been closed in order to intercept the radiation line that connects its far away pigeon house with the cage in which it has left persistent radiation. But it is not only animal or mineral bodies that emit an RF; even colors possess one. In fact: we put on a table, possibly circular, a piece of nickel, or limestone or fabric of purple color, and we make, slowly, the turn of the table holding the pendulum in the hand. When we will pass in a certain point, that is when the pendulum will cross the line that joins those objects to the North, we will see that it will start to turn, because the fundamental ray of those three bodies is directed towards the North, as can be seen from the geometric figure 25 that we reproduce from the already cited beautiful book by Hector Mellin "La Radiesthésie domestique et agricole". This figure represents a quadrant that includes: an inner disk divided into many sectors to each of which corresponds a colour or a quality of rays, and a series of twelve concentric circular rings which, starting from the inside towards the outside, refer to the cardinal points, to the characteristics of the non-luminous radiations (from North to South on the left of the quadrant) and of those

figura 25

luminous on the other half of the disk; to the RF of simple bodies, of metals of woods, etc. etc. The colors are divided into positive and negative. The first ones are towards the South, and the others towards the North. Over these, the pendulum turns in the opposite direction to the spheres of the clock; over these it turns according to the arrows of the clock. Among the positive colors we place: yellow, orange, red and black; among the negative ones we place: indigo, violet and white. Blue, yellow and red are called fundamental colours because they are of pure origin and are not the product of mixtures of other colours. Finally from the quadrant in question we see, in summary, that:

towards the North radiate very alkaline bodies; towards the East radiate neutral bodies;

to the South radiate the strongly acidic bodies; to the West radiate the dead bodies.

In the intermediate spaces radiate the bodies that are more or less alkaline, acidic, etc. The fundamental rays are dark rays, elusive, therefore, from our visual sense, but although they are not luminous rays, they nevertheless refract through a prism and polarize. I have already said that every body has its fundamental ray always identical. And therefore the dowser that knows deeply his science and that has made himself a precise picture of the characteristics of those bodies that more commonly he searches and studies, will know also to individualize them from their RF and from the number of turns or oscillations that the pendulum will make when it will be under the influence of the RF. The number of turns or oscillations that each body makes the pendulum make is called Series. If the body is simple, after the pendulum has made a number of turns or oscillations, the apparatus will stop. The operator must, however, have the patience to count these movements with precision. If the body is compound, the pendulum will make a series of revolutions or oscillations for each component of the body, stopping at the end of each series.

However, the serial number is not the same for everyone and therefore each one must find it for himself and use it as a base. Good dowzers count the turns letting the pendulum rotate until it becomes immobile. Others, less sensitive, slightly shake the pendulum, after each turn, to obtain an oscillation and wait, then, a new turn: and so on until the end of the operation. For example, on the water the best dowzers obtain 7 negative turns (that is contrary to the course of the clock spheres) all in the same direction. Others, instead, obtain 7 negative turns, followed by 7 oscillations, but, both for the former and for the latter, the number of successive or fractional turns represents the serial number. On clay, for example, the pendulum turns 3 times in succession, negatively; or each turn is followed by an oscillation. In the table, taken from that of the Russian scientist Mendeleef (1864), I transcribe: in the 1st column, the progressive number; in the 2nd the name of the body; in the 3rd its atomic weight; in the 4th the RF direction; in the 5th the serial number. To this list, taken from the Manual of Radiesthesia by the often cited Lacroix-à-l'Henri, are added these other bodies, as described by the aforementioned Author:

Liquid crude oil 45° NO series 22.

It attracts the pendulum that seems to move in an oil bath. Very clear sensation even on paper.

Solid petroleum (bitumen) 45° NO series 22.

Petroleum gas (methane) 45° NO series 21.

Wine 60° NO.

The figure in the series varies according to the degree of alcohol.

Liqueurs 75° NO

The figure in the series varies according to the degree of alcohol.

Summing up: the RF is a ray of physical order, proper to each body and oriented. It gives the serial number of the body (number of revolutions or oscillations) and its length is proportional to the mass of the body. The Brochenin gives us, instead, another list of series orientation. Before going into the country in search of one of the bodies that one wants to find, it is good to establish, at home, and by means of a sample of the body itself, which is called a witness, it is good, I repeat, to establish a priori its RF and its serial number. But besides the RF we have also the solar ray (RS) which is also of great help in the dowsing researches. It is the one that connects the sun with the body on which it operates, also through the clouds, and also, for a certain time, after the sunset or before the dawn. Practically it is confused with the luminous ray. But since the dowsing RS falling on a smooth body is refracted and almost repelled towards its source, the sun, it can be considered double: 1st ray of sun coming from the sun; 2nd ray returning to the sun. Finally we have a third ray called Capital Ray (RC) so called because it goes from the object to the operator's head. By head we mean: the eyes and the brain. Abbot Mermet says: "As the stars look at us with a luminous ray, all bodies look at us with a dark ray. Every body, vibrating in all directions, constantly strikes every man with the jet of its black waves. It is they that come to us and not something of us that sets out in search of them, for we are but a receiving station." But this condition of ours occurs when we do our dowsing work. We receive and we don't use this RC that when, only, we want it. So it becomes, almost, what could be called: "mental orientation". Therefore, if the Dowser decides to receive the messages of the underground, he is enveloped by the whirlwind of vibrations of all the bodies around him. But he, by his will, fixes himself upon a particular search: oil, methane, water, iron, etc., and then his circuits become attuned, harmonized with those radiated by the body sought. Therefore, the efficacy of this capital orientation, which is also called intentional fluid, is immense, because it is through it that the operator gets in touch (I would say almost) with the body he is looking for.

Summarizing what I have said so far about these rays, and for greater clarity for the reader, I will say that: the RF belongs to the body to be searched for and is directed towards one of the cardinal or intermediate

points; the RS connects the sun to the object: this makes it possible to read the angle formed between this ray and the RF; the RC goes from the object to the eye of the operator.

figura 26

From fig. 26 the concept expressed above will perhaps appear more evident. We have an underground body that we want to find. The RF starts from it towards North, but the RS falls over it and forms an angle with the previous one. Finally we have the RC that with the other two serves to identify the position of the prospected body and its nature.

Chapter X

Attraction, repulsion, polarity

As everyone knows, attraction is that force which tends to push, reciprocally, some bodies towards each other. Attraction can be magnetic (like that exerted by a magnet), it can be physiological or sexual (like that found between two beings of different sexes) and can also be simply psychological or spiritual: in this last case we have what we call sympathy. The opposite of attraction is repulsion. Now, these phenomena exist in all Creation, and we see them manifested from the lowest elements of which it is composed, down to the great Planets that sail through the infinity of space, all following their eternal and immutable course. Examining the solar system, we notice that it is made up of a certain number of major planets, minor planets and satellites. Among the former we have: Mercury, Uranus, Neptune, Saturn, Mars, Jupiter and the Earth; among the latter: Juno, Vesta, Ceres, Pallas. As a satellite of the Earth I shall mention the Moon. Now some of these planetary bodies turn in one direction and others in the opposite direction; some are positive; Jupiter and the Moon are negative; Saturn, instead, is bi-magnetic. All the movements of the stars are due to the great law of attraction from positive to negative, in dependence, indeed in function, of the electric state proper to each of them and deriving, undoubtedly, from their mineralogical nature. Thus the dominant minerals in the Sun are gold, radium; in Saturn, lead; in Mars, iron; in Venus, copper; in Earth, barium; in Mercury, cinnabar; in the Moon, silver; in Jupiter, tin, etc. This would explain the reason for the reciprocal influences of attraction and repulsion which they exert upon each other and which are proportionate to the exchanges of energies which take place between them. To cite an example, I will remember that Venus receives twice more solar energy than the Earth. Coming now to speak about the polarity of the cosmos, we can summarize it in the following way:

Stratosphere, negative (-); Atmosphere, positive (+);

Earth: northern hemisphere, negative (-);

Earth: southern hemisphere, positive (+);

Lithosphere, that is the Earth's crust, 60 km thick: it is predominantly negative, but with positive points;

Pyrosphere, i.e., internal mass of the globe, in fusion, positive; Barisphere, or central core, positive.

The positive points of the Lithosphere are the Volcanoes and the regions rich in minerals. The Pyrosphere is composed of great masses of metals in fusion, while the Barisphere has them in less quantity, but of much greater weight. I have thought it well to expound the above in order to show how all that governs Creation, under the supreme dominion of God, who is its Maker and King, is that admirable equilibrium between attraction and repulsion, between the positive and the negative, which we may define by the word harmony. And to descend from the highest complexes of the Universe to its least expression, that is to say, to the atom, we find in it the central nucleus (protons) which is positive, while the corpuscles which revolve around it, like the Planets around the Sun, are negative. It is, therefore, by virtue of the attraction of two opposite dominant signs that the planets gravitate around the Sun, the satellites around the Planets, the electrons around their nucleus. This attraction due to similar contrasts of forces, is perhaps that which makes white harmonize so well with black; silver with iron; male with female, man with woman. And it is to the latter that I wished to arrive by means of the long disquisition which I have decided to make in order to clarify the fundamental concept of this theory. Many learned authors affirm that the happiness, or not, of a married couple resides entirely in their polarity. For example, if they have the same sign on

the same side, the union is not happy; if, however, they have the opposite sign on the same side, then they are attuned and every good wish is for them. To carry out this investigation it is enough that one of the two spouses, or fiancés hold suspended the pendulum in front of him, and then in front of the other, at about the height of the heart, first on the left side; then on the right side. If the pendulum turns, let us say to the right, both in front of the left side of the man and of the woman, the signs will be equal and therefore will indicate repulsion. This investigation can also be carried out with the pendulum on the photographs of the couple whose conjugal life is to be known in advance. I do not want to assure anyone that this method is infallible, but from several observations made, everything leads me to believe that at least 75% of the cases it responds perfectly. In any case, the test is so simple that it is worth doing. On the subject of attractions and repulsions, I will transcribe here the results of some studies made on the subject by Mellin (op. cit.).

The bull and the turkey (+) violently manifest their aversion to the colour red (+) while the frog (-) seeks this colour. The pear tree (+) is a friend of the rosebush (-); but the rosebush is harmful to the apple tree (-). The phylloxera (+) lives well behind the vine (-). A man dressed in black (+) feels attracted by a woman dressed in blue or white (-), while he will feel rejected by one who is dressed in red (+). Conversely, a man dressed in blue or white (-) will be attracted to a woman dressed in yellow, or orange, or red or black (+). Wheat and sugar beet (-) prefer a moist clay soil (+) and positive fertilizers, such as calcium cyanamide, ammonium sulfate, and mineral phosphates (+). Rye (+), on the other hand, desires a silty-calcareous soil (-) and fertilizers such as slag (-).

All this problem of polarity that we find in every part and in every form of creation, from the stars to the minerals, from the vegetables to the animals, from the colours to the humans has a great importance also in the daily practice of our life. The pendulum can be of great use to us in this research and in its applications. For example, dear and patient reader, you have to deal with a person you do not know and whose true feelings, honesty,

intelligence, etc. are unknown to you. Well, it is very easy for you to know how to regulate yourself. If you have them, take a photograph of him, or a piece of writing. Then, on a piece of paper, write down the question to which you want an answer; for example: "Can I trust Mr. Tale?" or "Is Mr. Tale honest?". Concentrate and keep one hand either on the writing or on the photograph of that person, while with the other hand you keep the pendulum suspended. If it turns, the answer will be positive, if, however, it oscillates, the answer will be negative. I have done this experiment countless times for myself and for other people, and the answers have always been precise and true. I only regret to have known too late the pendulum and its infinite applications, because I would not have experienced perhaps all the disenchantments and all the misfortunes that have embittered my life.

Chapter XI

Initiation to dowsing

The elementary and orderly treatment of so vast and complex a subject as that which I have set myself to expound to my readers, I fear exceeds my modest strength; for one of the greatest difficulties I meet with in this work is, among others, that concerning its best and most rational development. I would have liked to give it a progressive order and to lead the reader step by step, degree by degree, towards the conclusion by making him cross successively all the plans that compose the building of this science; but I have realized that, at least for me, this is not possible because many elements cross each other, intertwine and, from time to time, precede each other, so that to follow a precise order of didactic development is almost impossible. It would be necessary to expose them simultaneously. But how can this be done? Therefore I beg the reader's pardon if my writing seems to him disordered. For example: the present chapter should have been one of the first: nevertheless I could not begin to indicate the way to follow, to become a good dowser, if I had not first given to the scholar some instructions and some indispensable clarifications to understand what I will now expose. I have already spoken of the means and instruments to be used in dowsing and of the dowsing faculties or possibilities of humans. Now I will try to teach how these last ones can be developed and how the first ones must be used. Obviously the dowsing sense must be found in every individual, and perhaps it will be the more developed the more the individual will be less advanced or refined. Therefore I have already cited the examples given by the carrier pigeons, and those given to us by the animals that present the great cataclysms, earthquakes, etc., and by the animals that present the great cataclysms. But, as if these were not enough, I shall relate a fact which has often been checked by hunters, scholars, and naturalists, both in Africa and in certain desert regions of South America. To find the dens of large beasts they hunted, the explorers used the pendulum and with it they were able to identify them, but when they arrived on the spot, the animals had, always, a short time ago dislodged because they with their dowsing intuition had anticipated the arrival of the hunters. In man this intuition is much weaker and therefore if he wants to take advantage of it, he is obliged to cultivate it, to develop it as he does in every

other field of activity or science, not losing heart if, at the beginning, he encounters difficulties and if he has failures that happen to everyone. Vice versa should not get excited or believe to be perfect, if it will get from the beginning some good results that may depend on causes unknown to him. For all training exercises, of course, would be preferable to the open countryside, but I know that not everyone can have this comfort and, therefore, we will limit ourselves to a garden, a courtyard, to end, perhaps, in the only ... bedroom.

Exercises with the wand. - Go into a garden or a courtyard through which passes an underground water pipe of which you know the precise location and direction, because the rubbing of the liquid against the walls of the pipe will constitute the field to be measured. Then you will walk slowly towards it (orthogonally to it) holding your hairpin in your hand, and you will go beyond the pipe itself by a few meters. Four cases can be given:

1° - that your hairpin straightens before you have reached the vertical through the tube. In all probability this would demonstrate an effect of autosuggestion manifested in you;

2° - that your stick straightens up after you have passed the conduit of 25 or 50 cm or even of 1 m. This would be a good indication for you, because it should induce you to apply yourself to this study. This would be a good clue for you, because it should induce you to apply yourself to this study;

3° - that your stick rises when it is precisely on the vertical of the tube. Do not be satisfied with only one such test. Pass and pass over the same pipe to repeat the experiment and to verify if you always obtain the same results;

4th-that your wand give no sign. Do not be discouraged by this, but persist in trials and training. To possess a late perception does not exclude the possibility of having one.

If you don't have a garden or a yard, go to the kitchen and let the water flow from the tap into the sink. This movement of the liquid will be enough to release those vibrations that will act on your wand of which you will present the tip above the place where the water will flow.

Let us pass to another exercise: place on the ground a piece of metal or of any mineral so that it receives directly the rays of the sun. Introduce the point of your wand into the solar ray, and you will see that it will act and move independently of your will. You may also renew this experiment by using, instead of the sun's rays, those coming from an electric lamp of a hundred watts. These experiments should not last more than five minutes each, and not more than one hour, at the most, per day.

Exercises with the pendulum. - The above experiments can be done more easily with the pendulum than with the rod, because the latter does not respond to all those who use the pendulum. But even with this one requires constancy. We know of people who needed two months to obtain the first results. At the beginning of your pendulum exercises do not try to impose your will on the small instrument to make it turn or oscillate, because you would fall into errors: but be content to do pure and simple Dowsing letting it work freely. For these preparatory and training exercises you will have to use:

- of a horseshoe-shaped magnet;

- of a pocket-size flashlight;

- of a compass;

- of a curious Chinese design called Yn Yang which I will tell you about at length later.

Magnet. - I have already explained what a magnet is and what its characteristics are. Now place a magnet on your table, in front of you, with the tips facing right (fig. 27). If you slowly bring your pendulum closer to the point closest to you, you will see that your pendulum (preferably made of wood, ebonite, fibre or ivory, but not magnetic), having arrived at a distance of about 1 cm from the aforementioned point, will oscillate longitudinally a b with respect to the branch of the magnet, while on the other you will see it oscillate in another direction: c d. The first point of the magnet will therefore correspond to the North and the other to the South. Each of these will therefore give the pendulum a different oscillatory movement but a third movement, this time rotating and almost always in the opposite direction to the hands of the clock, will occur in the semicircle formed by the magnet. Finally, if you bury your magnet at a depth of a few centimetres in a container filled with earth and if above it, at a distance of about 10 centimetres, you suspend the pendulum, you will soon see that it will begin to rotate in the direction of the hands of the clock. Later in practice you will find that most of the bodies buried in the ground which make the pendulum turn in the latter direction possess a certain magnetism.

figura 27

And since you are working with the magnet, you can immediately experience the effects of the remanence of that impregnation of which I have already spoken. In fact, if after a quarter of an hour or so that the magnet is on the table, you suddenly take it off, and if you make the pendulum slide on the exact place where the magnet was just before, you will see that your apparatus will reproduce exactly the same movements that it performed on the magnet itself. Why is this so? Because it has left its remanence, its vibrations, in the place it occupied before. Thus you will be able to verify a first phenomenon of remanence.

Electric pocket battery. - In these batteries, the positive (+) pole is always located on the shorter tab (fig. 28) and the negative (-) on the longer tab. Here, too, the pendulum will act in the identical manner with which it worked with the magnet, i.e.: on the positive side it will oscillate longitudinally according to a b; on the negative side it will oscillate transversally according to e d; and between the two we will have the rotating movement to the left.

figura 28

Compass. - Here we have a different behaviour of the pendulum, since it will oscillate transversally to the magnetized tip of the needle (fig. 29) and will turn leftwards on the opposite tip.

figura 29

Yn Yang. - Now I am going to talk about a Chinese symbolic drawing that dates back to about 3000 years B.C., which is called Yn Yang and which gives us the same magnetic field as the compass. How? Why? No one will ever know the answer to these questions. And yet it is a certain fact, a perfectly controllable phenomenon, that when we suspend our pendulum over this design, we must, after a few moments, exclaim with the immortal Pisan: "Yet it moves". What is Yn Yang? Better than any description in words, a graphic reproduction is worthwhile (fig. 31). To draw it, trace the diameter of a circle (fig. 30) and divide it into 4 equal parts A B - B O - O C - C D. Then, successively centering in B and in C, connect the described semicircles, both among themselves and with the circle that encloses them. Finally we pretend in black one of the two resulting figures, drawing in the center of the largest part of it, the eyes, as seen in Figure 31. These aforesaid two figures, which have the form of two large commas or, better, of two fish clasped one against the other, the tail of the one encircling the other.

figura 30

head of the other, represent, according to the orientals, the two principles and are known with the names of Yin that means darkness (black part) and Yang that means light. These represent the negative forces and the positive ones. But the parallelism doesn't stop here, because Yin still means the water, the heat, the female, and Yang in its turn means the fire, the matter, the cold, the male: in short the Yin Yang represents, summarizes everything. It constitutes the universal binomial with which all the material and spiritual problems of life are resolved. We, on the contrary, do not know nor we can answer to the questions that above we have asked ourselves and how it is that this figure (that we can make in cloth, etc.) acts as a dowsing pendulum similar to the compass or better to the needle. With these reproduce the drawing on a cardboard, on a table or on any other plane. Place the pendulum on the wide side of one of the two and then on the wide side of the other. You will see that it will turn to the left on the head of the white part, while it will swing from a to b and vice versa on the opposite, or black, part. This shows that the black part corresponds to the point of the magnetized needle and the white part to the negative.

figura 31

figura 32

In Korea the Yn Yang is quite different. It is called Tah-Gook and is the Korean national emblem; but instead of having black and white for colors, it has red (royal color) and turquoise (color of dawn). So for Koreans Tah-Gook means: "Empire of the Morning" (fig. 32). The Japanese adopt a symbol with three heads and three colors (fig. 33). The colors are: red, turquoise and green. They consider it as a real talisman and with superstitious respect; so they always wear it sewn in the sleeves of their "kimono". It has the shape of a small medallion and the size of a hundred lire coin.

figura 33

Another symbol that is very widespread in China is called Pa Koua, which is nothing more than the Yn Yang surrounded by three special circles that form eight different diagrams that have a profound philosophical meaning, which is too long and too complicated to explain here. At most I will limit myself to briefly mentioning them.

One of the great masters of Chinese philosophy, Fuh-Hi (3332 years B.C.) established that the Unlimited produced the Great Extreme, which generated the two "Principles from which the four Figures were born". From these the Chinese deduced the eight diagrams of Fuh-Hi. How to interpret all this terminology? Some have thought to translate the Limitless into Infinity; the Great Extreme into the Supreme Divinity; the two Principles into Good and Evil; others into Male and Female; others into Day and Night, or Light and Darkness. And, in the four Figures, some wanted to recognize the four cardinal points, others the four seasons, etc., etc. However, it is evident that this symbolism seeks, I would almost say, to

connect with our religious theories and to identify with our catechetical criteria: the Unlimited is the Infinite; the Great Extreme is God. But how did the Chinese represent all this? With simple lines. Thus the two Principles were represented as follows:

From these two Principles they deduced the four Figures by alternating the groups of the two Principles:

Finally, by placing each of the four Figures under each of the two Principles, they formed the following eight diagrams:

According to Lacroix-à-l'Henri these lines are the letters T and M of the Morse telegraph code and the diagrams above are ingenious combinations of these letters.

figura 34

However we want to interpret them, we find those diagrams drawn in the octagonal band that circumscribes the Yn Yang (fig. 34); in which figure are to be noticed the extremities of the eight rays corresponding to the cardinal points and to the intermediate ones and the position of the head of the inner figure placed on the axis N - S. Now this drawing, as I have already said, can serve us as much as the compass for our dowsing exercises, with the pendulum, which can be carried out both day and night and especially for the diagnosis of the illnesses, as we will see further on. After having made constant and persevering exercises for some months (either alone or under the direction of an expert in the matter) the pupil will have to continue them in the country always, however, guided and instructed by someone who already possesses all the technique of this science, because he will meet, as in every human thing, many difficulties to overcome, many abstruse problems to solve.

Chapter XII

Rotations, oscillations, Witnesses, impregnation and disimpregnation, identity

As we know, the pendulum makes various movements during its work of receiving the mysterious waves and irradiations of the bodies for the study or research of which man employs it. These movements are, I repeat, rotatory in two directions: parallel to the operator's chest or orthogonal to it; or better still, from east to west and vice versa, and from north to south and vice versa. The right-hand rotation, i.e. according to the course of the clock spheres, is always positive (+) and affirmative; the opposite rotation is always negative. In the same way, transversal oscillations (E-0) are positive; those from North to South are negative (fig. 35, a, b, c, d).

Examples. - If we place on a table two small bottles containing: one of pure, drinkable water and the other of unhealthy water, and if we suspend the pendulum over them, we will see that on the bottle of pure water it will turn to the right (like the balls of the clock), and on that of unhealthy water it will turn in the opposite direction. Let us place on the table three eggs, well washed, and let us pass the pendulum over them. Three different cases can be given: that above one (fig. 36) the pendulum turns to the right; that above another it oscillates transversally to its longitudinal axis (fig. 37) and finally that above the third it oscillates parallel to the aforesaid longitudinal axis (fig. 38). The responses will be: in the first case that the egg is fertilized and that a female will be born from it; in the second case that the egg is not fertilized; in the third case that a male will be born from the fertilized egg.

figura 35

Mellin advises, however, in this connection to follow a precise method. He says to arrange the egg to be examined not in any position, but so that its longitudinal axis coincides with the North-South axis, with the narrowest point towards the North. Then the pendulum is passed over the egg, giving it an oscillating movement. After a few minutes of waiting, the pendulum will either continue to oscillate, turn to the right or turn to the left. If it will continue to oscillate, the egg is not fertilized; if it will turn from right to left the egg contains a future hen; if it will turn from left to right, we will have a future cockerel.

A good food will give us, with the pendulum, positive rotations, while a bad food will reveal itself through a negative rotation or oscillation. The dowsing practice is based, almost all, on the observation of the pendular movements and on their interpretation.

Witnesses. - These are called those bodies which one holds in one's hand, or which one touches with one's hand, and which are identical with the bodies one seeks or studies. They are almost indispensable; I do not say that they are absolutely indispensable, but it is always very useful to make use of them when one has use of them. A witness may be a piece of metal corresponding to that which is being sought; it may be a bottle of water, wine, oil, etc.; it may be a leaf, a flower, a seed; it may be the feather of a bird; and it may be, finally, a photograph, a writing, or any object of a person on whom we are carrying out our investigation. Doing research in the country, the witness should be held in the hand that holds the pendulum, and if you operate with the wand, in the hand that holds the positive branch of the hairpin. When working on the table, however, one can place the witness on the table and hold only one finger on it. Some, according to the method of Viscount Henry de France and the Abbot Mermet, use empty pendulums, inside (fig. 8 e) in which they introduce a small quantity of the body to be searched. It is natural, however, that these pendulums must then be disimpregnated by the emanations emitted by the body they contained: and this to avoid the effects of the remanence due to the impregnation of which I have already spoken. As we are dealing with liquid substances, the pendulum destined to contain them can also be a simple phial. The pendulum will forcibly turn in the sign of the polarity of the body being studied. For example, if we look for clay, of which we have a sample in our hands, and if we walk through a zone of calcareous formation, we will see that the pendulum will continue to oscillate until we find ourselves above a deposit of the mineral similar to the witness (clay) that we hold in contact with the pendulum. As soon as we are at this point, the pendulum will begin to swing in a negative direction. As we have seen in fig. 25, limestone has a negative sign. Remember that the pendulum will always rotate according to the same sign of the body: if the body is negative, as we have seen, the

pendulum will rotate in the negative sense; if the body is positive, the pendulum will rotate in the positive sense.

Impregnation, disimpregnation. - We already know what is meant by impregnation. Every body (vegetable, mineral or animal) undergoes this phenomenon or this law of induction. Thus a case will retain the radiations of the jewel it contains; a glove, any garment, will be impregnated with the magnetic radiations of the person who wore them; but with this difference that, as long as the aforesaid garments are worn by the person, they will have the same sign of him; but after he has removed them from himself, their internal charge will be modified and their polarity will become the opposite of the external one of the individual who wore them. In short, here we verify Lenz's Law for which we know that if we approach a piece of iron to a magnet, this will behave, for influence, like the magnet itself because it will have undergone the electro-magnetic induction: in the iron will be formed a current of polarity opposite to that of the inducing electro-calamite. But when we remove the induced iron, it retains for some time the current of the same sign as the inductor. This is the case with clothes, which are positive on the outside and negative on the inside, or vice versa, according to the sex of the person who was wearing them. And to be more precise I will say that:

the man's jacket is negative on the inside and positive on the outside;

the woman's blouse is positive on the inside and negative on the outside.

The same applies to any other male or female garment.

This shows how the mysterious emanations directed from our bodies to our clothes act on the pendulum like the direct irradiations of our own organisms. If, therefore, we can establish the identity of a person by the mere examination of a piece of cloth that covers him, our researches are much easier when we can carry them out upon a hat, a drop of blood, a bit of saliva, a photograph, etc. So it is still explained why the vital radiation of the Egyptian mummies was found after 4000 years. Likewise, it explains why a painting retains the radiation of the artist who painted it. The pendulum is the most terrible weapon for discovering fakes, make-ups and retouches of real works of art. But if the leftovers due to impregnation are so often useful to us, they sometimes become harmful because of the errors to which they give rise, because they affect not only the clothes, but also the pendulum and the stick and even our nervous system. This is the reason why after each important operation of study or research of a given element, the operator and his instrument must, as they say, discharge themselves of the induced emanations, both for the health of the dowser himself and not to compromise the result of following operations.

How to get disimpregnation?

The means indicated by various authors are numerous and also quite simple. According to some, it is enough to blow hard on the tip of the pendulum or of the rod, while they are still holding them, as soon as the operation is over, because in this way the apparatus and the operator are discharged. Others plunge their hands into the water, or grasp a stone, a brick, a piece of metal, or better still, place their palms against the ground.

Identity. - Let us suppose that we are examining two fragments of rock or two piles of earth which we have before us on the table. While we hold the finger of the free hand, stretched like an antenna in the direction of the aforesaid bodies, with the other hand we hold the pendulum suspended over them. If the instrument turns over both in the same direction, we shall say

that there is identity between the two bodies examined. Thus for the examination of coins and other materials.

Tuning. - It is said that two or more bodies are tuned to each other when, arranged on the axis of the Earth's magnetic field or of a horseshoe magnet, the pendulum, passing over the bodies themselves, will turn in the direction of the spheres of the clock. For example (fig. 39): we place a mound of clay-humiferous soil on the axis of the magnet and, at about thirty centimetres from the aforesaid soil, we place another mound of calcium cyanamide.

figura 39

Over each of these materials we pass with the pendulum. We will see that for both it will turn in the same right-hand direction. This means that the two bodies are attuned and that, therefore, cyanamide is a fertilizer suitable for clay-humiferous soil. If we replace cyanamide with another fertiliser (fig. 40) that is not suitable for the above-mentioned soil, we will see that the pendulum will turn in the opposite direction; for example, if we replace sylvite with cyanamide.

figura 40

With this system we are able to distinguish a false pearl or diamond from real ones, and above all we can establish which colours are most suitable for the upholstery of a room or for our clothes, and which foods or

medicines best suit our organism. On this point I will return at length when I speak of Radiesthesia applied to medicine.

Chapter XIII

Eye radiation - Orientation without a compass

The radiating power of the eyes is unknown to the great majority of men. Yet the eyes are very powerful transmitters of very powerful waves and constitute, therefore, an indispensable means of communication between the operator and the body or element he is searching or studying; or, to say better, between the nervous and cerebral system of the dowser and the aforesaid body or elements. And here it is why we give so much importance and we place so much care to direct our looks, in all our operations, toward the matter we seek. But not all the eyes act equally on the pendulum. I remember, in this connection, that one evening, in the house of a mutual friend, I and two very skilful physicians, subjected ourselves and several persons present to the experiment, to the examination of our eyes executed with the pendulum. The conclusions were astonishing for the precision of the responses. For the little apparatus revealed to us that a lady we examined had weak sight in her right eye, and that in her left eye she was almost blind, although nothing could be seen out of it. And this was perfectly true. Another lady, however, had both eyes perfect and very radiant, so that the pendulum swung wide and fast over each of them. To one of the two doctors, as to myself, suffering from hypermetropia, the pendulum did not spin on the eyes, but oscillated continuously changing direction and, that is, following the course of the two optical axes: vertical and horizontal.

Orientation without a compass. - Let's suppose that we are lost in a plain or in a forest on a cloudy day or at night, without being able to use either the sun or the polar star for orientation. How can we find North or South? We have, however, with us our prodigious pendulum, which will immediately get us out of trouble. We take it with one hand and give it any oscillatory motion while with our thoughts we want to find, for example, the North-South line. After having given the first impulse to the pendulum, we hold the arm still but without rigidity and wait. Little by little we will see that the apparatus will take spontaneously, with its oscillations, the direction we

want: that is from North to South. But where will the North be and where the South? Very simple. Put a piece of iron or a set of keys in the hand that holds the pendulum, and turn it around with the other arm extended so that the free hand serves as an antenna. When this is directed to the south, the pendulum will turn in a positive direction, while on the other cardinal points it will only oscillate. And this because we had iron as a witness. Other bodies serve to identify other cardinal points, as I summarize below:

for the North, use nickel, or clay, or a purple cloth;

for the East, use glass, or silicon, or a green cloth;

for the South, use iron, or clay, or a red cloth;

for the West, use lead, or humus, or a grey cloth.

Causes of errors. - In spite of all that I have tried to explain, more or less well, up to now, I do not want people to believe that the operator of the pendulum or of the stick is infallible. No, far from it! Especially beginners often make big mistakes; but these mistakes depend on them and not on the small instrument they use. One of the main causes of mistakes is the desire to obtain a positive result quickly. Instead, the dowser should not be in a hurry and should eliminate the action of his own will during his work. Other causes of errors are: a pendulum not suitable for the operator or for its length, or for its weight or for the material with which it is made; fading; autosuggestion; physical or psychic tiredness; leftovers; anger or other psychic perturbations; the presence of adverse people; the color of the clothes; the proximity of some jewels, etc. For all these reasons the dowser

must, preferably, work alone, or at least far from the others: he must work calmly, with great serenity, completely abstracting himself. While working at the table he should never keep his legs intertwined and he should keep his free hand resting on the table with his fist closed without effort, unless he uses it to lightly touch a witness. The table should be kept clear of all objects other than those under examination.

Finally, I once again recommend combating autosuggestion, which is our worst enemy. In operating we must not continually think of what we wish to find, for in that case our apparatus will erroneously indicate its presence to us at every step. Thus, if we go in search of a lignite deposit, for example, we must, before beginning the search itself, think intensely of the lignite, and then we must put ourselves in a state of complete abstraction, almost of unconsciousness; we must transform ourselves into an automaton that walks mechanically with its pendulum, or with its hairpin in its hand, without trying in the least to influence them. These precautions are fundamental and of capital importance.

Most favourable times. - According to Mellin the most favourable times for working in the country are: from 7 to 11 a.m.; from 3 to 5 p.m. and from 8 to 11 p.m. because at these times the reactions manifest themselves more energetically; especially if the sky is somewhat cloudy. Also after the rain it is good to work because it will have destroyed the dust suspended in the air, because everyone knows that the dust, electrifying itself, disperses the atmospheric conductivity, diminishing the faculty of reception of the dowser and constituting a cause of fading.

Chapter XIV

Harmful waves and beneficial waves

Until a few years ago no one thought of this; and if anyone had spoken of harmful or beneficial radiations, he would certainly have been regarded as a poor lunatic, always because man believes and admits only what he knows or thinks he knows. For most of our fellow-creatures the world ends where their horizon ends. Rare are the Columbuses who, beyond their horizon, glimpse other lands, other regions and other horizons. I do not speak, then, of those who restrict their cerebro-visual field even more to their study room, to their desk and, perhaps, to the miserable sheet of paper that they read or that they fill with their writing. And of these gentlemen, soaked in their old doctrines, confident only in their knowledge, there are many! Well, it is not for them that I write these pages, which would attract their prayers, their condemnation and their anathema. But I hope that, among the many who will have had the courtesy to accompany me on this little journey through a new scientific world, I hope that some will feel at least that curiosity which every individual feels when he visits a country new to him for the first time; and I hope that, from this natural curiosity, will spring the wonder and interest that will lead to the discussion and study of these new theories. When, some time ago, some friends, whose knowledge, intelligence, and seriousness I highly esteem, spoke to me of Dowsing and its wonders, I was astonished, but did not at all reject their ideas, or deny the possibility of the facts which they quoted to me in confirmation of their theories. I have a rule never to deny anything a priori; but I always want to examine and discuss matters thoroughly, because it is only in this way that I think man can afterwards express his opinion with some knowledge of the facts. There are only the dogmas of the Faith which I accept without discussion because the duty of a Christian is to believe them. If I argued about them, I would no longer have that blind faith that constitutes the foundation of Religion. Therefore, after passionate and exciting discussions with the aforesaid friends, I began to read some learned and interesting works which expounded the subject at length (which I quote in the final bibliography) and to meditate upon them, making, on my own account, proofs and reproofs which confirmed to me the truth of the facts which, in the publications consulted, I had read. Therefore, rather than my own

words, which may be of little value, I will quote those of eminent men who have devoted themselves for a longer time and with greater competence to these arduous and severe studies. And now I will come to speak of the harmful waves. What are they? Do they really exist? Yes, unfortunately, noxious waves do exist, and they are those which emanate not only from external bodies or substances, but also from subterranean ones, acting with great and harmful influence upon our organism. Among the elements that emit such harmful radiations I will mention:

- Underground currents of unhealthy water;
- Sewers;
- Old wells and cisterns filled in;
- Deposits of certain minerals such as: lead, mercury, etc;
- Buried bodies;
- Houses impregnated with the emanations of cancerous people who have lived or died there;
- Cabinets that have contained clothing or objects belonging to infectious disease patients;

- Egyptian statuettes or those of ancient peoples devoted to bloody rituals (Mexico); some Indian simulacra, etc. etc.

Now, while it is possible to destroy certain evil radiations of external bodies, such as furniture, statuettes, etc., either by powerful disinfections or by the removal of them, it is not so easy to eliminate those coming from the subsoil, which are so important for our health. In fact Radiesthesia has taught us that it is enough that under a house, under a room and above all under a bed there is a fracture of the ground, a small course of water or a lode of mineral, for the inhabitants of the house to suffer a nefarious influence on their health. The pendulum is the indispensable aid in establishing the presence of harmful waves, because it will always know how to indicate them to us by its negative movements. Before building a house or a barn it is always good to make sure, radiesthetically, if the area is healthy, free or infected. Sometimes the position of the bed is enough to allow, or not, a quiet rest. This may seem strange, inconceivable; yet it is absolutely proven by hundreds, I will say thousands of experiences. According to the orientation of the bed, it should be so arranged that the head of the sleeper is in the North and his feet in the South, so that his body is traversed from one end to the other by the magnetism of the Earth, which is an immeasurable element of physical well-being, the value of which we do not rightly enough appreciate. The human body may be regarded as an electric accumulator which, during the period of rest in sleep, recharges itself automatically. By sleeping peacefully, that is to say, with complete rest not only of the limbs, but also and especially with that of the spirit, you will derive all the possible benefits: you will eat less, but you will assimilate more and your strength will increase considerably. But to obtain these results it is necessary that you sleep in a North-South orientation. If your bed is arranged or oriented differently, you may believe that you are sleeping soundly, but only in appearance, because your health will suffer the opposite effects.

Since I am speaking of the bed, it is also very useful for you to know whether the material on which you sleep suits your organism, that is, whether it is better to rest on a mattress of wool rather than of vegetable hair, whether it is better for you to have a pillow of wool or of feathers, etc. Take your pendulum and question it in this way. Take your pendulum and question it in this way: place the mattress or pillow before you, and between you and the aforesaid bodies hold the pendulum suspended. The pendulum, turning to the right or to the left or oscillating, will give you a positive or negative answer. But, to return to the harmful waves, I will say that their effects may often be avoided simply by moving the bed. Abbot Bourdoux mentions in his very interesting book several cases of persons who could not rest at night in their beds and whose health was continually deteriorating, until he or other skilled dowsers intervened with their pendulum and found the cause of the evil, which always consisted in this: that the beds were situated over a sewer or over a channel of unhealthy waters which were identified with the pendulum itself. Besides, without going to look elsewhere for examples of what I have here narrated, I will say that I myself have made a long experiment. Given the orientation of the house in which I live and the arrangement of the rooms that make up my

apartment, I had placed my bed in the middle of the room, with its head against one of the walls (fig. 41) so that it was cut diagonally by the North-South line. At night I slept, yes, but I didn't rest, because sleeping is something else, resting is something else. In fact, in the morning I got up more tired than I was the night before, when I went to bed; my bones seemed to be broken, my eyes were burning, my head heavy, etc. etc. I attributed all these phenomena to the excessive work I had been doing for years. I thought that my daily 14, 16, and even 18 hours of intense work were what was breaking me down so much. And I was wrong, because my studies on dowsing enlightened me on the subject. I changed the position of the bed (figure 42) placing it on the North-South axis. The beneficial effects of such a change were almost immediate because I no longer feel any of the phenomena that I complained of at other times and I always get up early in the morning, perfectly rested. It is true that with such a disposition of the bed, my very modest room has a strange aspect; it is true that my friends, goodness me, mock me calling me a maniac. But this does not matter to me, especially as some of those who used to make fun of me have since come to confess that they have followed my example, and that they actually found it much better. And since the function of sleep is as important to us as that of nutrition, I do not see why we should not be as concerned about that as about this. This is to show that there are truly pernicious areas. The Chinese and the Japanese know this too, and for thousands and thousands of years, as I have said above, before building their house they have carefully studied the land where it should stand. And how do they study it? By means of Dowsing which they have known since about 3000 years B.C. After that, when we see the repetition of the same disease in the same house, why not resort to Dowsing in order to know its origin? It is so cheap! Let us examine the case of such a dreadful and frequent disease as cancer. Some devotees of this new science believe that it may be attributed to the house which is situated in a ground, from the subsoil of which emanations radiate, favouring the evil in question. It seems to be proved that this is indeed true; but this does not mean that a house in which a cancerous person resides is absolutely a house of cancerous persons. No. In order to suspect this, it is necessary that in such a house several cases of the said disease have occurred.

Beneficial waves. - Just as there are unhealthy radiations, there are also, thank God, beneficial ones. Some of them come from minerals and plants; others are emitted by living persons. Among the bodies that emanate beneficial radiations I mention certain thermal waters, violets, chestnuts, and even deep oil deposits. As regards the beneficial waves emitted by living persons, it will suffice for me to mention those who, by merely laying their hands on a sick person or on a part of him, heal him perfectly, sometimes instantaneously. I have myself seen some extraordinary examples of this, which leave no doubt, and which certainly cannot be attributed to suggestion or autosuggestion; words with which the incredulous wish to explain every fact that their dull mind does not permit them to understand, to discuss, or to admit. By autosuggestion they believe they can solve everything: from the stigmata of St. Francis to the miracles of Lourdes. But even if we admit the phenomena of autosuggestion, we must agree that this autosuggestion constitutes a force which is unknown to us, but which is so powerful that it exerts on our organism evident, incontrovertible manifestations. And what is this force? In what does it consist? Leaving aside, therefore, to speak of healings obtained through mediumship, as is the custom today, it will suffice for me to report here a fact that Father Bourdoux tells us in the book already cited. There lived in Bordeaux (France) some years ago, a lady who noticed, one day, that in her house the flowers never withered, that the fruits did not rot and that the flesh itself never became corrupt. These strange phenomena did not fail to arouse, at first, the wonder of the lady's acquaintances; and then, as the news spread, the curiosity of some doctors who, instead of laughing at the thing, wanted to study carefully the phenomenon itself, concreting in a large detailed Memoir, printed in 1921 in Bordeaux by the Gounauihou printing house (Rue Guiraud 9), the results of their observations, their studies and their research. This Commission of experts was composed of Drs. Clarac, Llaguet, Cabanès, Gustave Geley, Marcel Soum, doctor of science, H. Pruvost, pharmacist of 1st class. Here is what these gentlemen wrote on the subject in their Report (pages 19 and 20): "The plants seem to be rapidly sterilised, they dry up while retaining their colours, and the leaves (a very important observation) always remain attached to their stems. The small animals do not undergo the slightest putrefaction. They dry up little by little, and remain, afterwards, mummified without any subsequent change, even for several years. The same is true of fish, crustaceans, and birds. Larger

animals, such as large birds and small mammals are preserved for a long, long time. While they should already be in a state of advanced putrefaction, they continue to present the appearance of recent death and do not emit any bad odor. However, after 10, 15 or 20 days, and even more depending on the season and the volume of the animal, the situation changes and a new phase begins. A beginning of putrefaction can be noted, which is just perceivable, as well as the odour which develops. There is no swelling of the animal, no internal development of putrid gases and no liquefaction. The skin tissues, i.e. those which have been most affected by the effluvia of Mrs. X... do not undergo any change. Shortly afterwards comes the third phase: drying. The tissues shrink, the smell disappears and mummification begins. It is completed and perfected in three or four, at most five weeks. From that moment the animal seems to be preserved indefinitely. The hairs or feathers remain perfectly adherent to the body; the colours are "kept as they are, and the animal remains as well, if not better, as if it were embalmed. But what is even more marvellous, is that if you submit to Mrs. X... a corpse already in putrefaction this putrefaction is interrupted and stopped clearly after two or three sittings; the smell disappears and the drying begins. When the corpse contains parasites, such as, for example, larvae of flies, these parasites seem to be no longer able to live in their environment of choice, because since the first intervention of Mrs. X..., you see those larvae quickly abandon their prey and gather around it to die almost immediately, while the corpse is mummifying". What is to be concluded from these facts? The same men of science who collegially carefully studied the case could not draw a definite conclusion from it, and confined themselves to asking the following questions:

1° What is the nature of the sterilizing agent? 2° Is it what is called magnetism? 3° Are we, perhaps, confronted with an unknown human radioactivity?

And Dr Gustave Geley thus concludes the Report he made of this extraordinary case to the Universal Society of Psychical Studies in Paris on 27 October 1921:

"We know nothing about it, but we should suppose that Mrs. X... emits an unknown force capable, nevertheless, of powerful and profound organic action. Now, we would be dealing here with a discovery of which it is sufficient to say, to understand its capital importance, that it would destroy one of the most tenacious dogmas of classical psychophysiology: that which refuses to admit the remote actions of the human organism."

Is this also a case of autosuggestion? Are the dead also susceptible to autosuggestion? People will ask me if these facts are true. I will answer in Dr. Geley's own words: "I assisted Mrs. X. for two weeks... taking all the notes". And from the religious point of view, R. P. Bourdoux tells us that two priests of Bordeaux who knew Madame X very well... described her as a devout and excessively modest person, alien to any notoriety that she escaped in every way. She herself marveled at what she did and was astonished that not everyone had this prodigious faculty of hers. And the R. P. Bourdoux narrates that one day, having gone to Bordeaux to see one of the two priests who had been summoned, and having asked him to tell him the truth about the said phenomena, that priest went to the attic and came down again carrying with him several cardboard boxes, covered with dust, in which were perfectly preserved flowers, fruits, fishes, birds and even a small cat. And they had already been preserved for more than twenty years. Well, the manual impositions that Mrs. X... made on these objects were made only at a distance of about 20 cm between her hands and the objects to be preserved, but undoubtedly she could have exercised that mysterious influence, not at a metre, not at a hectare or at a kilometre, but at hundreds and thousands of kilometres. Do you laugh, gentlemen? Yet even Aristotle said one day that the slightest movement we make with the tip of a finger has repercussions at the other end of the world. This metaphorical saying was already a dowsing statement: a science that seems to date back to the remotest antiquity. But the Bordeaux lady of whom I have already spoken, lived about 20 years ago, was unaware of the vastness of its irradiating power and never thought of making tests at a distance, all the more because modern Dowsing was, then, in its infancy and, therefore,

Mrs. X... lacked the guidance, the instructions and the training that could have made her perform other prodigies at a distance. This part of our study, however, will form the subject for another chapter.

Chapter XV

Radiation at a distance

It is undeniable that the radiations emitted by our bodies spread through the atmosphere like the sound waves of the radio. Life is but a continuous motion, a motion which perhaps has its origin in the lowest component of matter, the atom. Let us remember, however, that this presents itself to us under two aspects: chemical and physical. From the chemical point of view the atom is the last indivisible portion of matter; while, physically speaking, it is constituted by a nucleus around which electrons rotate at a fantastic speed. From this incessant, eternal motion of corpuscles almost inconceivable to our mind, derives that force which we call radio-activity which is an intra-atomic property corresponding to a spontaneous emission of energy that emits Alpha and Beta corpuscles and Gamma rays. The seat of radio-activity resides in the core of the atom (impenetrable to chemical action) which contains within itself formidable energies. Because of these energies the disintegration of the atom takes place spontaneously producing that new force which is called radio-activity. In fact we know that a gram of radium in a state of radio-active equilibrium, emits 37 billion Alpha corpuscles per second, losing half of its volume in 1590 years. But what is the fundamental character of radioactive elements? It is electricity. Well then, why could not all these incalculable movements, all these immeasurable energies be guided, routed, I would almost say, by another force which had its origin in the human organism so complex and still unknown? For we know perfectly well the anatomical structure of man. But is there only matter in man? And of this matter, so varied, do we know all the properties? Now could it not be that all these arcane forces, all these unknown waves, all these mysterious terrestrial and cosmic radiations, all these emanations of colours, minerals, vegetables, animals, etc., could it not be that they undergo laws which we do not even remotely suspect, and that they also serve as a vehicle between one body and another under certain conditions? How many questions, how many mysteries, how many unknowns are presented to us, and to which we cannot reply either affirmatively or negatively! And the eternal struggle continues between doubt and truth; between thought and reality; between science and mystery. It is admitted, indeed it is by now peaceful, that mediumistic healings are

frequent: they occur every day and, as I have already said a short while ago, I myself have checked some truly prodigious ones. Today there are, even in Italy, doctors of great value who make a bulwark with their university degree to fight the charitable and human work of those people who, endowed with such a great gift from the Celestial Power, perform cures and healings that all health professionals had declared impossible. It is not a question of charlatanism, as some people claim, only to fight against these benefactors of humanity. While recognizing that there are cases in which the results have been negative, we must confess that these negative cases represent such a small percentage compared to the positive ones, that they do not diminish the value of mediumistic care. Perhaps because so many sick people die under the care of the greatest luminaries of medical science we should condemn this science? Nor does it seem to me right to call charlatans those who have the virtue of healing without medicine or operations, when I see them act with all simplicity and almost always free of charge. And after this long digression we return to ourselves. Healings can take place not only when the dowser is near the sick person, but also when he is at a great distance. The most eminent authors of treatises and publications on our science report many controlled and proved cases, with indication of names, places, dates, etc. Thus Father Bourdoux relates that one day, being in a town in the North of France, he met a gentleman there, who asked him if he could, in conscience, continue his charitable work without breaking any ecclesiastical law. Bourdoux found nothing reprehensible in his charitable work, and he urged him to continue, because his work was for the benefit of his fellow men. After all, what did Jesus say to his disciples? I have already mentioned it in the first pages of this paper: "When you go into a city, heal the sick whom you find there and say to them, 'The kingdom of God is at hand. (Luke X, 8, 9). Then the gentleman showed him that he was passing with his fingers over several photographs that he had on his desk without touching them. They were photographs of sick people far away who came to him to be healed, because he had proved that it was possible in many serious cases. And these sick people were to be found all over France, in Belgium, Switzerland, Morocco and even in America. After some time, Father Bourdoux returned to visit this gentleman and asked him if he could communicate to him the recent results of his cures. Here I yield the word to Bourdoux. "He (that gentleman) stretched out his hand on a table and said to me: Look at this photograph of a

vertebral column and read what the radiologist has written there . And I read: two broken vertebrae and two or three wedged into each other. Notice the date," insisted Mr X... "Now read this letter which I received. In this letter, the sick man himself expressed his gratitude by saying that he was no longer in a cast, while the doctors had assured him that he would have to remain in one for at least six months. He had now avoided this most painful treatment, and was already getting out of bed and beginning to walk without crutches. And I read various other letters of this kind, which I picked up at random from the table. Do you heal all the sick? I asked him. No, no," he answered, "and I do not understand why some are cured and others are not. There is no rule about this. There are those who are very seriously ill and who heal "very well, as you have seen, while there are those who have almost nothing and who, nevertheless, do not get any better.

This is not enough. Father Bourdoux himself recounts that on Palm Sunday 1938, when he had in his home the distinguished Doctor Marty, who lived in Toulouse, on Raymond Delieu Street, he received a letter from a young father of a family in which he begged him to save his 18-month-old daughter who, by the judgment of the doctors in charge, was declared lost. "I have no hope but in you," wrote the unfortunate parent. Do not abandon me!" But he had put a lock of the child's hair in the letter. And here I leave Bourdoux to speak again. "I was about to refuse to take charge of this case because ecclesiastical and civil laws forbid me to practice medicine. It is true to him that in extreme cases the positive law makes no precise obligation. But while I was looking for a solution to this case of conscience, I said to myself: Good gracious! The solution is very simple, because I have a doctor in my house, actually a dowsing doctor! And in fact Dr. Marty immediately put himself at my disposal. So we made the examination on the lock of hair and we found that we had the necessary remedy at home; but the post office was closed because it was Sunday, while the case was very urgent. I then resorted to remote treatment. I placed the child's hair on a sheet of white paper, and for about ten minutes I laid both my hands on it. I repeated this operation a few times, with some intervals of time between each one. After lunch I did some similar impositions and around 3 p.m. I telephoned the father of the sick girl to ask for news, recommending him to

send that same evening to take the remedy to Toulouse, to Doctor Marty. I had the joy of knowing that around half past eleven, the sick girl was feeling much better, that she had sat down in her bed and asked for her toys, after which she had taken the milk she had not wanted for several days. Then she fell asleep. Three days later she was well again!

It will be said to me that these are mere cases, pure combinations. Come, then, I admit neither cases nor combinations that are in antithesis with my religious belief, for we have an ancient proverb that answers to them: "Not a leaf moves that God does not want". I put cases and combinations in the same basket in which I throw autosuggestions, because they are all vain words that do not explain anything; because, among other things, they rest neither on positive facts, nor on proven theories, or rather on solid scientific bases. Those who, for the sake of explanation, resort to terms such as: cases, combinations and autosuggestions have the effect on me of soldiers who run away at the first cannon shots finding no better way to save their own skin. For me, on the contrary, the above-mentioned examples, and many others that I could relate, prove to me the existence of three phenomena, as Bourdoux well concluded.

1°- The extension of these mysterious and beneficent waves to unlimited distances;

2° - The possibility of directing, of channelling at will both the personal waves and those of a medicine towards a given point by an act of our will;

3° - The possibility of modifying these waves, in cases such as those mentioned above to make them beneficial.

Later on I will speak at length about Dowsing applied to medicine and we will see that with these applications we reach the borders of spiritualism, without, however, entering positively into it, although we can speak of mediumship. But the real problem to be solved is the one concerning the phenomenon of mediumship. Does this phenomenon belong to spiritualism or to dowsing? It is now almost universally accepted and proven that mediumistic cures are due to the emission of special waves whose nature we still do not know. As we are dealing with waves, we are in the physical field, which has nothing to do with the spiritist field, which would like to serve as a link between the world of the living and that of the dead. But, having arrived at this point, another serious question presents itself to our minds: are the waves of which I have spoken only emitted by our bodily envelope, the hidden structure of which we perhaps do not yet know, or may they spring from other sources in our organism, for example, from our brain?

Chapter XVI

Is there such a thing as brain radiation?

Before answering such a question, I think it would be advisable to ask another: are thoughts and ideas brain radiations, or are they only external emanations that our brain receives and fixes in its mass, just as a photographic plate fixes on the gelatine the image that reaches it through the lens? When our soul detaches itself from our body in order to take its supreme flight towards the ethereal regions, no human instrument, whatever may be thought by some good spiritualists, can ever transmit to us the thought of it, but the soul that is still alive in us must act in a different way, and I say alive in order to understand ourselves, for we know that the soul, being immortal, continues its life even in the beyond. Now it is the soul that creates thought: it is not the brain. And thought, therefore, is so intimately connected with matter that it modifies our personality and exerts a profound influence upon it while, at the same time, it is profoundly affected by the influence itself. Our face, our manners, our manner of speaking and writing, our gestures, and all our external manifestations are transformed to adhere to the feelings generated by our way of thinking. It is thought that guides our every action and gives the impulse to our every act or movement, provided that the organ that transmits thought, namely the brain, is healthy and capable of receiving it. The thought, which springs from the soul, prints itself, as it were, in our brain, where it remains imprinted as long as disease or old age do not weaken this receiving organ. But the imprinting of thought in the brain, being a physical, almost mechanical act, causes, in the cerebral matter, a shock from which arise vibrations as small as you want but that our nervous system receives and retransmits enormously enlarged. Now it is a question of knowing whether it is possible to pick up by means of an instrument the vibrations produced by the meeting of thought with the brain; to put it better: is it possible to record, to grasp, with some mechanical apparatus, human thought? I do not believe that it is possible to exclude it, because we already know that with the pendulum we can obtain many answers to questions we ask ourselves mentally as, equally, we know that while we are operating with our tiny dowsing trinket, another person present there can, with his will, completely disturb its operation. In

confirmation of this last affirmation of mine I will quote another fact which is narrated to us by Bourdoux, translating his words:

"I was in Spain, and a doctor wished to witness some dowsing experiences. I gave him one: that of finding his age. And the test was very successful. The Mother Superior of a convent wanted me to guess his age as well. I didn't get it, because at the age of 45 the pendulum was swinging in a positive direction, yes, but so timidly that I didn't trust it. On the age of 54 I had the same result and therefore I could not establish the age of the Rev. Mother and I confessed it to her. Then she, who later became an eminent dowser, said to me: "While you were trying to know my age, I kept on saying and thinking that I was now 45 and now 54, because I wanted to see if I could impose my will on you! And she succeeded perfectly. From this fact I deduced two conclusions," continues Father Bourdoux: that it is possible to capture a person's present thought and that we can, likewise, impose "our thought on others.

But the apprehension of the thoughts of others falls within the field of telepathy, which, though it may have some connection with the subject of which I write, would carry me very far away, and would end by giving to this study too large proportions. However, the numerous experiments I have made personally, and which have come to my knowledge, teach me that certain experiments should not be made in public, but in a small circle of friends, or of trustworthy and sincere persons, in order to avoid that someone may prevent, hinder, or simply disturb them. Of course, if I admit that in this way one can know the dominant thought of a person at the moment of operating, I exclude that one can know a future one, because future thoughts do not exist. I also add, that not all dowsers are able to do this because a special sensitivity and a long, very long training are needed. In conclusion, and to answer to the question that forms the title of the present chapter, I believe, with almost all the masters of the modern Dowsing, that indeed there are brain waves that can be picked up in certain conditions and circumstances, whether it is a matter of individual thoughts or of collective ideas.

Chapter XVII

About the canvas - dowsing

Who knows how many readers will smile when they read this new technical word that our centuries-old and venerable Accademia della Crusca has not yet passed the test of its philological wisdom and has therefore not yet registered in its interminable dictionary of the Italian language. But if this word does not yet appear in the vocabulary of our idiom, this does not mean that soon it will be admitted because I do not know how to indicate an equivalent term. What is Tele-radiesthesia? It is the science of being able to carry out research, by means of a pendulum, on a person or on a piece of land which may be very distant from the operator, provided that he has at hand either a photograph of the person or a map of the land to be studied. Once upon a time these possibilities would have been considered absurd, madness. Today not anymore, at least for the devotees of Radiesthesia, and in this paper I will quote several examples that, I hope, will be so persuasive to chase away the doubt from those who want to embrace this new branch of the human knowledge, not for simple curiosity, which is not admissible when we are facing very high problems of art, science, or religion, but to take possession of a means, of a technique that can bring so many benefits to Humanity. For it is to this sole end that all the efforts of men of good will must tend. I too (as happened to almost all my teachers) remained, at first, very astonished and almost incredulous when the wonders of Radiesthesia were revealed to me and when new and unthought of horizons were opened before my eyes. But then I had to surrender to the evidence and, with the help of my elders (I call in this way those men distinguished for doctrine, wit and virtue, such as Abbot Mermet, P. Bourdoux, Rev. P. Gairol de Serezin, Viscount Henry de France, Lacroix-à-l'Henri, Doctors Leprince, Regnault, Marty, and many others from whom I have learned everything) I believe I have understood the origin and the causes of these amazing phenomena. How, indeed, can the tele-radiesthetic process be explained? The photograph of a person or the plant of a ground have only one purpose: that is to establish a contact between the operator and the person or the ground to be examined, because once this contact is realized, the dowser works as if he were in the presence of the person or the ground itself. We know (I have already said it) that the emanations radiated

by animals, as by any body, spread through the ether reaching immeasurable distances. These waves, emitted by an individual, are picked up by sympathy, by attraction, by another individual who is perhaps at a great distance from the first. They harmonize with each other, forming, almost, a true circuit, a manifestation of telepathy.

With all this I certainly do not want to say that even with Tele-radiesthesia no mistakes are made. And in what branch of science, please, do they not make them? They occur every day in the medical field, in the chemical field, and even in the more precise and positive ones represented by mathematics and construction. But, of course, since we are dealing here with a new science whose extraordinary possibilities astonish the profane and impress the scholars, there is nothing more natural than that an absolute infallibility should be demanded of it in order to believe in it. Therefore I will quote here some examples taken from the often cited book of Ettore Mellin:

1. Mr P..., a resident of Angers (France), lost his dog two months ago. Not knowing how to find it, Mr P. sent the dog's collar to Mr E. Mellin, who lives near Paris. Mr Mellin, who lives near Paris, sent the dog's collar to Mr E. Mellin who, without moving from his home, in a few minutes managed to identify the precise location, the farmhouse where the dog was being kept, and informed Mr P... who in fact found the dog in the designated place.

2° - Staying always at his home he is entrusted by the Mining Company of Clairefontaine and El Mila to study the mountain of M' Kririga which is in Algeria. The result of these studies made at such a great distance is highlighted by the following letter that the Director of the Mining Company sent to Mellin on March 16, 1933.

"In order to complete his work of remote research on the plateau of M' Kririga (Algeria) of which he had already delivered to us such a brilliant study fully in accordance with the work of our engineers, Mr. Mellin sent us precise indications of a point very rich in ore and in which the same ore should be found, in outcrop, at a depth of 3 m. Orders were given, at the beginning of February, with instructions to telegraph if the mineral was found in the indicated place. Some time later, on March 2, a telegram confirmed in full the indications given to us by Mr. Mellin. I send, therefore, to Mr. Mellin my warmest congratulations for the wonderful precision with which he was able to follow and guide our research work in Algeria while he was in France. Thanks to his tele-radiesthetic method, we have found the mineral with a minimal expense".

3° - The Managing Director of the Guiana Gold Mines had asked Mr. Mellin for information about the mines themselves. After a few months, here is what the aforesaid Administrator wrote to Mellin: "We had asked you to make a tele-survey on a map of French Guiana in order to search, in a radius that we had traced, for gold deposits that could be found in that radius. The memoir you have transmitted to us confirms in every point the work done by the Company's engineers. We are truly amazed at the results of your remote investigations."

4° - Mr. Fredon, of the Minerals and Metals Company (Rue de Pétrograd, Paris) instructed Mr. Mellin to look for gold south of Figéac, although he knew that there was no trace of it there. But a few weeks later he wrote to Mellin the following:

"To my personal satisfaction I acknowledge that I delivered to M. Mellin a sample of ore for the purpose of studying the southern part of Figéac. A few days later Mr. Mellin sent me back his study indicating gold deposits to the north of Figéac, and especially at La Capelle, Terrau, Mercoeur and la Tronquières. I am forced to acknowledge, along with our engineer, that the

indications of Mr. Mellin correspond precisely to the mineralized points that we know. I confess that I am deeply amazed by the precision of his work, carried out without sufficient elements and without knowing the country signed: Fredon".

The engineer V... of Saint-Amand-les-Eaux gives Mellin a photograph of his wife, inviting him to tell him what he finds out. Mellin, from Paris, informs Mr. V... that Mrs. V... has phlebitis in her left leg. And it was perfectly true!

6° - In the periodical: La prospection à distance of February 1936 (Rue Neuve à Lecelles-Nord) we find this fact recorded:

"Miss Elina Lembeye, of Maison-Alford, established, from her home and using a 10,000 map, the precise point where Governor General Renard's plane had crashed: that is, between Lake Leopold II and the Congo River. She also said that the four people on board the plane were dead, crushed. Four days later, the official telegraphed news proved her right. The Tele-radiesthesia operations performed by Mrs. Lembeye had been supervised by Dr. Armando Viré, doctor of physical and mathematical sciences".

7. This other fact I also take from the book of Father Bourdoux. One day, one of his missionaries from Mato-Grosso, Monsignor Rey, asked him to tell him what illness one of his friends, a religious of the same order, was suffering from in a parish more than 100 kilometres away. Not having photographs or any other document of the sick man, Father Bourdoux had to be content with his name, surname and address and made use of his collection of testimonial medicines, of which I shall speak later. He examined several of these testimonial-medicines, with the pendulum, without finding anything; and the father was already discouraged, when the

pendulum began to turn positively, first on the medicine corresponding to the pulmonary consumption, then on that of the general consumption and finally on the testimonial of the visceral tuberculosis. And Father Bourdoux ended by saying to his friend, Bishop Rey: "It is useless to look for anything else. The sick man is lost. After a few days, Mgr Rey said to him: "It was precisely what you diagnosed in a few minutes, while it took the doctors six months to diagnose it.

But the Teleradiesthesia is not limited to here: it is of great help for the remote search of hidden treasures, of buried or submerged corpses also in the waters and therefore it can be of great help in the judicial and public security operations. In this regard, I translate here literally an episode written by the illustrious Abbot Mermet, one of the most phenomenal dowsers who have ever existed, which can be found in the December 1935 issue of the beautiful French magazine "Je sais tout". Here, then, is what Abbot Mermet tells us:

"In October 1933, in Montbovar (Fribourg - Switzerland), a "young man of 18 years old had suddenly disappeared on his way back home from a village festival, without any of the numerous search parties sent to find him being able to detect the slightest trace of him. Having lost all hope, his sister came to see me, bringing me a photograph of the missing person and a topographical map of the region. Sitting down, I gave this girl the following information: First of all, the photograph gives me the figure of death. Your brother has ceased to live. He travelled along such a road, and stopped at such a point. At this point, I feel your brother, height 1.55 m carried, already a corpse, on the shoulders of another man whose height appears to be 1.70 m. Your brother received stab wounds in the back at heart level. He was then thrown into the Hongrin stream at this site, at a point where the walls of the stream are very close together and where there is up to 4 m of water. It is probable that theft was the motive for the crime because I see neither gold nor silver on him. Such were the indications that I was able to give from the radiations left on the map of the region that the disappeared man had travelled. Now, here is the result: the family of the deceased

believed they were fulfilling a duty by sending me the following certificate: I, the undersigned, make the following statements: in the Parish of Jussy, by means of a simple reading over a topographical map (scale 1:25 000) of the valley of the Hongrin, without my revealing anything to him, Abbot Mermet told me: a) the route followed by my poor brother on his return from "Montbovar; "b) the place where he stopped. Both these data have been checked and found to be accurate. It is Mr. Abbot Mermet who, for the first one, had the idea of the murder, telling me that he saw him carried on his shoulders by a man about 1.70 m. tall while my brother was only 1.55 m.: something, this too found to be absolutely true. He pointed out to me with the utmost exactness the spot where my brother was, where no one had had any idea of going to look for him, namely, in the Hongrin stream, in a whirlpool more than 4 m. deep. Mr. Pfug, the clerk of the court, acknowledged that Rev. Mermet had spoken the truth when he said that there was no gold or silver on the body. A few days later, in fact, the victim's purse, completely empty, was fished out of the waters of the Sarine River much farther away. The forensic autopsy, performed the day after the body was found, showed that my young brother had been stabbed in the back with a knife and then fallen into the stream.

But in spite of all these facts and countless others that I could mention, we must not believe that the method is infallible. Rev. Mermet himself, who, I repeat, was undoubtedly one of the greatest world exponents of this portentous science, also admitted that many mistakes can be made, as it happens in every other field of knowledge and human activity. Also another valorous dowsing as the Count de La Bastide, recognizes that the best operators can record up to 20% of errors made in their researches. Is it a lot? It doesn't seem to me, and it doesn't seem to me, either, that such a weak percentage of failures can condemn Tele-radiesthesia, which can render immense services to Humanity, since our aim, our efforts must all tend to this end: the good of Humanity.

Chapter XVIII

Colors

Do colors possess any special characteristics? Do they have any power over our organism? Do they exercise any benign or malignant influence upon our existence? Almost all, not to say all, the lovers of this science of ours agree in affirming it, starting from this principle: that at the moment of our birth some predominant stars shine in the sky, the radiations of which intervene in the chemical composition of our body, dominating it for the whole duration of our earthly life. From this theory, which must be as old as the world, were born, certainly, those sayings that we all know and that we take so lightly: "born under an evil star" or "born under a benign star". These phrases may, by many, be considered as simple metaphors, like any popular motto. Yet how much truth is contained in them! Let us briefly examine the problem from the scientific point of view. I have said that at the moment we are born some star predominates in the firmament; and the first kiss we receive from Nature is given to us by that star through the cosmic rays with which it envelops everything. But these rays, which have penetrated deeply into us and will never leave us again on our earthly journey, have special vibrations and special colours and shades. The eminent Dr. Paul Chavanon has already succeeded in establishing a scale of 144 different tints; but these tints are still clearly perceptible to our eye. How many other tints, how many other shades of colors exist that we cannot grasp? Thus, when we speak of luminous rays we mean those waves, or vibrations, more or less micrometrical, which strike our senses sensibly or not. But each ray has its own colour: each colour corresponds to a series of vibrations. In fact it is known that the vibratory frequency of colours is as follows:

Violet, 770 trillion vibrations per min. sec.

Indigo (or indigo) 710 trillion vibrations per min. sec.

Turchino, 650 trillion vibrations per min. sec.

Green, 580 trillion vibrations per min. sec.

Yellow, 530 trillion vibrations per min. sec.

Orange, 500 trillion vibrations per min. sec.

Red 450 trillion vibrations per min. sec.

The dynamic power of these vibrations diminishes as we move away from the violet towards the red; vice versa their vibratory system, or rather the intensity of their vibrations, increases in the opposite direction to the diminution of their dynamic power. Now, then, it is admitted that the slightest shade of a hue acts differently from the others upon our nervous system. We know that there are seven colors in the chromatic spectrum, and they are classified in this invariable order: violet, indigo, turquoise, green, yellow, orange, and red. Each of them has its own fundamental Ray with a well defined and constant direction of orientation, namely:

1st - Purple - to the North;

2nd - Indigo - North - East;

3° - Turchino - to the North - East;

4th - Green - to the East;

5th - Yellow - East - South - East;

6th - Orange - to the South - East;

7° - Red - in the South.

Of these seven colours, three are called fundamental because they are of pure origin and each of these three colours has its own peculiar characters and influences or effects. Indeed:

the Turchino corresponds: to the silver, to the zinc, to the phosphorus, to the chlorine and to the bronze, to the blond people; and it emits radiations: microbicidal, antispasmodic, anaesthetic, analgesic and vitalogenic;

Yellow corresponds to: argon, nitrogen, sodium, calcium, copper, molybdenum, fluorine, etc.; it increases the general neuromuscular tonicity in individuals;

the Red corresponds: to the iron, to the gold, to the cinnabar, to the wolfram, to the manganese, to the potassium, to the strontium, to the hematite, to the arsenic, to the oxygen and to the brown people; it emits radiations: energetic, congesting, antiseptic and healing.

Three other colors are called complementary because they result from the mixture of other colors, and are:

Violet, which corresponds to nickel and tin; its radiations are essentially psychic and calm insomnia;

The Green that corresponds to: the silicon, the magnesia, the water; to the red-haired people; its irradiations are perturbing; they generate some pathological troubles and favor the bestial and material instincts;

Orange, which is the colour of dark brown people and of shy, irresolute and chaste people;

Indigo, the bearer of psychic and vital vibrations that strengthen the spirit.

All these colours are the ones we meet in the right sector of the Wind Rose going from North to South and passing through the East. If, however, we go from the South to the North passing through the West, we encounter dark radiations, such as:

in the South, against the Red, infrared;

to the South-West, the Black and the infra-black rays; between the black and the grey we find the rays corresponding to death;

in the West, the gray;

to the Northwest, the White and the ultra-white rays;

to the North - North - West, the ultra-violet; and, close to these, the unknown rays; then the X-rays; then the ultra-violet and finally: the Purple.

As we see, the scales or distributions of colours, here reproduced, are those established by Newton, although modern physics somewhat varies their disposition in regard to Indigo. But these differences are of no interest to us, who care rather to know the influence of them upon our lives. First of all we must know that the luminous propagation of colours is not always identical at every hour of the day or night; that is to say, that the intensity of this diffusion is not always the same. The maximum intensity of these radiations are (as I find listed in Mellin):

for the Viola all night and especially around midnight;

for the Indigo a little before dawn;

for the Turchino from 7 to 9;

for the Green from 9 to 11;

for Yellow from 11:00 a.m. to 2:00 p.m;

for Orange from 2 p.m. to the beginning of sunset;

for the Sunset Red.

But the manifestations and characteristics of the colours are not limited to those I have so far enumerated; there are others that must be considered and known by us. Thus:

The Purple, the Indigo and the Turchino emit a negative radiant energy, cold and calming;

Yellow, Orange and Red emit, instead, a positive, warm and exciting radiant energy;

Green, resulting from a mixture of Turkish (negative) and Yellow (positive) is a colour that can be neutral.

Finally, in their relations to the disposition of individuals, colors have these correspondences:

to Black corresponds pessimism, melancholy, doubt;

to Grey corresponds: resignation, uncertainty, doubt;

to White corresponds: optimism, joy, candor, sweetness;

to the Malva corresponds: spiritualism;

to the Purple One corresponds: sadness;

to Indigo corresponds: devotion;

to the Celestial corresponds: senility;

to the Turchino correspond: the joy and the nobility;

Green-blue corresponds to altruism;

The green-gray corresponds to treason;

to the Green - alive corresponds: a superficial nature;

to Yellow corresponds neglect, indolence;

Orange corresponds to: tranquillity, ponderation, balance;

To the bright Red corresponds: an irritable and authoritarian disposition; to the light Red corresponds: energy and vigour;

Dark Red corresponds to: sensuality, inertia and lymphaticism;

to the Purple Red corresponds: solemnity;

To the Pink corresponds: humility, shyness, and neurasthenia; to the Dark Brown corresponds: satisfaction; to the Light Brown corresponds gravity.

As we can see, colors have a direct influence on the character of people, which influence is revealed to us by dowsing procedures. It acts actively not only upon human creatures, but also upon animals. For we all know that the bull and the turkey are excited by the sight of red, while flies, which are attracted by soft colors such as pink, light yellow, pale green, shun black and turquoise. Butterflies prefer to settle on flowers that have their own colours, just as bees love blue and yellow flowers and avoid dark colours. Therefore, it is a great mistake to neglect the choice of colours in dressing, furnishing rooms, etc., because they emit real energy which is transmitted to our epidermis and affects our eyes and our other senses. The coloured radiations are transformed, in our organism, both in vitality and in weakness, raising or lowering our physical and psychic qualities. Now, since everything that surrounds us is colour, it is evident that our whole being comes to be completely pervaded and subjected to it. Therefore, if we live in an environment in which the most appropriate colour for our person predominates, we find ourselves in more advantageous conditions for our physical and spiritual well-being. In what does the environment of colour consist? In the clothes, in the tapestries of the rooms, in the flowers that adorn the house, in the jewels, etc., etc..

Clothes. - Many people, especially of the fairer sex, wear clothes of any color with the greatest indifference, without wondering, without caring in the least whether that color does not emit radiations that may be in disagreement with their organism. But the colour of a dress is in itself an ornament which must make a person's appearance more pleasing. Particularly for ladies, the colours of the clothes must harmonize with the colour of the skin and hair, so that they can make the most of their venustious qualities. For example, a brightly coloured dress will suit a young person better than an old one, while a plain dress, which is always monotonous, will suit an older person better. So if the fabrics are of two or more bright colours, they will not be beautiful if the aforementioned colours are opposite to each other. Now, in order to establish in the simplest way which colour suits a person best, there is nothing better than to resort to the usual pendulum. How? Take, one by one, some pieces of coloured paper or cloth and hold them in your free hand at a distance of about 30 cm from the

person you want to dress, and with the other hand hold the pendulum between the coloured sample and the person for whom you are working. If the color does not suit the person, the pendulum will swing or turn in a negative direction. If you have found the harmonizing color, the pendulum will swing in a positive direction.

Home furnishings. - By furnishing I mean mainly the upholstery, the wall paintings, the pictures, etc. and everything that serves to furnish the living room, the dining room, the study and, especially, the bedroom where man, in the repose of his daily toil, remains motionless for several consecutive hours, absorbing the rays emanating from the colors that surround him. Each individual has a colour that is attuned to his own organism. This colour, by contrast of polarity, demands imperiously another of opposite sign; but such contrasts must not exist only between the individual and the environment that hosts him; it is necessary that they exist also in the same furnishing. For example, a room wallpapered in red with gold trim, despite the appearance of luxury that may result, will be disharmonious because both red and gold carry the same positive sign. The dominant color of the woman is generally the opposite of that of the man and vice versa, and therefore the woman will have to look for her contrasting color in the scale of the fundamental color of the man, as this will choose his in that of the woman, otherwise nothing is easier than for the influence of colors, where it is a matter of two spouses, love and harmony do not reign between them. For example, suppose that in a room decorated in red, there are two spouses living together, the wife of whom has black hair. Since the wife is in herself exuberant with red radiations, she will be in complete disagreement with her room, and, what is worse, with her husband. For the aforesaid red radiations, united with those emitted by the brown woman, will excite the nervous system of the latter and make her irritable and violent. Hence we will have her discord with her husband. Vice versa let's examine the case of another married couple of which the wife is brown and the husband blond. The latter will have his dominant color in the turquoise range and his complementary in the red, pink or yellow range, while his wife will find her fundamental color in the reds and her complementary in the indigo, turquoise or purple scale. If the decoration of their room responds, in the

colors, to those solicited or desired by their organism, we can assume that the couple will get along perfectly. Therefore, also for this we resort to the pendulum.

Part Two

Chapter I

Dowsing in aid of Public Security

I dedicate this part of my writing to my illustrious and dear friends Prof. Giuseppe Falco and Dr. Ugo Sorrentino, respectively Director and Vice-Director of the Superior School of Scientific Police, who with such doctrine, such enlightened intelligence and such fervent passion dedicate all their energies to the direction and increase of an Institute of such high social importance destined to fight crime and to protect the security and immunity of citizens, property and the Nation. Radiesthesia abroad, and especially in France, has become a formidable auxiliary of the Public Security, which today makes wide use of it and is establishing, as in England and Germany, Schools and Offices of Radiesthesia. And so far many and excellent results have been achieved because those who have dedicated themselves to it, after a suitable period of study and training, have been persuaded of the wonderful possibilities that this new science offers us and of the precision of the indications that it can give us. And if, at the beginning, as it always happens, many wrinkled their noses, and laughed at Dowsing, and derided it without even knowing it by name, today most of them have converted and reconsidered. The truth always ends up making its way and imposing itself, because time is a gentleman. In fact, this very modern science, which embraces and uses so many others, can, in the field of Police, serve for the most diverse investigations and make an enormous contribution to the speed and resolution of many of those difficult problems that often disturb the sleep of our good officers and for which one would often invoke the intervention of some Sherlock Holmes. I will try, therefore, to examine some cases that may serve as a guide for the future conduct... of police operations; but first of all I remember that almost always the dowser will have to be equipped, for greater security, with some witnesses for research. The reader already knows that by witnesses are meant some objects that have belonged to the person on whom the investigation is carried out, namely: a photograph of him, a piece of writing, a piece of clothing that has belonged to him, etc...

Simulation of infirmity. - Generally the individual who is to be subjected to the relative examinations is always present, therefore the operations of the case can be carried out directly on him. The most frequent cases of simulation of infirmity are those by means of which a person wants to appear idiotic, deaf, of weak sight, or suffering from fever, etc.. These simulations would have the purpose of evading military obligations, of being declared irresponsible for crimes committed, etc., etc. But with the dowsing test almost always (in 95% of cases) the fraud is foiled. A French military doctor, Dupuis, tells that a recruit called to arms in 1917 and assigned to an infantry regiment declared to be completely deaf. In fact, in spite of all the tests performed on her, she could not be moved to contradict herself. The military medical authorities were about to reform it, when one of the young doctors, who was already interested in dowsing, wanted to try, in agreement with his superior, the pendulum test. Having made the supposed deaf person lie down on a camp bed, the young pendulum player held his device suspended over the recruit's right ear, and then over the left one. Now on the left ear it swiveled rapidly and with large turns. The Radiesthesiologist concluded that the soldier examined heard perfectly from the left ear and a little less from the right one. Then, in order to frighten the false deaf man, he said to his superior in a loud voice: "Yes, yes, Major. This wretch must have a tumor in the back of his skull. Tomorrow morning we'll have to operate urgently: we'll have to open his skull here. And so speaking, it indicated to the major doctor the position to be drilled. The major then replied to his young colleague: "Very well. You can give all the orders for this operation to be carried out tomorrow morning. Upon hearing such a speech, the recruit jumped out of bed shouting, "What operation do you want to do to me?". The deception was revealed and the pendulum had achieved what it had never managed to achieve in any other way. Easier is the recognition of the eyes. I have already cited an example in this connection, from which the indisputable efficacy of the pendulum for the exact evaluation of the greater or lesser visual faculty of persons has been demonstrated.

Let us turn to mental deficiencies. We know that the brain is one of the greatest sources of physical and psychic radiation. If we suspend the

pendulum over the head of any individual in good or normal mental condition, while we place a finger of the free hand on the body, we shall see that our little apparatus will swing in a positive, that is to say, an affirmative direction. If, on the other hand, the person undergoing a psychiatric examination makes the pendulum swing or turn in a negative direction, we must conclude that his brain condition is not normal. To be more sure of the test it is opportune to make it also on a subject that effectively presents the anomaly supposed in the suspect individual.

Blood tests. - Often the competent Offices of the Public Health have to carry out blood tests which may present doubts or difficulties. Also here the pendulum will help us with great promptness in its answers. Let us suppose that we have an object stained with blood. Is it human blood? Is it some animal's blood? To know precisely and quickly, it is enough for the operator to soak a piece of paper or cloth with a few drops of human blood (perhaps he can get it from a finger with a simple needle pricking), which will serve as witnesses and which he will touch with his free hand, while with the other he will hold the pendulum suspended above the bloody object to be analysed. If the pendulum turns positively, it can be considered for sure that it is human blood. If the pendulum, instead, will give a negative answer, we will know that we are in front of the blood of some animal: hen, rabbit, pig, horse, etc.... Well, to know what kind of quadruped or biped that blood belonged to, we will operate as we said above using as a witness the blood of hen, rabbit, pig, etc. until our device, with its positive rotation, will solve the question. This is because of the phenomenon of identity of which I have spoken.

Forgery of paintings, writings, etc.. - These searches are the easiest and abroad are already widely used, especially to recognize, or not, the authenticity of paintings, sculptures, etc.. Let us suppose to have to examine a painting attributed to Corot. The surest method is to use, as witness, a painting truly and notoriously authentic of Corot himself. The Dowser will examine with his apparatus the suspected painting, keeping his hand free on the authentic one. The pendulum with its movements will tell if it is real or if

it is a fake. If, instead of a painting, we find ourselves in front of a signature or a writing about which there are doubts, we will operate as in the previous case, taking as witness an authentic writing of the person to whom we would like to attribute the suspicious documents. If there are no authentic paintings or writings, a photograph or a print reproducing the portrait of the author can be used. And the same should be done for medals or modern or antique coins; for jewellery, etc. etc..

Police investigations. - These operations embrace a field so vast that it would take a special volume just to illustrate them. Therefore I will only mention some of them, because the method I shall indicate can be applied to an infinity of cases and can be developed by one who devotes himself with love, constancy and intellect to this study. I have already cited an example of the discovery of the corpse of a murdered man by the Rev. Abbot Mermet. But how did this illustrious dowser proceed in his operation? We know that he had two elements: a photograph of the disappeared person and a topographical map of the region in which was included the place where it was known that the victim had been seen for the last time. So Mermet, keeping one hand on the photograph and the map spread out before him, let his pendulum drop perpendicularly on the precise point where the young man had left the group of friends accompanying him. Then by slowly swinging the pendulum over the map, now in one direction, now in another, the operator was able to identify various places through which the deceased had passed. And so, by connecting these various points, and continuing his investigations, Mermet had managed to find the entire path followed by the unhappy boy up to the place where he was attacked and up to the point where he was thrown into the stream that was to serve as his grave. But one would like to know how the famous radiesthesist came to know all the other details relating to the crime, which consist of the following:

1° - Location of the murder, and that where the body was thrown into the stream;

2° - Way in which the murder itself was carried out;

3° - Because Mermet said that the corpse was carried on a man's shoulder;

4. How he establishes the stature of the victim and that of the slayer;

5° - How did the Abbot establish that the slain had neither gold nor silver on him.

In answer to the third question I will say that the operator felt with the pendulum that, at a given point, the ground lost the remains of the individual sought, while he found it in the bed of the stream. There was, therefore, an interruption in the path followed by the deceased, which meant that he had been transported there. The other questions Mermet answered either by asking them mentally, or in writing. The latter means is the most practical and common. This is how Mermet evidently worked. He will have written on a sheet of paper the following questions:

a) Young X..., was he killed?

(b) Young X was treacherously shot to death?

(c) Young X..., was he stabbed?

d) Young X..., was he hit in the front?... Was he hit in the back?

(e) when the victim was thrown into the creek, was he already dead?

f) was she carried into the creek in a vehicle?... Was she carried on her back by the murderer?

(g) was the theft the cause of the crime?

All these questions the Radiesthesist asked on many little sheets of paper while he kept one hand on the photograph of the disappeared and while with the other hand he held the pendulum that, with its movements, answered yes or no. It remains to be explained, however, how Mermet was able to indicate the stature of the two actors in that drama. This research calls for a rather exhaustive explanation because it is applicable to many cases even of practical life, excluding, of course, that which may concern the lottery because if this method were applicable to this government institution, the State would have to abolish it immediately. Here it is useful to warn once and for all that with Dowsing we will never be able to know the future, nor to guess the lottery numbers. And this is logical because the future is known only to God, while if we could know before the draw the lucky numbers that would bring us sudden wealth, we would cause the financial failure of the Treasury with the irreparable ruin of the Nation. Therefore everything that is contrary to what is lawful can never be obtained dowsingly and we can not even know in advance the results of

operations or economic and material affairs that we are about to undertake, both because this falls into that knowledge of the future that, as I said, is the exclusive domain of the Heavenly Father, and because in our earthly affairs we are always linked to third persons on whose free will we can not in any way influence.

Let us return to the case we are dealing with: research of the stature of a person. The dowser writes on a sheet of paper a given number of digits, which can be adapted to the height of the person under examination. Being a murderer, one understands that he had to have a certain number of years and, therefore, a corresponding height. Therefore Mermet will have written, well spaced between them, the following numbers: 120 - 130 - 140 - 150 - 160 - 170 - 180 - 190 - 200 which represented, in centimeters, the height of the individual, and held suspended over each of them his pendulum that will always have oscillated negatively on all the numbers written while on 170 it will have turned positively. But when the operator will have searched the height of the murdered (1.55 m) the pendulum will have rotated between 150 and 160. And then Mermet, to have the maximum precision of response, will have written on another sheet: 150 - 151 - 152 - 153 - 154 - 155 - 156 - 157 etc.. By examining them one by one, he will have seen the pendulum turn positively and energetically on 155. He would have done the same if he had wanted to know the weight; he would have written: 40 - 45 - 50 - 55 - 60 - 65 - 70 - 75 - 80 - 85 etc. and he would have, without fail, obtained the desired answer. And since I am speaking of this system of investigation, I will complete it by also indicating the way to find the name and surname of an unknown person of whom we have either a photograph, or a writing, or a piece of clothing, etc.. First of all we will have to try to know how many letters make up his name and his surname, always using a row of numbers. 2 - 3 - 4 - 5 - 6 - 7 - 8 - 9 - 10 - 11 - 12 - 13 - 14 - 15 etc... Assuming that the first name has 6 letters and the last name has 8, we must now find the corresponding letters. So we will form a picture as follows:

A-B-C-D-E-F-G-H-I-J-K-L-M-N-O-P-Q R-S-T-U-V-W-X-Y-Z and we will mentally ask (while we always keep one hand on the witness and with the

other we will make the pendulum swing on the letters): is the first letter of the name A? is it B? is it C? etc.? Once we have found the first letter, which, we suppose, is D, we will look for the second, which will be O, then the third N, then the fourth A, and the fifth T, and finally the sixth O. Thus, in the meantime, we will know that the name is Donato. Working in this way we will also find the surname. Certainly it is all a work of great patience that requires absolute tranquillity of spirit. Physical and moral pains do not allow us to operate with that serenity which is indispensable for the success of the work. Finally, to return to the fact that we have taken as an example, it remains to be known (question 58) how Mermet was able to know that the murdered man was wearing neither gold nor silver. In order to obtain an answer, it was enough for him to hold, in the hand that held the pendulum, first a gold coin, then a silver one, while he put his finger on the photograph. The pendulum evidently answered negatively and therefore he was able to communicate this information to the murdered man's sister who was present at the dowsing operations. But the police investigations with the pendulum certainly do not stop here. Let's keep in mind that with any witness of a criminal or a victim it is possible to reach the personal identification, the reconstruction of the crime, the roads travelled and the finding of both. The same fingerprints can suffice as witnesses because they emit radiation that can guide us in our research. For example, the thief or the murderer, after committing the crime, has run away. We must track him down. Certainly he will have left his radiation either in the prints of his feet or hands, or by the simple contact of his clothes, etc. The police officer will find, on the spot, the body of the murderer. The police officer finds these remnants at the scene of the crime with his pendulum and counts their oscillations or spins. When he has ascertained and checked them, he already has a starting point. He takes as a witness an object which gives off the vibrations found: a piece of paper, a carpet, etc., then he takes a topographical map of the place where the crime took place, and, working like Mermet, he follows point by point the trail of the offender until he finds him in his refuge. We come to another case. In a city subversive posters have been scattered during the night. One of these manifestos is sufficient to constitute an excellent testimonial, because, unless they have been thrown from an airplane, they will allow us, by the same method, to find the route taken by the person who distributed them. And so it is also for anonymous letters, whether they have been typed,

because the sheet of paper must, necessarily, have been touched or handled by the person who wrote it. For the identification of anonymous writers, some dowsers resort to more complicated methods, when they have no other means of research. For example, Father Bourdoux successfully uses his collection (trousse) of medicines of which we will speak later. By means of this trousse he identifies the medicament that the writer may need. From the medicine found (always using the pendulum and the incriminated letter) he comes to establish which disease the author of the letter is suffering from. So if the pendulum has started to swing positively on the medicines corresponding to the following diseases: liver failure, pulmonary tisis and asthma, he can establish that the writer is suffering from these three illnesses of which he can also specify the degree of severity. These indications already serve as a starting point for further research because the addressee of the letter can in this way review all the people he knows and see if, among them, there is one who suffers from the above-mentioned infirmities. When he thus comes to have doubts about someone, it is necessary, in order to complete the investigation, to procure any object that has belonged to him. From the pendular examination it will be evident whether the person under suspicion is the one who wrote or sent the anonymous letter in question. With this procedure Abbot Mermet, at the invitation of the Police of a French city, was able to identify the person who had addressed a threatening letter to the Director of a large industrial company. The police had not succeeded in their search. Mermet, in a short time, was able to tell the Director of the Company, after the examination of various objects that had been provided to him as witnesses, that the author of the letter was one of the office girls. And that was indeed the case. And since I am speaking here of writings and letters, especially, I will pause for a moment to point out how important the examination (from a dowsing point of view, not a graphological one) of handwritten pages is. Graphology studies handwriting word by word, or rather letter by letter; from the vowels more or less open, more or less developed, from the strokes that cut the t-rods, and so on, it believes it can identify the character of the writer. But Radiesthesia has another method, perhaps more practical and more precise, inasmuch as it always makes use of the pendulum, and, from the direction of its oscillations or of its turnings, deduces the mentality of the person who has written the writing under examination; according, therefore, to the precepts of Mrs. Loeffler Delachaux and René Lacroix, we shall have the

following responses: when the pendulum swings perpendicularly to the lines of the writing, the character of the writer is characterized by feelings of altruism and generosity, and the wider the oscillations, the greater his intellectual and spiritual gifts; when the pendulum swings in the direction of the lines, it will tell us that the writer possesses the straightness of conscience, but poor and narrow ideas; se il movimento oscillatorio si trasforma in ellisse, dedurremo che l'autore dello scritto ha idee confuse; se, poi, il pendolo gira nel senso destrorso lo scrivente è bugiardo e malvagio; se gira in senso opposto all'orologio ci troveremo di fronte ad un individuo che è incline alla menzogna, sciocca, incosciente, abituale, ma non malvagia.

Certainly the dowsing analysis of a writing should be done sentence by sentence and someone also suggests to use a different pendulum if it is a man's or a woman's writing. For the woman a small, light, indigo or violet pendulum is recommended; for the man the common pendulum. But I think that these are not indispensable conditions for the success of the experiments, because I believe that the color, the shape and the weight do not have an absolute and decisive influence on the device. The main success factor is always the operator, or, to be more precise, his dowsing sensitivity. In any case, this application can be of great help in judicial appraisals and I call the reader's attention to it.

Chapter II

Dowsing against the enemies of the nation

The Rev. Bourdoux, in this connection, writes the following golden words, which I translate literally: "Dowsing is called to render distinguished and immense services to the Nation which will know how to favour its practice and train good practitioners. I will exaggerate even more, even if this is an exaggeration; and I say that the very life of a State will depend, perhaps, one day on the way in which the pendulum and the rod will be used in them". Today these sentences may seem, to the inevitable incredulous, more than an exaggeration, a true paradox. And yet often nothing is closer to reality than paradox. Apart from the certain and precise indications that Dowsing can give us on the deposits of rich minerals hidden in the depths of our soil, and that therefore allow us to extract an immense heritage ignored and unused, it helps us to protect the country against all those who in one way or another try to damage it or in their own interest or in the interest of other people or other nations. I will not speak here of the many common cases that occur every day. Let us leave it at that. De minimis..., with what follows. Who knows what will come of it! But certainly great dangers present traitors to the Fatherland. I understand that the phrase is very broad, because whoever fails in his duty to his country, to his brothers, is a traitor to the Fatherland, because it can be damaged not only by a reprehensible action, but also by an omission of his obligations, by negligence or inaction that can also be considered guilty. I speak here of the spies which every so-called civilized nation wisely distributes in the houses of its neighbors, in order to prepare the ground and introduce the sharp weapons which tomorrow, at the first opportunity and on the slightest pretext, will serve them in the work of violence, oppression and destruction. It is therefore necessary that the authorities know and keep an eye on many individuals who circulate freely in our country. They are men and they are also women: these, perhaps, more dangerous than those. They travel by railroad and especially by car; they frequent large hotels as well as modest inns; they go to the greatest theaters and cinemas; to dance halls as well as small cafes, but everywhere they watch, listen, observe; they make friends with officials of the State, with officers of the Armed Forces, with professionals, with simple private employees and even with workers and

common people. And like the bees that settle on this or that flower and remove that microscopic grain of sugar that in their hive they will then transform into fragrant honey, so they collect information, which, coordinated and brought together, will form abroad those famous *bordereaux*, in which are enclosed the most hidden secrets for our security and our national defense. Now, since God puts in our hands this small, but also great means of protection, since He gives us, in the tiny pendulum, such a powerful weapon of defense, why not use it? It will be asked: and how? This is another matter. I can teach you, very modestly, how to use the pendulum and how much variety of investigations can be carried out with it; but certainly I cannot indicate the ways to follow to unmask a spy or a traitor. I have never been a civil servant or a Sherlock Holmes-type detective. However, I think that as you can follow the track of a criminal on a map, so you could also follow the track of a person who, with his mysterious or inexplicable comings and goings, arouses some suspicion. It is not difficult for the organs of the police to have some evidence of this: a written document or a photograph is sufficient. With these objects in hand, many sensational discoveries can be made by those who have the means and the faculty. A simple signature is enough to illuminate the pendulum and the pendulist. So why not have the incoming customer sign the hotel form? The card sent to the police station would already be an important testimony. I have already said that with the pendulum it is possible to identify forgeries of paintings or writings. It is much easier to identify forgeries of passports or other similar documents. Let's come to another application of Dowsing that goes beyond the police field to enter the military one. Precisely while I am writing these pages our newspapers are publishing a news (according to them amazing) that let us know that the English, at present at war with Germany, are in possession, it seems, of an electric apparatus with which they can identify with precision the position of the enemy's batteries. I confess that what is sensational in this news, I found only the ignorance of the journalist who published it, and who, it is evident, does not follow the new discoveries of science. For if he had done so, he would have known that the *repérage*, that is, the search for the location of military bodies or enemy artillery, has already been carried out with complete success, by means of dowsing, for many years. In fact, in order not to dwell with so many quotations, I will report here what Bourdoux narrates on page 282 and following of his book *Notions pratiques*

de Radiesthésie mentioned several times. He recounts, therefore, that a young lieutenant, an ardent devotee of the pendulum, wagered with his colonel that, being at a distance of at least 20 km from him, he would be able to tell him where the colonel himself would place the two batteries and where he himself would establish his command post. Thus agreed at about 10 o'clock the lieutenant carried out his research on the map of the general staff. It should be noted that this was the first experiment of its kind that the young officer had performed. Nevertheless, he was able to precisely find the place where one of the batteries was placed and where the colonel had been for over an hour. He was wrong, however, for the second battery. After the rehearsal, the colonel, who was also a good dowser, said: "It is very good for a debut". Lacroix-à-l'Henri, in his *Manuel de Radiesthésie*, tells us how a French admiral, a passionate pendulum player, being on board his cruiser, could perfectly follow the path followed by a submarine belonging to his team, from its port of departure to its point of arrival. On the contrary, the admiral was able to ascertain that the submarine had not followed the course it was supposed to have followed; and when the commander of the submarine was called to report by his superior, he was astonished and confused, and had to admit the correctness of the observation. All this shows the great importance that, also for the Army and the Navy, Radiesthesia can assume; and much harm would be done if it were neglected. In Germany, as I have already said, there are thousands of officers and non-commissioned officers who take regular courses and cultivate this science in the same way as they apply themselves to mathematics, ballistics, tactics, strategy, etc., etc. Why isn't the same done here? Certainly Tele-radiesthesia, which when applied to the purposes here mentioned can and will (I am persuaded) render immense services, has, like all things of this world, its failures and defeats. But what does this mean? Perhaps because there are sick people who die, despite all the most wise treatments, perhaps because there are surgeries that fail to save the sick, we should condemn and abolish medicine and surgery? Never again. However, in tele-radiation operations one must go methodically and calmly. I have already mentioned it, but I think it is good to repeat it, also because this will be useful when we will talk about the search for minerals, treasures or archaeological remains hidden or buried. The pendulum will have to be light: about 20 grams; its shape can be spherical or oval but always with a thin lower point that serves to indicate with greater precision a point on the

paper. Witnesses are always necessary. To perform the operation of research you will lay before you the plan of the place, the farm, the city or even the only house on which you want to make the study. These plans will always be oriented to the north. The Radiesthesiologist will hold in his hand the witness and the pendulum that he will slowly slide on the paper, while he will hold in the other hand a thin wooden point, or of ebonite, or of galalite, that he will also slowly slide on the plan. When the point coincides with the place where the body or object is located, the pendulum will begin to swing in a positive or negative direction, depending on the polarity of the body or object in question. There are also other methods, but all of them are much more complicated; and although some authors are in favor of these complications, because they assert that more precise results are obtained, I do not think I recommend them because they make operations more difficult and errors easier. In order to succeed in Tele-radiesthesia it is necessary to have a good strength of will that knows how to overcome and to dominate the autosuggestion, it is necessary to abstain completely and to possess, almost, a certain disposition, or aptitude, for mediumship or clairvoyance.

Part Three

Search for minerals, archaeological remains and treasures

Here we enter a very dangerous field or, at least, a very delicate one, because in speaking of the research of minerals I will hear against me all the geologists, all the professors, all those, in short, who believe only in their own science and in what they have learned at school or in books. I already know that the theories we expound, and which are not mine alone, will be opposed by the voluminous texts of Official Science and that our modest pendulum will be answered by the multicolored geological maps. But I, as a scholar, as one who has spent all his now not short existence to question Nature in all its manifestations and to try to scrutinize the mysteries, I bow respectfully before those sciences that represent the immeasurable sums of intellectual efforts made for centuries and centuries by thousands, by millions of men, who have tried to snatch from Nature itself a part of the arcane treasures that it hides from us. Not only that: men have, in their pride, wanted to climb the ladder even to the Divinity; they have tried to take possession of attributes that are the exclusive domain of the Creator: as, for example, perpetual motion. Now only God is the animator of the perpetual motion that we see realized, in every minute second of our lives, in the eternal motion of the whole planetary system. I bow respectfully, I repeat, before Science, but with this I do not accept with the dogma of faith all that is taught today, all that is printed, just as I do not close the doors of my brain to some new ray of light, to some new branch of human knowledge. And therefore, when people want to demolish the pendulum with geological maps and geology, I reply: What is geology? It is the beautiful history of our globe. But how did you compile your geological maps? Is it possible that you have done all the surveys necessary to establish the actual structure of the 510,080,000 square kilometers that make up the surface of this Planet of ours? Is it possible that you have drilled, in only one point, the simple lithosphere that has a thickness of 60 kilometers? How, then, have you compiled this geological map of yours if not on simple hypotheses or on calculations that may be incorrect? And let us admit that you know how to tell me that in a locality there is, for instance, a Miocene soil, and that in it you think that there may be found

sources of oil or methane, but in this way you do not know how to tell me at all where I must drill in order to find one or the other of these fuels.

You condemn dowsing and assume as your maximum argument that the Dowzers made mistakes in the indications they gave. Bravo! Have you ever counted the percentages of water or oil wells found according to the indications given by our geologists and those indicated by the Dowzers? You blind admirers of the geological map make a great deal of noise when you can catch a disciple of the pendulum in the act, but you do not confess the failures of your technicians. And yet, if in the research of water, oil, or methane sources you find 10% of the errors committed with the rod or the pendulum, with your maps in hand you have to record more than 60% of solemn failures. Moreover, you say that the pendulum is a nonsense, a charlatanism, etc.... But then explain to me why this pendulum turns positively on the back of the right hand of a woman, and why it oscillates on that of a man. Explain to me why it oscillates negatively on the positive pole of the magnetic needle and why it turns positively on the negative pole of the needle itself. Why on some eggs it oscillates longitudinally, why on others it oscillates transversely, and for others, finally, it turns in the direction of the arrows of the clock. Can you deny the mysterious influence of unknown rays or emanations? If you deny these, on what real basis can you support your judgment? I understand and appreciate the man who says, "I do not know, it may be, etc.," because there is no reason to be ashamed of recognizing that in the universe there are still many unexplored zones, many mysteries still unknown to us; but I cannot have great esteem for those who deny a priori without reason, without knowledge of the cause, but only out of an instinctive pride. Remember the episode of Pico della Mirandola who asked a noble Lady: "What would you pay, O Lady, to know all that I know?". To which the noble Lady answered, with much greater wisdom than the questioner: "I would pay much more to know all that you do not know". And with this I conclude this other digression that has been suggested to me, or rather, I would say snatched from the contempt with which a professional geologist has tried to demolish the elevation of Radiesthesia and the virtues of the pendulum. I have already spoken, in the first part of this study, in Chapter VI of the search for waters

with the rod and the pendulum, indicating also the way to establish the depth and the flow rate. I shall not repeat myself, therefore, and shall speak rather of the search for other minerals. The methods at present adopted for the search of waters, of oil, of methane, or of other minerals, may be divided into three categories which we shall call: geological, geophysical, and dowsing, including in the latter dowsing and dowsing.

The first, or geological method, would certainly be the best, if, as I have already said, we knew thoroughly and accurately the structure of our globe, or at least of its envelope, or epidermis, I would almost say. But, alas, the knowledge we possess on the subject is too uncertain and limited for us to be able, on the basis of it, to meet with the risks and large expenses of excavations or deep drilling. That Geology, besides narrating to me the history of our Planet, divides it into many eras with all its subdivisions, is all very well; but this is not sufficient to show me the precise point where I must sink a probe to search, let us suppose, for oil or methane, nor can it tell me at what depth I shall find the aforesaid fuels when there are no superficial manifestations of them. Even if I knew, through Geology, that I was in an oil or methane area, this would not be enough to start drilling which could give me negative results, as happens 80% of the time, because it is enough to move a few metres north, south, east or west to find the right point where the hydrocarbon belt passes. With this, I repeat, I do not deny neither the importance, nor the help that Geology can bring us. Quite the contrary! On the contrary, I say that it, well interpreted and used, can greatly facilitate the dowsing and dowsing researches because it can indicate a priori a place where probably oil or methane can be found. And then with our prospections with the pendulum or the stick, we will be able to check the indications given to us. If they coincide we will be almost certain of success.

The second method, called geophysical, is especially suitable for the search of waters. But this, too, is based on the radiant power of underground bodies and requires expensive, delicate and complicated apparatuses which, at the end of the day, do not give a higher percentage of success than the rod

or the pendulum, even though they require infinitely more time. Today there are many systems for geophysical prospecting. Among the best known and most quoted are that of Schlumberger, that of Loewy and Lembach, that of Lindberg and Nathorst and that of S. E. Stiattesi, director of the Astrophysical Observatory of Castello (Florence). But, I repeat, this method is especially indicated for the search for water and even it not infrequently commits errors, because there is no system that is truly infallible.

Finally, the third method is the dowsing method, which, I repeat, includes dowsing and dowsing. This too does not give us 100% absolute certainty of success. No; but at least it is quicker, cheaper and more practical also because it allows us to find on a topographical map, while staying at home, the bodies we are looking for, except to perform, then, the due checks on the ground. Besides with dowsing we can find not only water, but any body hidden in the ground and we can establish the precise and most convenient point for excavations or drillings. I do not say that mistakes are not made with this method; but they are always fewer than with the other summentovated systems. The ideal would be to apply all three at the same time and with due discernment; but here we are faced with the intransigence, skepticism and egoism, I would almost say, of the various operators, because the pure geologist admits only what his own science teaches him; the geophysicist believes only in his own, and dowsers and dowsers despise with equal solemnity geology and geophysics. Come to an agreement, gentlemen, and work together for the good of our country!

Petroleum. - It is no longer a mystery to anyone that in Italy there are, at greater or lesser depths, considerable oil sources. In addition to the well-known and productive wells in the Po Valley and the Tuscan-Emilian Apennines, we know that a considerable quantity of oil could be found in Abruzzo. A great scourge of the mining industry is represented by the so-called researchers (diviners, radiomancers and adventurers) who, having learned that in a given place there may be a source of methane, a deposit of lignite, or any other mineral, go in search of the industrialist or financier who is willing to pay them millions of liras to have the approximate

information of the place and the nature of the material. For these people it is of no importance that the mineral really exists in such quantity, at least, as to compensate for the expenses that the owner of the mine may encounter, and much less do they care about bringing some benefit to the country. No. It is enough for her to pocket a nice sum for revelations that may be fallacious, and then ... good night, sounders: what has been seen has been seen. The whole reasoning of these despicable messengers consists in this: "I, with my indications, give wealth to such and such". But they do not think that such and such a one risks a fortune in such researches, which may even be completely negative. I would understand that he who is able, in an almost certain way, to indicate to an industrialist, or to a capitalist, a deposit of copper or gold, or of lithanthrax, or even simply a source of methane, can expect a fair compensation when the mine will give the results expected by him; but that he expects in advance the payment of astronomical sums, this I absolutely do not admit because it is contrary to every feeling of justice, morality and even patriotism. And if it is just and humane that he should derive from his work, from his study and from his genius those material benefits that he is entitled to by sacred right, no one can demand the smallest sum at the risk and peril of third parties, just as no one should deprive his country of what can morally and materially benefit it; no one should, out of personal selfishness, obstruct the path of the Fatherland towards the goal of wealth, glory and power. It is not by words, or speeches, or bravado, that the national edifice will be erected, more lasting than bronze (*aere perennius*); but it is only our sacrifices, our privations, and our devotion that will form its stones, marbles, and columns. I hope that the reader will forgive me this other long parenthesis that only aims at inviting to the research of the minerals that certainly rest quietly for millennia in our subsoil, waiting for the necessity and the love for our land to push us to their research and exploitation. Returning, therefore, to the oil, I will say that this can be found either on the places or also by Tele-radiesthesia. There are many regions in Italy in which we find oil manifestations, even secular ones; and such localities are identified also in our Geological Atlas. But a superficial manifestation of oil is not enough to justify the expense of a borehole. Geology will, in fact, be able to indicate the more or less extensive zone in which such indications manifest themselves, but it will never know how to teach us the precise point to be drilled. Now it is enough to move a few metres north or south, east or west, for the well to give a

positive or negative result. With the pendulum, well used, we have at least 80 chances out of 100 to guess the exact point where to sink the probe.

How should you operate in the countryside?

According to a very good friend of mine, very good dowser, although he has several degrees (agrarian, geology and veterinary), a good method consists in this: as a pendulum he uses a little perfume vial that he has filled with oil and that he holds with his right hand, while he stretches forward his left arm, the hand of which he has also wet with oil. The hand thus extended serves as an antenna. He stands upright in the middle of the open country and turns slowly on himself. If after having completed 360° of the entire circumference the pendulum gives no sign, this means that for a great extent there is no trace of oil. If, on the contrary, in a certain direction, the pendulum begins to turn, he understands that he has identified the alignment on which there must be an oil current. Let A (fig. 43) be the point at which the operator places himself and the direction resulting from the pendular orientation be A B. After having planted in these two points, at the greatest possible distance between them, two surveyor's poles or two well visible pins, the dowser moves to some hundreds of meters from the alignment A B, let's say in C, and repeats the operation already done in A with the oil pendulum in one hand and with the other hand stretched out as an antenna. Now it is evident that at a certain point of his rotation on himself, he will meet the source or the oil-band; for example in D.

figura 43

This point will indicate a point of passage of the current of liquid fuel; but it will not tell us yet if it is the most propitious to drill because we could find ourselves either above a secondary current or at the margins of the main one. Therefore, after having planted another rod in C and another in D, we will go to this last point, and from there moving first towards A, then towards B and then towards C, still holding the pendulum in our hands but closer to the ground, we will walk slowly while carefully observing the movements of our small apparatus. When it acquires a fast and ample rotation we will stop at once and we will plant in the ground, at that precise point, a wooden stake (E) because at that point we must consider that it is convenient to carry out the borehole. However these first indications are certainly not enough to satisfy the honest and conscientious researcher who must and wants to have the maximum security in his work. And therefore keeping in mind the Fundamental Ray of which I have already spoken, and that for the oil is oriented to 45° NW, making center in E, we will describe around it a rather wide circumference until we will see the pendulum, that we hold in hand, to start moving forming or turns or oscillations. We will also fix this other point on the ground and we will verify if the alignment E F corresponds effectively to the aforesaid orientation of 45° NO. If this is

the case, we have another confirmation that we are in the presence of an oil vein, the ownership of which will be given to us with the usual system of the series (see page 87) by counting out loud and regularly, 1, 2, 3, 4, 5..., etc., for as long as the movements of the apparatus last. It goes without saying that before starting the count we must have mentally established the value to be attributed to each number: whether a metre, a decametre or a hectometre. The method described above seems to me the most practical and positive and can also be applied to the search for methane that today everyone wants, everyone is looking for, and of which everyone is talking while twenty years ago, when I first had the idea of using it as fuel for internal combustion engines, and which in fact I used splendidly for this purpose, no one wanted to know about it and no one listened to me despite all the practical demonstrations that I did at my own expense!

figura 44

But for the search for methane, which belongs to the same group as oil, we can avail ourselves of another means. Tie the wire of the pendulum to the end of a sheet of steel about thirty centimetres long, which is held in the hand at the other end; and work with it as has been said for oil. If, instead of liquid hydrocarbon, we find gaseous hydrocarbon, we shall see the steel plate rise (fig. 44), while it will tend to bend if in the presence of crude oil, and to lower still more if it is mazout or dense oils. Once a source of methane has been identified, its approximate depth will be sought using the above method. It will be asked how to keep a witness of the gas in question.

The thing is not really impossible because it can be carried in a small rubber balloon, or a woollen rag impregnated with it might be sufficient. Oil makes the pendulum turn in the direction of the clock's arrows, while methane will make it turn in the opposite direction. The serial number of oil is, according to some, 22 or according to others 24.

Minerals. - Before speaking about the research of minerals by means of dowsing methods, I think it is opportune to advise at least a summary study of rocks and minerals, because without some knowledge of such bodies it is useless to try to find them. And here I recognize the usefulness of Geology and especially of Mineralogy, because these sciences are not at all in antagonism with dowsing; but they must walk in agreement and help each other. I distinguish between geologists and geology: this is the great science of the mystery that envelops the history of the Planet on which we live; those, however, are often men, whose minds are fossilized in their doctrine, as certain antediluvian animals are fossilized in their earthy shell. I will therefore here briefly summarise a few elements of petrography, advising the reader who is ignorant of these sciences to consult some good Treatise of easy reading and comprehension. The rocks are divided into:

- Sedimentary rocks, i.e., those formed from deposits made by water (sediment), and include:

(a) Limestone (lithographic limestone, oolitic limestone, marble, calcite and Icelandic spatum, chalk, dolomite and travertine);

(b) Siliceous rocks (quartz, silica, sandstone, stoneware, pudding, kieselguhr or tripoli, quartzite, etc.);

(c) Clay rocks (kaolin, marl, slate, schist, ampelite, etc.);

(d) Carboniferous rocks (peat, lignites, lithanthrax, hard coal);

(e) Saline rocks (phosphates, rock salt, etc.).

- Eruptive or volcanic rocks, which include:

(a) Granitic rocks (feldspars, black mica and white mica, quartz) and syenite, diabase, granulite, etc;

(b) Porphyroid rocks (porphyry, trachyte, basalt);

(c) Glassy rocks (obsidian, pumice).

- Metamorphic rocks such as micaschists, gneiss, etc.

All rocks can be used in their natural state, except for those from which we want to obtain other materials such as, for example: lime, which is obtained by firing certain limestones; Portland cement, produced by calcification and

grinding of natural marl, etc.. Vice versa, in order to have usable metals we have to obtain them industrially from minerals existing in the subsoil. In other words, the metals are not already found pure in their deposits, but mixed with other bodies or under different forms or in different combinations. Thus, they are obtained:

a) Iron comes from oxides which are called, according to their composition: magnetite, oligist, hematite, limonite, etc.; from a carbonate (siderose); from sulphides (yellow and white pyrites).

Iron may sometimes, but rarely, be found in the free state under the name of native iron: but it is more easily found thus in meteorites (meteoric iron) alloyed with nickel or other metals.

b) Copper, from carbonate (malachite); from sulphides (pyrites and others) and also in the native state, crystallized in the monometric system or in masses, mixed with quartz gangue.

In these cases, the copper content in these minerals can reach up to 90%.

(c) Lead, almost always mixed with sulphur, with which it forms galena.

(d) Zinc, which is extracted from its carbonates (Calamine) and sulphides (Blenda).

(e) Tin, from its oxide (Cassiterite).

(f) Mercury, from its sulphide (Cinnabar).

g) Silver, from sulphides (Argirite). It is also found in its native state.

(h) Gold is found in its native state mixed with silver or disseminated in pyrites, chalcopyrites, quartz rocks, sands, etc., and is also found in the natural state of the earth.

(i) Aluminium from silicates (bauxite, leucite, cryolite, etc.).

(l) Barium from sulphate (Bautine).

(m) Antimony from sulphide (Stibine).

(n) Manganese from oxide (Pyrolusite).

(o) Arsenic from different sulphides (Mispikel or Arsenic Pyrite, Orpiment, Realgar, etc.).

Having said this, as we can see, in brief and very schematic way, it is evident that if a Radiesthesia researcher wants to dedicate himself to the research of minerals, he will have, first of all, to master all the technique and all the elements that concur in the explorations he wants to do, as well as the surgeon, before performing operations, studies minutely all the human anatomy, and the pathology and the other branches of medical science, as well as the use of instruments, medicines, and whatever else is required to proceed safely in his operations. Therefore the pendulist (or the bacchettista) will procure, in the first place, a sample of as many rocks of minerals as he will be able to collect; or at least of those which may interest him most. Then he will study carefully and with the utmost precision the length to be assigned to the wire of the pendulum for each material. He will find this length very easily by making the pendulum plumb-line descend on the mineral under examination and lengthening the wire until the apparatus is set in motion, bearing in mind that it will turn in the direction of the hands of the clock when it is a metal body that is a good conductor, and in the opposite direction when the material is a bad conductor. Then for each body he will record the serial number of which I have already spoken. In this way he will be able to compile a list of the different materials examined, writing in the first column of the table the name of the mineral; in the second the length of the pendulum wire; in the third the number and direction of the rotations; in the fourth the Fundamental Radius, and so on; so that the operator will always have at hand a sure guide that will allow him to identify one body from another. In order not to force the reader to search in the pages already passed what I have said about the serial numbers, and since he will have begun to grasp the dowsing criteria and procedures, I will repeat here, summarily, the explanation of the said serial numbers. When you have well adjusted your pendulum in weight and length, suspend it with one hand over any body. It will begin to rotate in one direction and in the other, and as long as you do not stop it, it will continue its motion without ceasing. Therefore, interrupt its rotation with a shake of the hand. You will see that your apparatus will oscillate for some time and then spontaneously begin to rotate again, but this time in the opposite direction to the previous one. But these new rotations will be of a limited number that you will count carefully because it constitutes a series. Every body has its own number of series. Thus the series of electricity and magnetism is 10. A series of rotations may be right- or left-handed; but the number of series is always

identical for the same material or substance. Here I must again state that the one who reached the highest peak in this field of calculation and technique was the oft-mentioned Abbot Mermet, followed by other very talented disciples such as Viscount Henry de France, René Lacroix, Hector Mellin, Benoit Padey, L. Turenne and several others. The student dowser will have to train himself for a long time in these exercises to acquire the necessary practice, the confidence of the operator to get the best results; and he will not have to limit himself to use only the pendulum, he will do well to practice also with the wand, that perhaps will be, at the beginning, more difficult to use because it is not so easily adjustable as the pendulum. For the good use of the baton I again recommend the utmost care in holding it so that it may be freely raised or lowered. According to Viscount Henry de France the serial numbers of some bodies are as follows:

Crete 3

Oil 24

Silicon 5

Iron 4

Stoneware 6

Copper 5

Peat 6

Zinc 6

Hard coal 18

Silver 7

Pond 8

Mercury 12

Gold 11

Lead 13

Manganese 11

Antimony 65

The minerals are found in superficial deposits, in alluvial deposits, or in strata or seams buried at greater or less depth. In the former we have, generally speaking, auriferous, stanniferous, etc., soils; in the latter, fossil carbon and some ferrous minerals. Almost always a seam is nothing more than a mass of various materials deposited in a fracture of the earth's crust. It is enclosed between rocky walls covered with layers of clay called salbande. The upper part of the rock that covers the seam is the roof while the lower part is called the wall. The thickness of the seam is called power; but this is often variable even if very long. The veins of concretions, being the result, as I have said, of fractures in the lithosphere, are frequently found with an inclination that is very close to the vertical and since the aforementioned fractures are sometimes radial, it follows that the veins cross each other in several directions constituting the fracture field. Most of the minerals heaped up in these underground cracks are galena, blende, iron pyrites or copper pyrites. Now let us suppose that we should have to look for a deposit of galena. It is evident that if we were to inspect the whole area where we believe the mineral may be, it would take days and days, and weeks and months: that is, an enormous amount of time and considerable expense. Here we have to resort to Tele-radiesthesia which miraculously comes to our aid, I would say almost, allowing us to find, on a simple topographic map of the locality to be studied, and in a few hours, maybe in a few minutes, the precise location of the deposit that interests us. I have already said how to proceed. Make yourself a pendulum with a cloth bag in which you will have placed the mineral you wish to find: in our case, a little galena. Tie the wire that holds the bag to the end of a wooden stick that will allow us to regulate the length of the wire. Slide the pendulum slowly over the paper while keeping your other hand steady on the paper. When the pendulum turns you will already have an indication of the point to be dug; or, keep the pendulum suspended always on the same point and with the other hand, which will hold a thin wooden stem, make it run in every direction on the ground. When the point of the stem meets a deposit of galena, your pendulum will immediately begin to turn. Finally, there is another method: place a magnet on the plant and on one of its tips place a piece of galena. Make the magnet turn around itself, horizontally, leaving your pendulum to rotate in front of that witness. When the pendulum

oscillates you will have found the direction of the deposit. Move the magnet and repeat the same operation. Here you will have a new direction. The point of intersection of these two lines will be the one you are looking for. In the countryside you will be able to make the necessary checks and fix the perimeter of the deposit. Now let us proceed to a practical experiment, at home, where we are brought a piece of mineral of unknown nature. I place it on a table, where there are no other objects, and I also put there, one at a time, the samples of the different minerals that I have in my small collection. Then on them I will alternately present the pendulum, adjusted in length according to my sample, holding a finger of my free hand on the mineral to be examined and which I will have identified when the pendulum turns in the same direction and with the same number of rotations on both bodies. In the country the identity of two bodies is found more easily if one takes care to interpose, between the sun and the dowser who holds the pendulum and the witness in the same hand, the mineral to be studied. Among the many methods that are taught and praised for the identification of any body, I believe that the best is the one that resorts to the testimony because it is the safest and the one that gives the same results to all dowsers. The operator has, as we have seen, many elements on which to base his researches: the Fundamental Ray, the serial number, the testimonial, etc., so when he goes to a body identification, he has to use the testimonial. Therefore, when he goes to a given locality to discover a deposit, let us suppose of copper, he will have to know what the R. F. and the serial number of the copper are and he will have to be provided with a piece of sample of the metal that will serve him as a witness. Now, even if in the place where there is really a cupric seam there were, above or below this one, other mineral layers, such as bauxite, coal, etc., these layers will not influence the research of the dowser because, apart from the fact that he will concentrate his mind on copper, the identification elements at his disposal, for copper, will make him exclude all the other minerals existing in that locality. As for ascertaining the depth of the deposit found, the best way of establishing this is always either by counting aloud or by beating the ground with a foot at regular intervals, first establishing whether, as I have already said, each figure or each blow corresponds to 1 metre, 5, 10 metres, etc., or whether the depth of the deposit corresponds to 1 metre, 5 or 10 metres. And since we are speaking here of mineral research, allow me to expound a method for the quantitative analysis of the mineral under

examination and which can be carried out with the pendulum with greater rapidity and as much precision as with the most accurate chemical analysis. I refer here to the Probst system which operated as follows. He placed on a table the mineral to be examined and at a distance of about 35 cm from it, he let fall, slowly on the table, some powder or metal filings contained in the piece of mineral that he wanted to analyze, while he kept suspended on this the pendulum which ceased to turn when the amount of powder or metal filings corresponded to the content of the identical metal contained in the mineral. Among the thousands of experiments of this kind performed with complete success by Probst, I will mention one: one day he was presented with a fragment of ore still dirty with earth. This fragment weighed 320 grams. On the pendular analysis made by Probst there were:

iron oxide grams 262

manganese 4,52

land and waste 53.48

Then it was desired that he should specify the quantity of pure iron contained in the ferrous oxide; and he found, using pure iron as a witness, that the oxide contained 165 grams of this metal. Sometimes a mineral contains different metals. In order to distinguish them, it is necessary here also to have recourse to a series of tests with a greater or lesser number of witnesses according to the case. With the above method he also analyzed wine and milk. He proceeded as follows: he took two glasses perfectly similar and placed them on a table in the same vertical plane. In one of them he put a certain quantity of wine or milk, and in the other he slowly poured water, keeping the pendulum suspended above them, which continued to turn until the quantity of water poured into the glass

corresponded to the precise quantity contained in the wine or milk. Obviously, in the research of a metal or in the analysis of a mineral, the greatest difficulty often lies in obtaining the witness when it is a question of precious metals (gold, silver, platinum, etc.).

Thermal, mineral and radioactive waters. - The search for these waters will be made like that for drinking water or minerals, using witnesses. Often the waters of which I speak are so-called fracture waters because they spring from great depths and, through the cracks due to the fractures in some layers of the earth's crust, they rise to the surface of the globe, losing a great deal of their original heat. Therefore, if we wish to have these waters endowed with a higher temperature, it is necessary to perforate the ground so as to approach nearer to their source. But it must be borne in mind that the waters that spring from the ground seldom reach it more or less vertically from deep springs. The waters follow various ways through the fractures of the lithosphere and then they channel themselves in permeable layers enclosed by other impermeable layers. Therefore the dowser will have to search for the same source going up toward it with his pendulum or with the stick in hand, together with the witness of the water to find.

Underground cavities. - Everyone knows that there are many cavities in the subsoil, which may be natural or due to the hand of man. The first were produced either by water; or by telluric movements, etc.; the others can be considered as dwellings or as shelters of our most remote ancestors. In order to carry out their reconnaissance Henry de France advises you to take an internally empty pendulum, in which, if you have it, you will place as a witness a little of the soil belonging to the cavity to be surveyed. The length of the wire of the pendulum will be 34 cm. Walking through the countryside with your pendulum in your hand, it will begin to rotate when you arrive at the edge of the underground void and will continue to rotate until you reach the other edge. Of course you will have to cover the ground far and wide several times to establish, from above, the boundaries of the cavity. If, instead of the pendulum, you use the rod, it will rise or fall when you are standing on the cavity. By tapping with your foot at regular

intervals in the usual manner, you will also know its depth. Even a well that has been filled up gives off very clear radiations that make it easy to find. The same can be said for catacombs, of which one can guess the number of floors, the development of the galleries and those still empty and those filled in either by landslides or by human work. For the search of tunnels, catacombs, etc., some people like to use, as a pendulum, a vial or an empty and closed bottle. This sort of pendulum will continue to swing as long as you are above the tunnel. As soon as you leave the gallery it will cease to rotate or will oscillate negatively. You can also use another method: use your usual pendulum, but keep in your free hand the vial or bottle I mentioned earlier. The results with this system will be identical to the first. In any case, whichever method is used, it is possible, with a little practice, to trace from the outside the whole course and dimensions of the underground passages that are to be measured, and even the steps for ascending from the depth of the underground to the surface of the ground.

Archaeological leftovers. Treasures. - For these one operates in much the same way as for the search of the cavities or tunnels of which I have spoken before, because especially the archaeological remains are almost always found in more or less vast and deep subterranean areas. There have already been countless archaeological discoveries made by means of the pendulum, and I need only mention those of Mr. Pierre Morin at Limoges; those of Mr. Merle (of whom I have already spoken) at Villefranche-de-Rouergue; those of Mr. Raymond Cabrignac at Roque-Rouge in the Lot, and those of Messrs. Treyve, Guérin, Randon, etc., etc. As we can see, even in this very important field, which is that of the history of Humanity, Dowsing can make such a contribution as no other science can give us. Why, then, should we not make use of it?

Part Four

Dowsing applied agriculture

Also in the agricultural field Radiesthesia can be of infinite usefulness and since, being an old farmer myself, I know how many difficulties are often met in the practical application of the agricultural science, so vast and so complex, I think it is opportune to dedicate to this part of my work some pages that I hope will be read with pleasure by those who deal with rural things and that I hope will be of some profit to them. Several scientists and authors have already dealt brilliantly with this branch of dowsing and I remember among others: Dr Larvaron, professor of agriculture at the Agricultural Institute of Rennes (France), Viscount Henry de France, General Lemoine, Father Bourdoux and especially Hector Mellin who may be considered the pioneers of this science. I have said elsewhere that all the bodies vibrate or emit irradiations in a direction that is proper to them and that such irradiations attract or repel, associate or destroy. The Radiesthesiologist who enjoys a discreet sensibility, by means of his apparatuses (wand or pendulum) can perceive them and specify their direction by going around them. Therefore, if we can determine the direction of the radiations of a body, it will be easy for us to establish the analogy between different bodies or the discordance existing between those that may seem to us apparently similar. Thus we are given the possibility of ascertaining whether a quality of soil radiates in the same direction as a manure, a plant, a seed, etc., or whether it radiates in the same direction. If, therefore, the aforesaid soil radiates, let us suppose, towards the North-East, we will have to give it a fertilizer and give it seeds that emit radiations corresponding to those of the soil in question. We will see now the infinite resources of Radiesthesia also in this branch and how to proceed.

1° - Study of soils. - In dealing with agriculture, we must begin, of course, with the study of soils, that is, their quality, composition, etc.. The agrarian soil is generally composed of four fundamental elements which are:

the sand (silica), of which the Fundamental Ray turns to the East (fig. 25);

the clay, with the R. F. facing south; the limestone, with R. F. facing north; the humus, with R. F. facing west.

These elements may be all present in a certain soil, or they may be partly in excess, or completely lacking. Now, it depends precisely on their ratio that a soil is more or less fertile, or that a plant can more or less well vegetate in it. On the other hand, we must bear in mind that since an agricultural soil is a compound of the above-mentioned various elements, the different Fundamental Rays emanating from them will be grouped in such a way that the largest component will have the predominance over the others. To find, therefore, the true nature of a land to be analysed we proceed as follows: we take a sheet of paper (fig. 45) and on it we draw the four cardinal points. By means of a compass or any other means we will orient the aforesaid sheet so that the North-South line drawn on it actually corresponds to the direction of the magnetic needle. In the centre of the sheet we make a pile of the ground of which we wish to know the nature, and around the windrose thus drawn on the sheet we make the pendulum or the rod circulate slowly. When these apparatuses will be in front of the cardinal point corresponding to the R. F. of the body under examination we will see the pendulum begin to turn positively or the stick to straighten energetically. Thus, if in the center of the windrose we have placed some siliceous soil, the pendulum or the stick will react when they coincide with the East; if we have placed some clay, they will move in front of the South, and so on, as I said before. Wanting to operate with greater care, take as many glass specimens as there are soils to be studied, and in each of them place a sample of each quality of soil, closing them with corks; and to avoid any autosuggestion the operator must not know, when making the experiment, which is the soil contained in the respective specimens. In order to recognize them, when the work is completed, he will be able to write on the inside of the cork a letter or a number, which will allow him to identify

them. Instead of the loose material, he will put the tube containing it in the centre of the compass rose.

figura 45

If the material to be analyzed were composed of the four aforesaid elements in equal parts we would have the reaction of the apparatus at the four cardinal points: and this is obvious. If we have a mixture of 50% clay and silica, we will have the reaction in the North-East; if the mixture is 50% clay and silica, the apparatus will give us a clue in the South-East, if of clay and humus, in the South-West; and finally if of limestone and humus in the North-West. Naturally the influence of each of the four elements is felt for a certain amplitude of arc: 30° . Thus:

the limestone radiates from the North-Northeast to the North-Northwest;

the silica, east-northeast to east-southeast;

the clay from the south-southeast to the south-southwest;

the humus, from the West-Southwest to the West-Northwest;

silico-calcare radiates east-northeast;

the siliceous-clayey radiates east-southeast;

the silico-humiferous radiates to the southwest;

the clay-limestone radiates to the southeast;

the clayey-sandy radiates to the south-southeast;

the clay-humiferous radiates to the south-southwest.

At this point I must call the reader's attention to what I have already said about colours, completing those hints with these other indications and observations:

purple is north;

turquoise corresponds to the Northeast;

the green corresponds to the East;

yellow corresponds to the southeast;

red corresponds to the South;

black corresponds to the Southwest;

gray corresponds to the West;

white corresponds to the northwest.

Now if we relate colours to the qualities of soils, we will see that a colour can very well serve as a testimonial for the identification of a soil as of a mineral. And, that is:

North = Purple = Limestone;

North-East = Thurkey = Silica-calcare; East = Green = Silicea;

Southeast = Yellow = Clay-Lime; South = Red = Clayey;

Southwest = Black =Silico-humifera;

West = Grey = Humus;

Northwest = White =Calcare-umifera.

But in order to understand well the denomination of the said lands, I deem it proper to refer this denomination to the centesimal composition of the lands, as may be seen from the following table which I take from H. Mellin's book:

Natura dei terreni	Argilla e sabbia fina %	Sabbia %	Calcare %	Humus %
Terre franche	da 20 a 30	da 50 a 70	— di 5	da 4 a 10
» argillose	+ di 40	— di 50	da 5 a 10	» »
» argillo-calcaree	+ di 30	— di 50	» » »	» »
» argillo-sabbiose	» » »	da 50 a 70	— di 5	» »
» argillo-umifere	» » »	— di 50	» » »	+ di 10
» silicee	+ di 10	+ di 80	— di 5	da 4 a 10
» silico-argillose	da 10 a 20	+ di 70	— di 5	» »
» silico-calcaree	— di 10	» » »	da 5 a 10	» »
» silico-umifere	» » »	» » »	— di 5	+ di 10
» calcaree	» » »	da 50 a 70	+ di 10	da 4 a 10
» umifere	» » »	— di 50	— di 5	+ di 15

Depending on their composition, soils are divided into three broad categories:

1° - Alkaline or basic soils; those in which limestone predominates;

2° - Neutral soils, in which the components are balanced with each other;

3° - Acidic soils, in which humus prevails (former marshland or reclaimed land).

Way to check soil analysis. As seen, each soil quality has a corresponding color. Therefore:

1° - Since a given colour gives off the same radiations as a given ground, if we take an object of that colour (paper, cloth, or other) and hold it in the same hand with which we hold the pendulum, in the guise of a testimonial, our apparatus will turn on the ground corresponding to the colour of the said testimonial.

2° - If we place before the two points of a magnet having the form of a horseshoe a pile of earth and an object coloured with the colour corresponding to the earth itself, the pendulum, suspended between these two bodies, will begin to turn.

3° - By arranging the colours around the windrose in such a way that they correspond to their irradiations and by placing, in the centre of the windrose, a sample of the earth to be harmonised with the respective colour, the pendulum will turn even as it passes between the sample of the earth and the tuning colour.

Once we have been able to know the precise composition of a land by means of the procedure indicated above, it will be easy for us to modify it by following the same procedure.

2° - Study of the fertilizers. - One of the fundamental canons of theoretical and practical agriculture is that of identifying the most suitable fertilizer for a given soil and for the type of plant to be cultivated in it. The majority of cultivators (and I do not say farmers because the true farmer is he who unites science with practice) do not care to analyze the land they work; they do not care to investigate which is the most suitable fertilizer for the cultivation they want to do. The empirical cultivator (and how many there are!) has heard that such a nitrogenous fertilizer has given splendid results for a given crop. Great! And here he is spreading that same nitrogenous fertilizer with full hands over his field, without caring whether it is suitable for his soil and the plants he grows in it. Tomorrow he will get a nice fiasco, and here he is again, this time, on a crusade against that fertilizer that he had purchased and used with a fervor as enthusiastic as wrong and foolish! Many, unfortunately, believe, in their ignorance, that agriculture is all based on practice and that agricultural science is perfectly useless. This is a great mistake, because, as I have already said, very few branches of human knowledge require such a vast amount of deep knowledge and vast doctrine. A good agronomist must, or at least should, know botany, chemistry, physics, agricultural mechanics, etc. etc., and our great Pietro Cupprai was right when, from his chair in the University of Pisa, he told his students: "Remember, young men, that in agriculture, theory without practice is nonsense; practice without theory is madness". Therefore, the knowledge of the

use of fertilizers is one of the essential conditions, capital for the success of an agricultural enterprise of any importance, because a fertilizer badly adapted or badly administered, causes two damages:

1° - that of ill-spent money;

2° - that of the diminished harvest.

In order to facilitate this task to our rural people, I will speak here, briefly, of the means that Radiesthesia puts at their disposal for the truly rational employment of the natural and artificial fertilizers that are available today. By natural fertilizers we mean those produced by the dejections of men and animals, by urban wastes, by rubbish and green manures; while chemical fertilizers are those we owe to the chemical industry. In the administration of fertilizers we must take into account, as I have already said, the nature of the soil and the quality of the plant to be grown. The problem, therefore, is not always easy to solve: for a soil may require a given element and refuse another. Therefore the use of compound fertilizers is not always advisable, unless it is previously well studied. And an excellent and precise method of study is provided by Dowsing. How does it work?

In the same way adopted for the soils: it is necessary, that is, to find, first of all, the direction of the rays emitted by the fertilizer to be administered. To do this, we will resort to the usual wind rose (fig. 45). We will bring in the central circle a small quantity of the fertilizer under examination, either dissolved or enclosed in a paper bag, or, better, in a glass sample, and, making the pendulum suspended from one hand, run along the entire external circumference of the compass rose, we will end up finding that point in which our apparatus will turn. Naturally, this direction of irradiations will also correspond to that of the irradiations of a ground and

of a colour. Thus, to cite an example, if we have placed, in the center, a Nitrate (of Lime, Soda or Potash) the emanations of this fertilizer will radiate in a South-South-East direction. Now in this same direction the emanations of the clay-sandy soils also radiate. It is obvious that, instead of looking for the soil which corresponds to a certain fertilizer, it is more logical to do the opposite operation: that is, always working in the same way, to find the fertilizer that a soil requires. In any case, it is always a good idea to check the result obtained in the following way: place in line with the axis of a horseshoe magnet, or with the blocked needle of a compass, a pile of earth and one of the chosen fertilizer, about 30 cm apart. Then, keeping the pendulum suspended between the two bodies, so that the apparatus is equidistant from them, it will be observed whether it remains stationary or turns. In the first case the two materials do not agree with each other; in the second case, however, one is perfectly suited to the other (fig. 39 and 40). As a general rule we can consider that:

the acid lands radiate in the sector between West and Southwest;

the strong lands radiate in the sector between South-Southwest and South;

the semi-strong lands radiate in the sector between the South and the South-South-East;

the lean lands radiate in the sector between South-South-East and East-North-East;

the barren lands radiate in the sector between East-Northeast and North.

Since not everyone knows how to judge, at a glance, the value of agricultural land, which can mislead even an expert, I invite the reader to whom the present notions may be of interest, to resort to the method I have exposed and which is not really difficult to carry out, in order to quickly know what is the nature or quality of the land he must analyze. In order to make the analysis more convenient and quicker, the scholar may keep under his eyes figures 25 and 45, from which the orientation of the radiations of each soil is immediately evident, as from the following picture we have that of various fertilizers and other products of interest to the farmer.

To the East-South-East radiate: potassium sulphate - calcium sulphate - potassium chloride.

In the South-South-East they radiate: calcium nitrate - soda nitrate - potash nitrate - sodium carbonate - lithium carbonate - sylvite - whale manure mixed with bones - pig manure.

To the North-Northeast they radiate: copper sulphate - Thomas slag.

To the East-North-East radiate: iron sulphate - calcium bicarbonate - gypsum.

In the South-East they radiate: sodium chloride - nitric acid - phosphoric acid - animal horn debris.

In the South-South-West they radiate: ammonium sulphate - mineral phosphate - mineral superphosphate - bone superphosphate - calcium cyanamide - horse manure, or manure - sheep manure.

To the Southwest radiates potassium phosphate.

In the South it radiates: manure, that is, cattle manure.

Of course, there are some fertilizers that must be used alone and others that can be mixed together, either when spreading them on the ground or some time before.

With the pendulum it is possible, therefore, to establish not only the compatibility of the fertilizers with the suitable soils, but also the incompatibility of some fertilizers with others. It is sufficient, as I have already said, to suspend two fertilizers, placed in heaps on a table at a distance of 30 cm from each other, to see from the movements of the pendulum if they can be mixed without damage to the crops or without neutralizing each other. If it is necessary to proceed with the analysis of the soils that make up a farm or an estate, as many samples should be taken as there are different varieties of soil visible on the surface, and these samples should be in proportion to the size of the farm or estate.

3° - Study of seeds and plants. - As we must study the agreement, the harmony (I would say almost) between soils and fertilizers, so we must also study the quality of the seeds and plants that we want to entrust to the soil of a given place. From the examination of the seeds we must know two things:

1° - if the seeds still retain their germination capacity;

2° - whether they are suitable for the soil prepared for them.

Regarding the first point, the desired answer is not so easy to obtain because everyone understands well that, dealing with very small seeds, such as those, for example, of clover, alfalfa, etc., one cannot, certainly, think of passing them with the pendulum one by one. Therefore, the best method to follow consists in obtaining a small quantity of seeds, of the same nature of what you want to sow, but that this small quantity is really selected and of sure germination. Once in possession of this element it is placed on a table at a distance of 30 cm from a small heap similar to the seed to be examined, taking care however to place these two small samples in the line of their irradiation: that is, orienting the alignment that they form according to the direction of their emanations. So if we examine the clover seed, we will put the two piles or sacks of seeds in the direction South-West. Then, keeping, as usual, the pendulum suspended between them, we will see if it will turn positively or negatively. From which we will be able to draw our conclusions. But it could also be, however, that its turns were weak or restricted. This would lead us to believe that in our sample of seeds to be thrown into the ground, only a part of it was good. It would then be a question of establishing what percentage of germinability this sample has. In this case we will have to resort to the system which I have already indicated and which gives good results.

Write on a sheet of paper a series of numbers: 1 - 5 10 - 15 etc. etc.. Then, holding the forefinger of the free hand outstretched like an antenna over the pile of seeds, present the pendulum, successively over each of the numbers written on the sheet of paper, while mentally the speaker asks: "What percentage of germinability do we have? One, five, ten, fifteen, etc.?" The

pendulum will remain motionless until it is on or near the number corresponding to this germination. It may be that it will swing, with large and dense rotations, for example on 80. This will mean that the percentage sought is 80. But it can also be that it rotates weakly on 80 and 85. If you want to know precisely, write on a card: 80 - 81 - 82 - 83 - 84 - 85 and try again with the pendulum. We will find with mathematical precision the degree of germination of the seed we have. Having known this first result, we must now know if this seed is suitable for the soil in which we would like to sow it. To obtain a positive answer we will operate as we have indicated several times and as we have also said above for the examination of seeds. We will have, however, also in this case, several pendular indications. The first one will be given to us with wide and fast rotations: the ground suits the seed perfectly. The second will be manifested by rotations in the same direction as before, but the rotations, instead of tending to widen, will fade away, little by little. These will tell us that the soil is quite good, but that it requires heavy manuring. Finally, it could happen that the pendulum turns negatively: the soil does not suit the seed. Recapitulating what we have said so far and what we have indicated in fig. 25 we know that in the direction of the:

South-Southwest to the South radiate: wheat, oats, sugar beet, and fodder legumes - the color black, and also partly red - the humiferous soil (clay-humiferous) - mineral and bone phosphates and superphosphates.

East-South-East to East radiate: the corn and barley - the green and yellow colours - the siliceous-clayey soil - the calcium sulphate, potash chloride and potash sulphate.

East-North-East to the North radiate: rye - purple and green - silica-calcareous soil - gypsum and calcic bicarbonate.

Southwest radiate: clover - black - silicoumiferous soil - potassium phosphate.

South-East radiates: hemp - yellow - clay-calcareous soil - phosphates and nitrates and so on: we could lengthen the list; but I think that what I have written is enough to give a fairly precise idea of the theories expounded, which can also be applied to trees and not only to herbaceous plants. We have often seen trees that have been repeatedly planted in the same soil in the hope that they would eventually take root and develop vigorously perish rapidly. Now, operating as I have already said, but taking for examination a little of the soil in which you want to plant the tree, and a branch or a root of it, we will know without fail if they harmonize with each other and if, therefore, the planting can be carried out in that planned land.

Another research we can do with our pendulum is to know quickly the state of health of a tree. Put your free hand, with your fingers outstretched, close to the tree and, with the other hand, hold your device close to the trunk. You will see it turn in a positive direction. Now, turn yourself around the tree always holding your hands in the indicated way. Suddenly you will notice that the pendulum does not rotate anymore, but that its turns become oscillations. This will show us that at that point the plant is sick or dead. Instead of the pendulum, the same research can be carried out with the chopstick by running the tip along the circumference of the trunk. From these brief hints it is evident how many services Dowsing can render, directly or indirectly, to agriculture. Let's not mock this new and wonderful science which, like a new bride still wrapped in her chaste and virginal veils, waits for the bold and desired man to come and tear or remove those veils that still hide the most intimate beauties of the beloved woman. Such is science for him who makes it his own idea, and who, before conquering it, suffers and fights. I do not believe that the readers, or at least the majority of them, will be persuaded by the theories presented, the examples cited and the facts narrated. I know well how difficult it is to inculcate in others their faith, and teach new ways to go, because the novelties always arouse fear and distrust until such novelties have not been consecrated by

time and long experience. However, I hope that these poor pages of mine may arouse, at least, a little curiosity in some of them and that, at least, some tests are made, some attempts. It's enough for me, because these experiences are so interesting that, once started, you can hardly give up. The applications are so many and so varied that those who devote themselves to them, at first as a joke or out of simple curiosity, end up becoming passionate about them with the most tenacious fervor. And although it is not good for the human organism to devote itself to these exercises in a too continuous way, I know that the use of the pendulum will end up grabbing the reader as others let themselves be won by the passion for the game of cards, billiards or or crossword puzzles.

Weather Forecast. - Open the left hand in the form of a very open pincer, as in Figure 50, and hold the pendulum suspended in the center of the arc formed by the fingers. Three main cases will be given:

1° - the pendulum will swing towards the index. This will tell us that the weather will break down and be bad;

2° - the pendulum will swing towards the tip of the thumb: in this case the weather tends to the beautiful one;

3° - the pendulum will oscillate towards the inside of the arch, that is towards the junction of the bases of the thumb and index finger: and this will be a sign of variable time.

If this last oscillation tends towards the base of the thumb, the variable will be mainly directed towards the beautiful, while it will be the opposite if the

pendulum oscillates towards the base of the index finger.

Part Five

The witness bag of Rev. Father Bourdoux and his cares

Rev. P. Bourdoux, whom I have quoted so many times in the course of this paper, since he has been one of the many sources from which I have drawn what little I know about dowsing, is a pious, very learned French missionary who spent most of his noble existence in the endless, unknown and fearful Brazilian region of Mato Grosso. And living in almost desert areas where he exercised his sacred ministry, in a territory so vast that the parishes were hundreds of kilometres apart, he began to make use of Dowsing, in a thousand of its applications, to facilitate for himself and his brothers the task that hung over them and, above all, to come to the aid of the indigenous populations entrusted to their care. And among the many material benefits, in addition to the moral ones he brought them, there was also that of health care. But this was opposed by canon law and especially by civil law. For it is well known that ecclesiastical laws forbade priests to practice medicine. However, there have been great saints, high prelates and even popes who have shown themselves, in certain cases, to be even favourable to the medical intervention of the clergy, especially the missionary. The Encyclical *Rerum Ecclesiae* of His Holiness Pius XI, dated February 28, 1926, in which he affirmed the importance of medicine at the service of the Missions, is still of recent memory. Indeed, in some seminaries and convents today the study of medical disciplines is admitted. Now, in the course of his long and daily peregrinations through the Mato-Grosso, and through the infinity of compassionate cases that Father Bourdoux encountered in the exercise of his ministry, he became acquainted with a number of medicinal plants, of extraordinary efficacy and which were indicated to him by those still primitive peoples who, perhaps from their origins, treated and cured themselves only with leaves, flowers, fruits, roots, etc., of the very rich flora of their regions. Father Bourdoux collected as much as he could of these plants: he catalogued them; he established for each one of them the disease it cured, the way to administer it, etc., etc. And when he had completed all the collection, he formed a small collection that he enclosed in as many small bottles or tubes as there were vegetable essences put together and which he then placed in a special case (trousse) which he made his inseparable travelling companion. The case comprised

50 or more phials, numbered, containing, each, a variety of plants represented by leaves, seeds, pieces of roots, or branches, etc. Father Bourdoux called it Trousse-Témoins, that is to say, a witness box, because each tube with its contents represents a witness, or rather the most suitable plant for the cure of a given disease. These boxes, already prepared, are sold in Paris at the House of Radiesthesia (Rue Saint-Roch, 16); but with a little patience and good will, I think that everyone could make them himself, using small glass samples, closed with a cork. The greatest difficulty is that of obtaining the necessary vegetables. However, these can also be found at herbalists. Naturally, it is necessary to respect industrial privatisations and to see, first of all, by which patents the invention of the Rev. Father Bourdoux is protected in our country. How is this Trousse-témoins to be used? Here are the inventor's instructions.

"Open your Trousse and place it on your work table, and to your left. Then take the pendulum and suspend it on the hand (or also on the photograph or on a writing) of the sick person, while you will place the point of the index finger of your left hand on the tube N. 1 where you will leave it more or less long, according to your dowsing sensibility. If after a few moments of waiting the pendulum does not move in any sense, pass to the tube N. 2, then to N. 3, and so on until you find the one that will make to turn your pendulum or according to the course of the spheres of the clock or in opposite sense. But remember that turning in the first (right-hand) direction is good; conversely, turning to the left is unfavourable. Therefore, in the first case, the medicine that causes the rotations is good for the patient; in the other case it would be harmful to him, and the wider the circumference described by the pendulum, the more propitious or more harmful will be the medicine contained in the phial. When you have found a favorable one, do not neglect your researches; but continue to interrogate the other tubes to the last, because sometimes it may happen that more than one medicine is needed for a given infirmity, and that it is necessary to resort to a combination of two or more substances. To check this, take in your left hand the vial that has caused the large rotations and begin the experiment again. If these rotations are as large as before in the favorable direction, without leaving the tube, touch, always with the finger of the left hand, the

other vial that also gave rise to right-handed rotations, and carefully observe your pendulum. If its rotations do not diminish, but tend, on the contrary, to widen, this will mean that the two medicines are well harmonized between them for the disease you are examining, and can be administered at the same time. On the contrary, if, when we touch the second medicine, we see that the gyrations diminish or cease, we will conclude that the two medicines must be taken separately. For by this procedure you will learn that, often, two or more remedies which are beneficial if taken separately, become harmful when absorbed together or in the form of mixtures. In the Trousse, in correspondence with each tube, there is a label indicating the disease corresponding to it: thus you will see written: cancer, tuberculosis, syphilis, etc., etc. You will thus see written on it: cancer, tuberculosis, syphilis, etc. Thus, when you visit a sick person in this way, you will know at once what disease he is suffering from. From what I have said here, it will be evident to everyone of what enormous usefulness the pendulum can be also in the medical field: this induces me to believe that a day will come when all doctors will use it continuously".

This prophecy of Rev. Bourdoux is already being fulfilled because I myself know some very skilful doctors who nowadays make their diagnoses by means of the pendulum which gives indications of absolute and precise truth. Sometimes, indeed, it disagrees with the opinions of doctors, but always ends up being right. Once we have found, by means of our small apparatus and the Trousse-témoins, the nature of the disease and the corresponding remedy, contained in one or more tubes, we must determine the quantity of the remedy to be administered either in drops or in tisanes or decoctions. These are of more energetic action, but often dangerous if they are made especially with parts of plants containing toxic principles. In any case, if you want to know what dose of a decoction can be given to a sick person, proceed as follows: with the left hand, as usual, touch the plant or plants with which you want to make the infusion to be drunk by the sick person, and with the right hand hold the pendulum over the hand (or some object) of the sick person.

Then, after having mentally established the unit of measurement of the medicine (centigram, decigram, gram, etc.), the operator will ask: "should this patient take 1 gram, 2 grams, etc.?" He will continue to count (as we said when we spoke about water research) until the pendulum will say "Enough!" with its different movement or with the stop of the gyrations or oscillations.

In more or less the same way the number of drops of medicine to be given to the sick person is determined. After having identified the tube containing the best remedy for him, one takes this tube in the left hand, doing as I said for the tisane, and asks "how many drops shall I give? One?... Two? Three? etc. etc.". Sometimes the pendulum will turn immediately, which means that one or two drops will be enough. Sometimes the pendulum will spin for a long time before stopping and will tell us that the number of drops to be swallowed is high. Finally, a third case may occur: that is to say, after you have found the right medicine, when you are counting the drops, when you are dosing them, your pendulum, from the first drop, starts to turn in the opposite direction; that is, to the left. This left-hand rotation lets us know that a single drop is already too much for our patient. It will be necessary to give him only a part of it: $\frac{1}{2}$, $\frac{1}{3}$, $\frac{1}{4}$, etc. The precise dose will always be obtained by questioning the pendulum. Let us suppose that the pendulum tells us to give $\frac{1}{5}$ of the dose. How to divide a drop into five parts? It is very easy. Dilute the drop in five spoonfuls of water, mix well, and give the patient one spoonful of the solution. Now, according to a great many experiments carried out by Father Bourdoux and his missionary confreres, this phenomenon has been observed; that often a sick person could not swallow more than a fraction of a drop of medicine. Then, as his health improved, he could absorb more and more of it, until he was completely cured. How can this fact be explained? The question finds its ready and natural answer in that it occurs constantly every day. For if we were to give to a child of a few years old what we give to an adult man, the child would evidently succumb under such an excessive load of food. On the contrary, if we increase the food gradually according to his development, we will only facilitate this development and strengthen the whole organism. And so it is with the sick, to whom medicines should sometimes be administered

gradually according to the indications of the pendulum, for it will enable you to establish the tuning between the healing power of the remedy and the capacity of its absorption by the sick person. As can be seen from these brief remarks, the Bourdoux cure has nothing to do with allopathy, nor with homeopathy, because diseases are not treated with medicines which produce, in a healthy body, effects contrary to the diseases themselves, or with remedies which destroy the symptoms. This new therapeutics is based exclusively on the resources offered to us by plants, and on the way of having them ingested by the sick. I have hitherto spoken of the administration of the remedy contained in a single tube; but I have already said that sometimes two or more qualities of such plant remedies may be required. We know how to choose and dose them by studying them separately. Let us suppose that the pendulum has indicated to us the vials N. 5, N. 9 and N. 15. If we examine them one by one, we find that we need 2 drops of tube No. 5, 5 drops of tube No. 9 and 3 drops of tube No. 15:

2/10 of tube No. 5

5/10 of tube No. 9

3/10 of tube No. 15

These tenths can be represented either by drops or by teaspoons or even by soup spoons. Having prepared the mixture in this way, try, with the pendulum, how many drops of it you will be able to make the sick person take. You will have an ideal cure. The efficacy of the above medicines, taken in an infinitesimal dose, is immense, incalculable, and, certainly, always much less dangerous than herbal teas taken in large doses. Sometimes, however, or for personal incapacity of the dowser, or for lack of time, it is not possible to have the precise dosage. In these cases one will

start with a single drop, increasing the number every two or three or four days, according to the state of the sick person. The drops should preferably be taken in the morning on an empty stomach and in the evening before going to bed, diluted in a little water. But there are also other ways of curing with the above system which Father Bourdoux called Poconéol. If the evil is localized, make tablets of it which you will apply for about an hour each time, in the morning and evening on the sore spot. To prepare these compresses, take a piece of gauze of appropriate size, which you will just moisten with water in which you will have poured a few drops of Poconéol according to the quality and quantity indications given to you by the pendulum. The compresses should be kept firmly in place on the diseased part by means of bandages. It is advisable to keep them rather warm. If the sick person cannot bear them for the prescribed time, they should not be insisted upon. Instead of compresses, one can resort to a light rubbing of the diseased organ with a hand wet with Poconéol. But the most effective of all systems of treatment (by the oral route or by tablets) is that of the bath. Using the method already described, look for the most suitable remedy in the Trousse-témoins; determine the exact quantity and pour this quantity into a bathtub where there is water, not too hot, capable of covering the whole body of the sick person. If the pendulum has indicated to you 2 or more substances from the Trousse, pour 20 drops, for each quality, into the bath and shake well the water contained in it. Then immerse the patient in it and leave him for 15 to 20 minutes, unless he is too tired. He will do well to wash his face and head with the same water. Dry him well with warm sheets and put him to bed so that he will not catch cold and you will notice that from the first bath, he will feel more relieved and invigorated and it will seem to him to feel oil coming out of the pores of the skin; and in fact if you look at the water of the bath you will see it of another color and on its surface you will notice some oily spots which are really produced by the detoxification of the organism of the sick person who was immersed in it. It is not possible to indicate, even approximately, the number of baths needed because they depend on the nature and gravity of the illness. By now one may ask what is contained in the famous little tubes that are sold in France under the name of Poconéol products. On this point it is necessary to understand: the witness tubes, contained in the portable case of Father Bourdoux, and which serve only as such, for the diagnosis of the disease, for the search of the appropriate remedy, are not to be emptied of their

contents which have a simple indicative office. In them are contained elements of plants (mostly exotic) crushed or pulverized. Each tube is distinguished by a number; each number corresponds to a variety of medicinal plant that, after the indications of the pendulum, you can buy from a herbalist or have prepared in drops or infusion by your pharmacist. It is however evident that, in order not to violate the sanitary laws of our country, the patient who wants to follow this method of cure, will have to ask for the intervention of a dowsing doctor. In Italy there are already some who have dedicated themselves to it with great enthusiasm and success. But also in this it is necessary to be precise. Radiesthesia is not a remedy or a cure; no. It only serves (as I have already said) to make the diagnosis of the disease and to find the most suitable medicine. Applying Radiesthesia to medicine, and I will speak about it later, and by means of his Poconéol case, Rev. Father Bourdoux and other religious of his Order and also some doctors (among whom there are Italians) have obtained truly prodigious healings in very serious cases of leprosy, syphilis, cancer, tabe dorsale, nervous tic, etc.; cases which he suffused with the help of the doctor, and which he has been able to treat with the help of the doctor. etc.; cases that he substantiates with names of people and places, with letters of cured patients and even of several health workers. Certainly we must not believe that with this system everyone can be cured. If this were so, we would have found the means of immortalizing our bodies, which is absurd. But the Bourdoux method, like all medical science, tends to diminish and delay mortality, tends to heal the healable, tends to diminish the sufferings of the sick and to alleviate evils in general.

The Bourdoux Method applied to veterinary medicine.

The Poconéol Witness Bag is not only useful for humans, but it is equally useful for the care of animals, whether they are birds or quadrupeds. From the timid turtle-dove to the biggest ox of Chianina breed, Poconéol is certainly of great, unquestionable usefulness for the breeder as well as for the veterinarian, always, however, used with the dowsing procedures I have often described. The operations to be carried out for the cattle are identical

to those to be practiced for ourselves; and therefore I will not repeat what I have already said. I will only warn the reader that to examine an animal by means of a pendulum it is necessary to suspend it on the animal itself; or on its back. In the absence of the animal we may have recourse to its witness, represented by a tuft of hair, feathers, urine, etc., or to its back. Among the diseases that most frequently and with the best results were fought I will mention foot-and-mouth disease. From numerous attestations, sent to Bourdoux by farmers and veterinary surgeons, it appears that, in the space of 15 or 20 days, the terrible epidemic disease was (in most cases) completely conquered. But besides these results, others were obtained, always in the veterinary field, with the method in question: for instance, that of finding vegetable substances which, when administered in decoctions or in drops, favour the development, the strengthening or the fattening of the animals of breeding, or even the production of milk or wool. Apart from the Poconéol Products (still not very widespread and not easy to find), Dowsing can be of great help to the intelligent and evolved farmer, for all that concerns his livestock: state of health, milk capacity of dairy cows, the most appropriate kind of nutrition, etc. etc. Concerning the state of health, I refer the reader to what I will say later on about Dr. Marty's quadrant, which can be applied both to men and animals in general. Concerning the possibility of knowing the dowsing capacity of a cow, here is how to proceed, according to Count Stefano di Robiano, from Marchin (Belgium): put the index finger of the left hand on the back of the cow, at half distance between the shoulder and the tail attachment, while holding the pendulum with the right hand. Slowly slide your left hand against the abdomen of the cow towards the end of the udder and note well the point at which the pendulum begins to turn. If it starts to turn in the first part of the path, that is, from the spine to the middle of the ribs, the cow will have little milk; if the device turns about $\frac{3}{4}$ of the circumference represented by the belly of the animal, it will give a good production of milk. If, finally, the pendulum will turn when the left hand of the operator touches the udder, we shall know with certainty that the cow will be excellent.

Feeding livestock. - This is one of the most serious problems for the breeder, because we know that feeding has several purposes: that of satisfying the

physiological needs of every being; that of fattening, of producing milk, wool, etc. It is evident that, according to the purposes to be achieved, feeding must be regulated and dosed with special criteria. It is evident that, according to the purposes to be achieved, the diet must be regulated and dosed with special criteria: thus the same rations will not be given to an ox that remains idle in the stable, as to an ox that is subjected to the heavy work of ploughing; a dry cow and a cow that gives 20 litres of milk a day will not be fed in the same way. And then it happens with animals what happens with men; not all individuals accept and benefit from the same food. So the good farmer will have to find with the pendulum which feed and in what quantity he will give it for each meal to his cattle. To do this he will arrange on a table many piles of fodder and feed; for example:

a fistful of alfalfa hay, a fistful of sainfoin, a fistful of natural meadow grasses, a fistful of oat straw or barley straw; a handful of oats, or barley grain; a little peanut cake, linseed cake, etc.; a little soy flour, corn meal, etc.; a handful of oats, or barley grain; a handful of peanut meal, flax meal, etc.; a handful of soy flour, corn meal, etc.; a handful of oats, or barley grain. Then, touching the animal to be fed with your left hand, pass the pendulum over each of the above feeds. It is very probable that the pendulum will swing over all of them, or almost all of them; but he will have to choose those over which the pendulum will have made the greatest number of rotations. He must now know what quantity of the chosen feeds he will have to give to his cattle. He will begin with the first, which, let us suppose, is hay. Still touching the animal (or even a tuft of its hair) with one hand, he will count aloud: one, two, three, four, etc., until the pendulum, which had previously remained motionless, begins to turn. Let us suppose that this happens when he has counted ten. This means that he will have to give 10 kg of hay to the animal. Similarly, he will work with the second feed indicated to him by the pendulum, which may be, for example, wheat flour; and if there is a third, such as soybean meal, he will always work in the same way, so as to have the precise formula of each ration. This procedure is as useful for a pigeon as for a turkey, for a pig or for a cow. It is only necessary to take care of making the research with the most suitable food for the animal in question, for it would certainly be perfectly absurd to

attempt such an experiment by proposing hay to a capon, or millet seeds to an ox. Let us now consider another application of the pendulum. A friend of mine, a wealthy rural proprietor, had a splendid sorrel horse, which of all the others he favoured. One fine day this horse began to limp, very markedly, from the right front leg. My friend, who is a great connoisseur of horses, believes that the lameness comes from the shoulder, while his groom believes it comes from the knee, which, in fact, seemed to be quite enfeebled. He called his vet who agreed with the groom and diagnosed a form of rheumatism, ordering strong rubbing with I don't remember which medicine. My friend was not too convinced about the diagnosis and was worried. He met me in the street and told me about the case.

"Well," I say, "let me see this horse of yours."

"Why," he replied, "are you also a vet?"

"Far from it! - I replied, "Let me see it out of curiosity. Who knows, however, that I may not be able to point out the evil to you."

"And how?..."

"Let's go see your quadruped."

And he led me in very little persuaded of the utility of my visit.

When I arrived at the place, I had the beautiful animal, which had great difficulty in walking, led out of the stable. I took out of my pocket my pendulum, which never leaves me a minute, and began the examination of the sick limb starting from the shoulder, which I touched with my left hand. The pendulum remained still: neither oscillations nor rotations. I went down with my hand along the leg up to the knee: nothing! No symptoms of pain. I went down further. To the knuckle: nothing. When I touched the hoof the pendulum began to move; when I touched the iron, my pendulum began to whirl.

"Have the horse lashed at once - I said to my friend. The evil is here in the hoof."

"Impossible," he replied.

"And then let him be ruined. The horse is yours; but I tell you again that the evil is in the hoof: between the iron and the nail."

So firm were my words and assertions, that the owner of the horse instantly called in the farrier, who immediately removed the iron, and we immediately saw that the cause of the limp was due to a nail which had been broken off, and which, coming out of the nail, was pressing and tearing the fleshy part of the foot. I will not tell you the wonder of my friend and his groom. They almost regarded me as a sorcerer. "What?! With that trinket you have found an evil that not even the vet had known?!".

Sex of birds and poultry. - It is not always easy to distinguish the male from the female in many birds, especially when they are very young, and often

you have to wait three or four months to be able to identify them. With the pendulum, instead, you can know it with the greatest promptness and absolute precision. In fact, if it turns positively both on the head and on the tail of the animal, it will be a male. If it turns on the head and oscillates on the tail, the bird will be female.

Part Six

Radiesthesia and medicine

Here I am, now, to talk about another of the many dowsing applications that, especially abroad, is spreading and imposing in the medical class because it proves more and more useful for the good of Humanity. But since it is a very delicate subject and of which I can have only a limited knowledge, since I have not covered the whole scale of medical studies, contenting myself with acquiring some fundamental principles and forming clear and positive concepts both through the reading of many books and discussing it with men of deep doctrine and wide views, I will mention it only in a general line. I cannot and I do not want, however, to omit to speak here of a true scientist of ours, as great as modest and, therefore, not sufficiently known in Italy, while abroad his fame is very diffused and his value highly appreciated: I mean Prof. G. Calligaris, from Udine, who, through his diagnosis procedure, almost belongs to the dowsing field, although his method is based on hyperesthesia sensations felt by the sick in the fingers of the hand and in the interdigital spaces. But this would bring us too much out of the sowing and therefore I limit myself to mention it only to show that also in Italy someone deals with these great problems with passion and intelligence. Therefore I will not speak, in these very modest pages, of medicine properly called, that is of its very high function, nor I will put my foot in its seed; and if there will be some disciple of Aesculapius who would like to devote some time to read this book, he should not frown and, even less, hurl me against his anathema, because I will limit myself to speak about Radiesthesia applied to medicine in a general and, I would say, almost indirect way, advising him, if he wants to know more and better, to read the works which diffusely and skilfully speak about it and of which there is the list in the bibliography cited at the end of this small volume. But it is evident that Radiesthesia is called to bring to the medical science an incalculable contribution in the investigation of the illnesses and in the methods of cure, because it allows to diagnose them, to specify their nature, to go back also to the past; to locate the evil in incubation and finally to search the most suitable remedies and to control their effectiveness. However, one should not believe that it is enough to hang any object from a thread or a string in order to form a pendulum and

with it research on a sick person in order to have a correct response. Heck! That would be too simple. I have already said repeatedly that even in this field of our activity, practice and exercise are needed. One does not become a dowser overnight, just as one does not become a doctor, engineer, pianist, etc. overnight. Besides, for the use of the Radiesthesia applied to the medicine, a good knowledge of the anatomy is necessary, because it is not enough that the pendulum turns on an external point of the human body, if who uses the apparatus completely ignores which organ is in correspondence of that point. If there are physicians who, without having ever experimented or seen this new system of clinical investigation, condemn it a priori, they prove to be unfit for their task, inferior to their mission and of a very narrow mentality, because before denying or admitting any act, phenomenon or theory in the infinite field of Science, it is necessary to have proofs and sure and positive elements in hand. Radiesthesia is not a utopia and true dowsers are not charlatans. I say: true dowsers not to confuse them with those who boast to be such, but in reality they are not. Also in dowsing there are unfortunately some charlatans as there are in medicine, in art, in literature and in every other field of the human knowledge. I will add that also the most experienced dowser must always use the maximum prudence in his operations and that he will never have to perform them in public for the reasons which I have already mentioned elsewhere. If he is not a doctor, but for his natural gifts has those special requirements that allow him to feel, with the pendulum, what escapes to the eye or to our other senses, he will have to limit himself to be a collaborator of the graduated doctor and he will never have to replace him, both to avoid moral responsibilities and to not incur in the crime of abusive exercise of the medical art. As long as the dowser, intelligent and educated, makes a diagnosis with the appropriate method, he does not do anything wrong, as he does not commit any fault by honestly criticizing a work of art, a political speech or the work of any professional, when he has the sufficient competence in the matter. On the contrary, he can, in a certain way, consider himself as a member of that admirable and beneficent family of medical doctors who try to soothe the physical sufferings of men and to heal their bodies, just as priests soothe moral and spiritual sufferings and heal our souls so often tormented by the most cruel diseases and by the most bitter wounds. But the non-medical dowser must limit his work to diagnosis only, and never order or advise cures or remedies. He can do this

only if he is requested to do so by a qualified physician and if he acts in the presence of the latter.

Dowsing examination of the sick person. - This examination can be made as much directly on the sick person as on a photograph, a lock of his hair or on some object belonging to him. The methods to follow are different according to their inventors: Turenne, Bovis, Lesourd, etc., and maybe every way is good but always in relation with the operator because in Dowsing there is nothing absolute. Dowsing is not a purely mathematical and regularly positive science for which $4 + 4$ make 8 all over the world and for all humans. No; it depends very much on the individual who practices it. Thus for some the positive results from the rightward swing of the pendulum, while for others it is represented by oscillations perpendicular to their chest. Each one must therefore establish with precision from the beginning of the use of the pendulum, its polarity and the meaning of each movement of his apparatus, as each one must know exactly the characteristics of this: weight of the pendulum, length of the wire, shape, color, etc., etc.. Now, in order to proceed to a dowsing diagnosis, here is how it must be done, according to Dr. Alfredo Roux of Vichy (France):

1° - It is necessary, first of all, to adjust the length of the pendulum on a healthy part of the patient. To do this, hold with both hands the stick around which the wire is wound (fig. 13) or hold with the right hand the small rod (fig. 14) with the wheel, and give the pendulum itself an oscillatory movement. While the oscillations last, wind or unwind the wire around the stick (or lengthen or shorten it by sliding the wheel) until the pendulum has decidedly changed its movement, turning to the right or to the left according to the polarity of the patient.

2° - Once the apparatus has been set up in the above manner, it is to be run slowly and with a firm but not rigid pulse along the whole of the body of the individual to be examined, beginning at the head and

ending at the feet. Passing over the healthy parts of the sick person, the pendulum will turn in the same direction in which it was turning when we proceeded to its registration, while it will change its movement when it encounters some infirm organ. Instead of making the pendulum walk all over the body of the person whose diagnosis is to be made, it may also be held fixed with the right hand, touching with the left the various parts of the body of the same person, obtaining the same results as with the preceding method. It is evident that with the aforesaid systems we will easily succeed in finding the point where the disease is located, and, if we have some good anatomical knowledge, we will be able to say which is the affected organ; but with this we will certainly not know at once the nature of the disease. Dr. Germain Brochenin, by means of a quadrant (fig. 45) has succeeded in indicating to us directly the groups of diseases corresponding to the different radii of the quadrant. However, I have modified the whole of the picture devised by Dr. Brochenin in this sense: that at each radius prolonged outside the external circumference, instead of writing, grouped, the different diseases, I have substituted numbers for the groups. For example: in the picture in question, to the ray passing through degree 70, Brochenin assigned the following infirmities: soft ulcer, hookworm, sciatic paralysis, neuritis; I indicated this group with number 13 and in the Table relative to the quadrant under this number I catalogued those same infirmities so that the dowsing operator could not know them a priori and let himself be influenced by them. But after, when, that is, he will have seen the pendulum swing on one of the rays of the same quadrant, for example on that one corresponding to 320°, he will look for, in the attached table, the illnesses attributed to that group and he will see that they are: amoebic dysentery, pulmonary emphysema, convulsive cough, etc.. Once he has thus found the group of diseases to which belongs that which is sought for the sick person under examination, he will proceed to the identification, or clarification of this, by writing on as many sheets of paper the different names of the aforementioned diseases (amoebic dysentery, pulmonary emphysema, convulsive cough, etc.) and, passing slowly over them with the pendulum, while with his free hand he touches the sick person or some object belonging to him, he will ask: "Is this the disease of X...?". The pendulum will swing on what will actually be the disease sought. Here

it is useful, however, to give a warning: when the pendulum oscillates on the quadrant, for example on the ray corresponding to 305° , naturally it oscillates also on the ray that is in front of it and that with it forms a diameter: 305° - 125° ! that is, we will have two opposite rays: O - 125° and O - 305° . Which of these two will be the one referring to the disease to be diagnosed? Will it be the Maltese fever corresponding to 125° ? Will it be the blastomycosis corresponding to 305° ? To know it immediately and with absolute certainty it will be sufficient to touch, on a sheet of paper, a line about twenty cm long, divided in the middle by an O and having at one end the number 305 and at the other the number 125. Then the pendulum is suspended on one and the other number. The one on which the apparatus will turn will be precisely the index sought, unless the other half of the diameter is a reflected ray: in which case the results will be equal. Almost all the treatise writers of medical dowsing establish the series of gyrations of the pendulum for every single disease, pretending, in this way, to identify it. But we observe that they do not agree also on the indications of the pendular movements, because there is he to whom the pendulum turns in right direction when it wants to give an affirmative answer; while there is he who obtains the same result with left-handed rotations, or with longitudinal or transversal oscillations. Thus for some the pendulum turns according to the hands of the clock on the healthy organs, and for others it oscillates or remains stationary, to begin to rotate, then, when it coincides with a sick part of the body. The same is true of the series or turns of the apparatus, which reveal the diseases. For example, Brochenin counts, for diabetes mellitus, 20 right-handed rotations, while others count 32, and others 40. Everyone. Because both the movements of the pendulum (rotations or oscillations) and their number are in a close personal relationship with the operator.

And therefore, as I have more times said, it is necessary that the dowser, before dedicating himself to the dowsing practice, knows deeply his possibilities, his power of capture and emanation of the mysterious waves that connect him to the world that surrounds him; it is necessary that he knows with precision which is his polarity, in which way the pendulum answers to his questions, and how many rotations it makes him for the single bodies, for the single illnesses that he wants to study. In compiling the table, however, I have also included the number of rotations and the fundamental radius for each disease, according to Brochenin's indications. The external numbers written on the prolongation of some rays of the quadrant (fig. 45) correspond to the different groups of infirmities listed in the Table. From the long, but not complete, list of the diseases to which men are subject, we see at once what is the Fundamental Ray of each of them. We know that the Fundamental Ray is always the same, it is always immutable for each body and for each disease. But the fundamental rays are sometimes of two or even three species; viz: Principal Fundamental Ray, Secondary or Reflex Fundamental Ray; Tertiary, Weak Fundamental Ray. The secondary F. R. can be considered as a luminous ray reflected by a mirror, and therefore it will always be oriented in the opposite direction to the principal or dominant one. In fact: the reflected ray of the fundamental one oriented NE-40° will be the one oriented SO-220°. This serves us for control, since the pendulum will have to turn equally at 40° as at 220°. I repeat here that while the direction of the R. F. never changes, whatever the operator is, the number of rotations, instead, is personal to the dowser; but it

can be very well that two or more pendulists find the same number of rotations for the same disease. Let us now see how to use Dr. Brochenin's dominant R. F. quadrant. First of all we lay it out on a table, orienting it with the compass on the magnetic axis North-South. Then, in its center, one places the witness or photograph of the person to be diagnosed, interspersing between the dial and the witness or photograph,

a clean sheet of paper, to avoid any possible impregnation of the dial. The pendulum is swung in any direction above the witness. The apparatus, after a few rotations, will infallibly begin to oscillate in the direction of the dominant ray of the principal disease of the infirm. Let us suppose that the pendulum oscillates on a diameter of 200-200°. We find that at 20° correspond four diseases: Malaria quartana, Conjunctivitis primavera, Rubella and Echinococcus cysts. I have already said how to recognize exactly which of these four diseases is the one that has affected the person being examined. It will be found by selection. But this is not enough. The pendulum is to be swung slowly along the circumference of the quadrant and will turn on the radial prolongation that refers to the disease sought. If the patient is present, the whole pendulum will be touched with the left hand while the device will be kept suspended on the centre of the quadrant until it has, with its energetic and precise oscillations, revealed the direction of the R. F. However, as I have said many times, it is not necessary, in any way, the presence of the patient to make a precise diagnosis, which can also be made at a distance with Tele-radiesthesia using, for this, objects belonging to the person to be examined. Of course, such objects must be impregnated with the emanations of the sick person. They can be divided as follows:

(a) Parts of the person: blood, urine, saliva, skin, hair, etc;

b) Objects belonging to the person: handkerchiefs, gloves, pencils, fountain pens, wallets, purses, clothing, etc.;

(c) *Photographs, writings, etc.*

In possession of one of the objects listed above, it is necessary to find the R. F. by making the pendulum travel very slowly around the object placed on a

table from which it is isolated, so as not to feel the effects of any impregnation that may have remained on the table. The radius of the circle that is circumscribed by the pendulum must be proportionate to the mass of the object under examination, and, therefore, if we have a tuft of hair, it is obvious that the circle itself will be restricted; but, equally, at a certain point the pendulum will pick up the R.F. and at that point the apparatus will make that number of turns which corresponds to a given disease. Now, if we can conceive of a diagnosis being made on objects which belonged to the individual with whom we are concerned, because they are, as I have said, impregnated with the emanations of the individual himself, what is more astonishing is to make a precise diagnosis on a photograph, even an old one, or one reproduced by printing. To give a mathematically certain explanation of this strange phenomenon is not yet possible; but to testify the truth of the facts we have before us thousands and thousands of cases checked by illustrious doctors, by scientists, and by an infinity of persons who certainly did not allow themselves to be misled. And well says the now famous Christophe, director of the magazine *La Prospection à distance* (85, Rue des Murlins, in Orléans-Loiret, France): "It is really ridiculous to see people not lacking in intelligence, go to war against facts! The dowsing phenomenon will resist, unshakable, to all the assaults of eloquence of the most official pontiffs. On this point we must not have any fear "for the future".

On a photograph we can know the disease by which the person photographed is affected; not only that, but we can also guess what other diseases he may have had in the past. Thus from the portrait of a deceased person we can also infer from what infirmity he died. If I were to mention all the diagnoses made with complete success by means of Tele-radiesthesia, I would need as many volumes as the *Treccani Encyclopaedia*. Therefore it is not possible, in these few pages, to quote as many examples as the reader will find in the publications I will indicate in the Bibliography.

Another method of diagnosis, according to Bost.

Bost starts from a completely different principle: he searches for diseases by examining the left hand of the patient (figure 46), which he opens with the palm facing upwards, the fingers somewhat detached from each other. To each phalanx of the fingers, alternating in the order I-IV-II-III (excluding the thumb), as well as to each fleshy protuberance of the palm itself, Bost assigns a number corresponding to a part of the human body or to some of its functions:

Brain. Head.

Throat. Larynx.

Arms. Hands - Shoulders.

Celiac plexus - Seni. Assimilation.

Stomach. Diaphragm.

Belly - Intestine.

Kidneys - Spine.

figura 46 (dal Bost)

Sexual parts. Urinary tract.

Thighs - Hips - Anus.

Knees.

Legs - Ankles.

Feet.

Liver - Blood circulation - Digestive system.

Knees - Bones - Teeth - Spleen - Joints - Rheumas.

Heart - Blood - Vitality.

Brain - Arms - Nervous system - Lungs - Bronchi.

External sexual organs - Muscles - Nose - Bile.

Stomach - Chest - Lymphatic system.

Breasts - Throat - Internal sexual organs - Veins.

The organs in italics are those corresponding to some phalanges of the fingers and to the small mounds of the palm: this allows a certain control of a first prospection carried out either on one or the other part of the hand. Now, bearing in mind that the pendulum never works in the same way on a healthy part as on a sick one, it will be necessary, first of all, to record the pendulum on the cable of the hand that is being examined; that is, it will be necessary to find the length of the wire and see how it turns and oscillates. Let us suppose that it turns according to the hands of the clock; we will thus know that the normal state of the individual is represented to us by this rotation and therefore if, starting from the phalanx, we inspect, slowly and orderly, all 19 points indicated in fig. 46, we will find the one or those,

depending on the number of diseases that have affected the person to be examined, in which the pendulum will turn in the opposite direction. If, for example, this contrary motion occurs on 13, we know that the sick person may have disorders of the circulation of the blood, or of the liver, or of the digestive system. Writing on three sheets of paper the names of these three diseases and interrogating them with the pendulum, we will find with certainty the one we are interested in knowing. If the person being studied is a lady, it will be necessary to see how the pendulum behaves on the mount of Jupiter (13) - blood circulation - and on the phalanx (8) of the little finger. If the pendulum does not give any sign, the examination should be postponed for a few days because the woman is evidently in the period of menstruation. On the other hand, if the pendulum stops on the third phalanx of the ring finger (6 or 19) a pregnancy can be presumed. During these experiments the hand being studied should be bare and not have rings. In addition to these methods that I have so summarily illustrated (Bourdoux, Roux, Brochenin and Bost) I could also mention those of the

figura 47 - Quadrante del dr Marty

Bovis, Dr. Leprince, Bosset and many others; but I would go too far from the modest path I want to follow, which must allow me only to reach a well-

defined goal: that is, to inculcate, in my kind readers, some notions of this great art or science, which is called Radiesthesia, and the trust they must put in it. However, before continuing, I want to speak here of an extraordinary means to know the state of health (vitality) of any person, near or far. I have saved this description for last, so much so that the thing seemed to me, ab initio, astounding and so real, positive and prodigious were the results obtained with this system, by myself and some friends, in hundreds of cases that were offered and of which we had precise and truthful answers for 98% of the cases. This method of energicometry (as it might be called) is due especially to Dr. Marty who also designed a disk graduated by 5 in 5 degrees: a kind of protractor (fig. 47) which gives us at once the state of health of a person and, at the same time, tells us whether a medicine is favourable or contrary to the health of the same person. The physical conditions of the individual to be prospected result from the reading made in the upper part of the disc; that is, starting from 180° (West) going to 0°/360° (East). The lower part, on the other hand, indicates the distance, or gap, between the degree of vitality of the person under examination and that of the medicine to be administered, since the greater the gap, the greater the effectiveness of the remedy. To know the above, here is how to proceed. In the centre of the quadrant is placed a photograph or other object of the person whose state of health is to be known, interposing, as usual, a piece of clean paper between the quadrant and the witness, always to eliminate the influence of possible remnants. Then place your left hand on it and with the other suspend, on the center of the disk, your pendulum to which you will give a slight rotating movement. After a few moments you will see it oscillate spontaneously, directing its oscillations automatically towards a point on the upper part of the disk. The higher the graduation indicated by the pendulum, the better will be the health of the subject under examination. Consequently, the more the pendulum will swing to the right, the worse it will be. When the pendulum will mark 0°, we will have the sure, irremediable indication of the death. At 30° we will know that the person, to which the search refers, is very very weak, and that, therefore, his state is rather serious. At 90° health is good and vitality quite remarkable. Above 90° there is exuberance of life. However, in making the above findings must also be taken into account the age of the individual of which the examination is made, because abnormalities are often encountered. Normally you could keep as starting points the following data:

from 180° to 170° we have the maximum vitality, that is, that which is to be attributed to persons who have before them the whole path of life to be accomplished. Such are the children;

from 170° to 140° we find the vitality corresponding to that of youth;

from 140° to 100° we have that of adults; from 100° to 80° that of people from 50 to 60 years old; from 80° to 40° that of people from 60 to 70 years old; from 40° to 10° that of very old people.

But a young person can be affected by a temporary or chronic disease that alters his vitality at the moment in which the dowsing examination is made; and therefore instead of finding with the pendulum, let's suppose 150° , we detect only 70° , 60° or even 40° . Vice versa we can have an old person who, instead of 60° , can reach 90° and even 110° . There is, therefore, nothing absolute and the practical and wise dowser must always keep in mind the different factors that concur to guide the movements of the pendulum. But the wonderful utility of this dial does not stop here. Possessing, as I said, any object of a sick person that is also at your antipodes, you will be able to follow day by day, hour by hour the course of the illness and maybe establish a diagram.

Even the attending physician, being at home, without moving, with only the photograph of his client, can know every minute of the day the conditions in which he is. In any case, knowing the degree of illness of the sick person, the doctor can determine the most suitable medicine, even at a distance. To do this he need only superimpose on the photograph or other evidence of the patient (objects placed in the centre of the Marty dial) the remedy that he would think of administering to him, and then start his pendulum working again until it fixes its oscillations on a given point of the circumference. Let us suppose that the apparatus has given the sick man 30° and the medicine 20° . This must be discarded without fail, because it would be harmful to him, perhaps fatal. If, on the other hand, the medicine should impart to him oscillations directed at 150° , 180° , 200° , we can be sure that the remedy will be favourable to the sick person. And the more favourable it will be to him, the greater will be the difference between the degree marked for the subject and that recorded for the medicine. All that I have said here can also be applied in veterinary medicine to animals. But it is necessary to warn and to keep well in mind a very important fact: not all the operators can have the same identical goniometric indications, because they depend on the greater or lesser sensibility of the dowser, on his physical or moral state, etc., etc.. This proves that there can be no effect of suggestion. But the differences of reading that can be found in this operation of diagnosis, between two or more operators, will be found also in every other their research, reaching, however, always the same definitive results,

because everything is proportional in dowsing. And since I have here spoken of what I would call the harmony between disease and medicine, I will also expound another very rapid and sure way to evaluate it. There are two cases: the patient is present or he is far away. In the first case the dowser places himself in front of the subject to examine, holding in the left hand the medicine, while with the right hand he will suspend the pendulum at about 30 cm from the patient. Better still if he will hold it in correspondence of the infirm organ. If the pendulum remains stationary, it means that the remedy will do neither good nor harm. If it turns according to the spheres of the clock, it will be good. If the pendulum turns to the left, or if it oscillates, the remedy should be discarded. If the subject to be cured is not present, but we have a photograph, a writing or any other object of him, we will put these on a table; we will lean the left hand on it and with the right hand we will operate the pendulum. The results and deductions will be as in the previous case. This method of examination can be done by the dowser on himself and can serve not only for medicines, but also for foods. Indeed for this last investigation the use of the pendulum should be very generalized and diffused because there are so many maniacs who deprive themselves of foods that would perfectly suit them, only because they believe that they are bad for them! With the pendulum, and always with the system described above, everyone can also regulate the dosage of his own rations. To cite an example: I want to know how much pasta I can eat in a day. I sit down in front of a table so that the top of the table is at chest height, then while I keep the pendulum suspended in front of me, I put on the table, slowly and little by little, the uncooked pasta. The pendulum will continue to swing to the right, until the pasta will not exceed the limit allowed to my organism. I have done the test a hundred times and always my device has fixed the daily ration of 150 grams, of which 125 dry for the midday meal and 25 for the evening soup in broth. And I'm doing just fine with that. In order to complete as much as possible this part of my work concerning medical applications, I shall here add a few more instructions which may serve not only for summary diagnoses, but also to enable a reciprocal check to be made between the different methods adopted and between the various results obtained by them.

figura 48 - L'uomo astronomico

The first of these methods is that designated in fig. 48 and which some have called the astronomical man and which we have taken from Glahn, making, however, some changes because it seemed to us that in the original drawing some parts of the body represented did not coincide with the wording written on the circumference. The use of this quadrant is always the one indicated for the previous similar figures: with the right hand the pendulum is held suspended on it and the rotating motion is impressed, while with the left hand the right hand of the subject to be examined is held or, in the absence of these, a photograph, a writing or any object that belonged to him. The pendulum, at a certain point, will change its rotations into oscillations and will indicate the sector of the quadrant that includes the illness of the patient.

If there are no illnesses, the pendulum will remain motionless on the central part of the dial. Vice versa, in the case that the subject is afflicted by two or more illnesses, the operation will be repeated as many times as there are illnesses, stopping each time the pendulum for a few seconds. Preferably keep the dial oriented on the North-South line. Perhaps better than the previous one is the Indicator Dial of Diseases which correspond to as many colours, according to what has been found by N.D. Miss Contessa Bianca Zileri of Vicenza, and which I wanted to represent in fig. 49 in order to follow the same system adopted until now for the graphic pictures, especially since the colours coincide with the various cardinal points. I must admit that this new dial, in many tests I have personally performed, has always corresponded perfectly. It is used as I have already said for the previous one. When in the same sector are included two or more diseases, write them on a sheet of paper, keeping the hand free from the pendulum on the subject or on a witness. The pendulum will turn on the name of the searched disease.

Blood pressure determination

You don't always have the special equipment (sphygmomanometers) and a doctor who can tell you precisely what your blood pressure is, knowledge

of which is always useful and sometimes necessary. Now also here our wonderful pendulum comes to our help, without requiring difficult or complicated operations. So if you, most courteous reader, want to know what your blood pressure is, all you have to do is open your left hand, forming between your thumb and the other fingers a sort of arc of a circle measuring about 6 cm in internal diameter, so that the axis passing through the half circle formed is in a vertical position. Then with your right hand you hold suspended above your hand, but in coincidence with the aforementioned vertical axis, your pendulum at a distance (vertical, of course) of about 1 cm. If the pendulum does not move, let it descend slowly until it starts to turn or to oscillate. When these movements occur count them carefully because each rotation or oscillation represents 10 degrees of pressure. Thus, if you count 17 rotations you will have 170 of pressure; if you count 12, you will have 120 of pressure; but remember that if the pendulum rotates above the hand the pressure will always be high; when it rotates or oscillates in the hollow of the hand, at the height of your middle finger the pressure will be normal; when, finally, the movements of your small apparatus occur lower than your left, the pressure will be low.

figura 50

If, instead of operating on yourself, you operate on another person, have him hold his hand as I have already said, but with your left hand hold the right wrist, or the left, depending on the left or right hand on which you investigate while examining it with the pendulum.

USE OF THE PENDULUM AS A THERMOMETER

This, too, is a fairly easy operation, which has always corresponded to me perfectly in finding the degree of fever of a sick person. I operate as follows: I hold my pendulum suspended on the chest of the subject with my right hand, while I grasp the pulse of the sick person with my left hand and count the number of turns that my instrument makes. Let us suppose that it turns between 38 and 39. In this case I ask, even in a low voice: "does the patient have more than 38°? If the pendulum answers affirmatively with its rotations, I continue to ask: "How much is it? 38 and 1 tenth?... 38 and 2 tenths?" and so on until the pendulum, which will have remained stationary or will have oscillated, begins to rotate. Or I can follow this other system: I make the pendulum turn, while I ask: "38 and 1 tenth?.... 38 and 2?... etc.". The pendulum will stop, as soon as I will have said the degree and the decigrade corresponding to the reality.

PULSE COUNT

Hold the pendulum suspended with the right hand on the wrist of the left hand, so that the latter is turned with the palm up. With the watch, count how many rotations the pendulum makes in a minute. The number of turns will also be the number of pulsations. In the case of operating on another person, hold the pendulum with the right hand, while with the left hand hold the wrist of the subject's right hand. The examination will be carried out on the left wrist of the patient.

EXAMINATION OF A DIABETIC'S URINE

It is well known that one of the phenomena produced by diabetes mellitus is that the diabetic secretes, together with the urine, a more or less large quantity of glucose. Now it is very important for the patient to know precisely what percentage of sugar he secretes in his urine. There are chemical preparations that give the precise percentage quite quickly. However, a certain knowledge of chemistry is required, equipment is

needed, expensive reagents are needed, etc., etc., etc. But with the pendulum you can obtain the same results without any expense. Here's how to proceed: collect in a container half a liter or rather a liter of the urine taken from the urine released in 24 hours, and at a distance of about 30 cm from the container, pour slowly, grain by grain, in a bowl or on a saucer, powdered sugar, while holding suspended, at medium distance, the pendulum that will continue to turn to the right until the amount of sugar poured into the bowl will be equal to that contained in the urine that is analyzed. When these two quantities are identical, the pendulum will immediately change its movement and will begin to oscillate. Thus, if the sample of urine is 500 cc and if the sugar poured into the beaker weighs 8 grams, we will know that we have 16 per thousand of sugar in the urine itself. But the important thing is not only to know this percentage, but also to take into account the amount of urine that the diabetic secretes in 24 hours. Since we suppose that Titius will urinate 2 liters per day with 16 per thousand of glucose, he will excrete from his body a total of 32 grams of sugar in 24 hours, while Caius who urinates more abundantly, let's say 4 liters per day, but with a percentage of 6 per thousand, will excrete only 24 grams of glucose per day.

A very quick way to know if a person is suffering from diabetes, or not, is to hold in front of him, at a distance of about 30 centimeters, some sugar or other substance rich in glucose, at the height of the chest and to suspend with the right hand the pendulum between the chest of the person under examination and the sugary substance. If the pendulum turns, there is no danger of diabetes because the rotary motion of the pendulum tells us that the substance is suitable for the person being examined. But if the small apparatus oscillates between this and that, we must assume that there is the possibility that the individual is diabetic, or has a tendency to this infirmity or, at least, that the sugar is not favourable to him.

DETERMINING THE SEX OF AN UNBORN CHILD

This important quasi-divinatory problem has always fascinated and still fascinates not only dowzers, but also gynaecologists, doctors and many other people who would like to know the future sex of the creature still enclosed in the maternal breast. The denigrators of dowsing say: "How come you, that you exclude from the wonderful virtues of the pendulum, the one to guess the future, how come you want to pretend that your device can reveal you the sex of an unborn child, that is to predict the future? This question, which would like to demolish the pendulum and the dowsing, is simply idle because we do not predict the future at all, with our pendulum, but we simply note a real state of fact because in the womb of the pregnant woman, the creature, even embryonic, already has its physical sex well defined. And I say physical sex to distinguish it from what could be called spiritual sex. In fact there are quite frequent cases in which the spirit, the soul of a person does not correspond in any way to the external sexual characteristics of the same person. Thus there are individuals who, although they have masculine characteristics, possess perfectly feminine manners, tastes and feelings, while there are those who outwardly have all the masculine characteristics and yet contain an absolutely virile soul; I cite a famous historical example: that of Joan of Arc. But let's leave it at that because we would be entering another field quite different from ours, and return to the subject at hand. I was saying, then, that by examining a pregnant woman to know, before birth, what will be the sex of the unborn child, we do nothing more than a simple statement of an already existing fact. Indeed, we should not even say: "what is the sex of the unborn child", but we should instead say: "what is the sex", because it is already established in the womb of the future mother. The difficulty, however, lies in the research, in this kind of diagnosis. The oft-quoted G. Brochenin, in his interesting *Traité de Radiesthésie*, at p. 99, states that out of 29 cases examined by him (of which 25 on photographs) he has accurately guessed 24. Various are the methods for such prospecting. Here are some which I take from the Manual of René Lacroix-à-l'Henri:

1° - Having as witnesses a young man and a young woman, the operator observes if the rotations obtained with the pendulum (while he touches with his free hand the future mother) are always

harmonized with the young woman who serves as witness. If the rotations are harmonized, the fetus will almost certainly be female. If, on the other hand, there is discordance of rotations, we will call the male witness and, with the index finger of the left hand placed 10 cm from the abdomen of the pregnant woman, we will see if there is harmony with the aforementioned witness. If so, we can assume that the unborn child will be a male.

2° - Take a magnet or a compass and determine which of them is the North and South poles. Keeping the left hand lightly resting on the belly of the woman being examined, the pendulum is made to turn successively on the North and South points of the magnet or of the compass needle. If the pendulum turns on the North pole, the fetus will be male; if it turns on the South pole, it will be a female.

3° - Georges Discry in his treatise of Dowsing (*La Science des Sourciers à la portée de tous*) simplifies even more the system. First of all he establishes well, with several tests, the polarity of the mother because (as I said in the first pages of this study) the woman, like the man, can have a positive or a negative polarity. Once this polarity is well defined, the operator places the future mother so that she is oriented North-South, with her back to the North. Then he places himself in front of her with his left hand outstretched towards her, keeping the pendulum suspended with his right hand. And he expects it to turn or, however, to move. If it turns, the unborn child will almost certainly be a boy. If the pendulum swings, it will be a girl. But let us suppose that we are faced with a polygynous pregnancy. How to operate? After having taken the polarity of the mother, the pendulum will give us first that of the strongest unborn child; then it will stop and, after a few seconds of rest, it will give us the polarity of the second; and, after another stop, it will show us that of the third.

However, since you may prospect the pregnant woman on a day when she is not in good health condition (this would invalidate your diagnosis), you will have to start your prospecting again after some time. Such research should never be done before the seventh completed month of pregnancy.

According to some authoritative authors and dowzers, studies on the sex of the unborn child can also be carried out on a photograph of the mother.

EDIBLE MUSHROOMS AND POISONOUS MUSHROOMS

I speak of this subject in the present chapter because it seems to me that it re-enters a little in the medical field to which I have mentioned as briefly as possible, just to give a vague idea of the immense resources that the pendulum and the Radiesthesia offer to us, referring the reader who would want to better educate himself in the matter, to the beautiful works that I quote in the Bibliography. The distinction of the good mushrooms from the bad ones, made with the pendulum, does not present great difficulties, because the apparatus will always turn in negative sense (left-handed) or will oscillate, on the poisonous mushrooms, while it will turn in positive sense on the edible ones. But if we want to have a control, we shall take one of them of which we know with absolute precision the edibility and we shall place it on a table on the left of the operator. Then, one by one, the mushrooms to be examined will be placed at a distance of about 30 cm from the aforesaid table, keeping the pendulum suspended between the two. The pendulum will turn to the right when the mushroom under examination is edible, and will swing or turn to the left when a poisonous one comes under it. As the means which I propose is very simple, and requires no expense, I see no reason why the test should not be attempted. I do not say that, on the basis of a first experiment made by a person still inexperienced, we should accept and eat with our eyes closed mushrooms of unknown origin and uncertain nature. God forbid! I confine myself to giving this advice: take a certain number of edible and poisonous mushrooms that you know perfectly well, and make on them the tests that I have suggested to you. You will then see whether or not the method indicated to you corresponds to the truth. The whole of Radiesthesia, the divine science among all, is in fact based upon those mysterious waves which envelop us

on every side, and which, starting from us, spread through the infinity of the universe, constituting one of the many gifts which the Creator places at our disposal for the good of Humanity.

Part Seven

Other useful applications of dowsing

If I were to enumerate and describe them all, it would require a volume of a much larger size than this modest paper, which limits itself, as I have repeatedly said, to giving a brief idea of this new Science and to enticing scholars to devote a little of their time and ingenuity to it. However, before writing the word End, I still want to mention some other resources of the wonderful pendulum, for objects that interest our daily life, all made of struggle and work.

SEARCH FOR WATER OR GAS LEAKS FROM UNDERGROUND PIPES

You have to know, before anything else, what material is the pipe that you want to search. Let us suppose that it is made of cast iron and is used for the conduct of gases. As a witness, take a piece of cast iron in your left hand and search the ground for the location of the pipe. Once it has been found, follow it slowly, always holding the piece of cast iron in one hand and the pendulum in the other, which will continue to rotate until the operator finds himself on the vertical point where there is a gas leak. At this point the pendulum will abruptly change its movement. The same can be done to search for a water leak, whatever the tubular material; cast iron, iron, lead, cement, eternit, etc., as long as one takes care to always hold in the free hand a sample of the material with which the piping is constructed.

SEARCH FOR TREASURE HIDDEN IN A WALL

Stretch a copper wire horizontally against the wall at a height of about 1 metre from the ground and, touching it with the fingertips of your left hand, walk slowly along the wall, keeping suspended, with your right hand, the pendulum that will not give any sign until it coincides with the point where

the treasure is found, or on the vertical of the same point. Then detach the wire and, from the horizontal position, place it in the vertical position passing through the aforesaid point. And, as you did before, do the same now, following the wire with one hand and holding the pendulum with the other, but starting from the floor and going up to the ceiling. There will be 3 cases:

1° - that the new point indicated by the pendulum corresponds to the one previously found;

2° - that it is either above or below the said point;

3° - that the pendulum does not give any sign for the entire length of the vertical line: this means that the treasure will be found on the same vertical, but in the foundations of the wall. It must be remembered, however, that treasures hidden in the intersections of walls are very difficult to find because their radiations are not graspable: this explains the reason why in ancient times they were hidden precisely in those positions of the buildings.

If, instead of being inside a house, the treasure is outside, lay the copper wire on the ground after having attached one of its ends to the foot of the wall of the aforementioned house and at right angles to it. Follow the wire with the pendulum in your hand. If it does not rotate in any way, move the wire in the same direction, i.e. parallel to the first arrangement and begin the pendular test again. Retry the test always moving the wire until the pendulum starts to turn. At that point you will find what you are looking for.

SEARCH FOR NECROPOLIS OR ANCIENT HUMAN SKELETONS

The operation is more or less the same as in the search for water or gas leaks in pipes; but instead of taking a piece of metal as a witness, a piece of bone is held in the hand that holds the pendulum, while with the other hand, stretched out in the guise of an antenna, the operator, turning on himself, will identify the direction of the tomb. Walking in that direction, he will end up at the point where there is the skeleton or necropolis sought. If he also wishes to know the position of the head and feet of the skeleton, he will have to draw, even sketchily, on a sheet of paper, the figure of a man, and placing the forefinger of his left hand on the head drawn, he will observe when the pendulum starts to rotate, because the point of the ground on which the device will turn will be precisely that in which the head, or rather the skull, of the skeleton is located.

QUANTITATIVE ANALYSIS OF A COMPOUND BODY

I have already said how to dose the quantity of water with which the innkeeper or the milkman have decided to baptize their goods. In the same way we can find the composition of any substance or body that we are interested in knowing. Suppose we want to know how much copper there is in a duralumin fusion. First of all we will weigh accurately the melt itself: let it be 3,500 kg. Holding the pendulum suspended above it, we place at the usual distance of 20-30 cm many pieces of copper until the pendulum starts to turn from a standstill. We weigh the copper placed on the table and find, for example, that it weighs 140 grams. Establishing the proportion:

$3500 : 140 = 100 : X$ we will see that copper is in the percentage of 4%.

In this way any compound can be quantitatively analyzed, provided that the bodies used as samples are available.

IDENTIFICATION OF COUNTERFEIT COINS

This is also a very useful and secure application for instant verification of coins, whatever metal they are. But since those most commonly counterfeited are those of silver, let's take them as an example. At a distance of 20 cm place on a table a coin that we know to be good and one on which we have doubts. On the half of the distance that separates them, that is to say at 10 cm from one and the other, we suspend the pendulum. If the pendulum turns in the positive direction, i.e. to the right, the suspect coin will be good, if, however, the device does not turn, or if it oscillates, we will know from this that it is false.

CAR ENGINE FAILURE SEARCH

No matter how well you know your car engine, it sometimes happens that you cannot immediately identify the fault that suddenly prevents it from working properly. Is it the magnet? Is it the spark plugs? Is it the carburetor? The valves...etc. etc. Well, do this: with the right hand hold the pendulum on the engine and let it rotate. Then with the other hand touch successively the single parts of the engine which, during this examination, must be necessarily still. When your left hand touches the faulty organ, the pendulum will immediately stop its rotation. If, on the other hand, you have a precise drawing of the motor (plan or longitudinal section) you will obtain the same results, and perhaps with greater precision.

VERIFICATION OF ARITHMETIC OPERATIONS

For a long time I have used the pendulum for many professional purposes and I have never had any complaints. The most elementary of these applications are those which serve me for the verification of the four arithmetic operations, for the extraction of the square root, etc.. Thus, if you make two multiplications with the same factors, one right and the other

wrong, you will see that the pendulum will turn rightward on the first and will swing on the second. Don't say that it is autosuggestion because you can do the experiment with your eyes closed, or on two separate sheets of paper that you will place with the pendulum holding the written part against the table, so that you will not see which is the wrong operation and which is the right one.

VERIFICATIONS OF CHEMICAL FORMULAS

The results are the same as for arithmetic operations. In fact, write on two identical tickets any formula: for example that of copper sulfate. On one of the cards write the right one: Cu SO_4 and on the other one, write the wrong one $\text{CU}_2 \text{ SO}_6$. You will see that on that one the pendulum will turn positively: on this one it will oscillate.

CALCULATION OF REINFORCED CONCRETE

Sections of the beams, columns, etc.. Having first established the lengths and then the loads that must be borne by these structures, we proceed by questions and write on a sheet of paper, well spaced, the numbers that represent the square centimeters of the sections; for example: 600 - 700 - 800 - 900, etc. etc., and we hold the pendulum suspended for a few moments on each of them, asking: "Is this section okay? Thus we arrive at the number we are looking for. Let us suppose that it is 1500. Knowing what ratio, more or less, must exist between the height and the width of the parallelepiped that is called a beam, we will owe to that one 50 cm and to this one 30 cm. Identical operation is done to know the total section of the irons that will constitute the reinforcement of the beam. Let's assume that the pendulum gives us 12.60 cm. Searching in the tables that are found in many technical manuals we will find that to the aforesaid section correspond 4 irons 020.

SEARCH FOR THE NEUTRAL AXIS OF A BEAM

All engineers know how important it is to know the precise point at which the neutral axis of a beam is located, i.e. that longitudinal strip of the beam which is not subject to any stress. In order to find it quickly (and the calculations made by talented colleagues have always given me confirmation), I draw in large scale 1: 10 a stretch of the beam in question in longitudinal section, and I draw a straight line orthogonal to the axis of the solid. Then while with the right hand I make to slide slowly the point of the pendulum along the aforesaid orthogonal line, keeping it distant from it of a few centimeters, I follow the pendulum with the thin point of the pencil. At a certain moment the pendulum starts to turn vigorously. In the point in which this turning happens, it passes surely the neutral axis searched. Always proceeding in the manner indicated for the search for the sections of beams or round bars for reinforced concrete, we will also find the thickness of pipes or containers intended to contain liquid or gaseous fluids even at very high pressures.

ERRORS OF HARMONY

Often, when writing music, the accidents (sharps, bemolli and bequadri) that are really true accidents, escape the composer. Other times a misinterpreted chord is written in one way rather than the other and those blessed errors of musical grammar are committed that make the pedantic worshippers of Madama Armonia wrinkle their noses. Damn! Here there is a C sharp instead of a D flat! Phonetically the two notes are identical; so much so that on the piano they are represented by a single key. But from a strictly harmonic point of view there is a difference, because the C sharp can be the sensitive of the natural D and therefore it tends to rise and settle on the D, while the D flat tends to descend on the natural C. This is of course when they are not so-called passing notes. This is not enough: with the pendulum we can find not only an error in a chord, but also in a succession of chords, as - to cite an example - in the following resolution in which the error consists in the parallel motion of the two extreme notes, B and C, as we can see under letter A, while it should have been written as

under letter B. You will ask me how I operate to perform these verifications. It is all a matter of patience.

I begin by examining the first page of music with the pendulum, wondering if there are any errors on that page. If the pendulum oscillates, I move on to the second page because I know that on the first page there are no errors. If even on the second page my device oscillates, I move on to the third, the fourth, etc., until the pendulum, with its rotary motion, warns me that there is something wrong. Then I present the pendulum in front of one of the ends of each line of the page. At one of these extremities, the pendulum starts to turn: therefore the mistake must be on that staff and therefore scrolling slowly, I end up finding the chord or even the note that is wrong. With a little practice the operation of revision can be accomplished quickly enough; in any case it is much less tiring than that carried out at a desk or even at the piano, especially if this revision is performed by the author of the music who, having already imprinted it in his brain, can play it all, from top to bottom, overlooking the mistakes made without even finding them again.

PSYCHOLOGICAL SURVEYS

We know that by means of the pendulum we can direct our Fundamental Ray where we wish, and thus connect our vibrations with those emanating from other brains as well as from other bodies. From this fact springs a very important consequence for us: that of penetrating, almost, into the mind and soul of other people and of knowing their real feelings. Every person, by necessity, is obliged to have relations, more or less close, with his fellows but, especially in business relations, these are often superficial. We make

acquaintances, we talk, we deal with very different subjects, whether as professionals, as employers, as workers, as industrialists, as merchants, etc., but very rarely do we take care to know with whom we are really dealing and too often we forget the wise warning contained in the well-known proverb: "clothes do not make the man". And so it often happens that we experience strong disillusionment, bitter illusions and that, perhaps, we fall into some trap. Well, even in this case, our powerful pendulum can be of great help. How? you may ask. Here it is: when you have to start a practice, any kind of negotiation with a person that you do not know well (or for a long time) try to have an object that belonged to him: a photograph, a writing, a pencil, etc. Then, when you are alone, write down the questions that you want an answer to on many pieces of paper. For example, "Mr. X... is he honest? Can he be trusted? Will he cause me any trouble? Any pain? Is the deal he proposes good?" and so on. Then put on each of those sheets of paper (one at a time) the object coming from the individual on whom you want to make your investigation and place your left hand on it while with the right hand you hold suspended the pendulum which will answer yes with the rotary motion to the right, and no, with the oscillations or with the rotation to the left. To complete the foregoing I will indicate a very simple but infallible means of knowing whether two persons have mutual and sincere sympathy, whether there is, in a word, communion of soul between them; it is sufficient that they write their signatures on two pieces of paper and that these two pieces of paper be placed on a table, close enough together. If the pendulum swings in the direction of the centre line between the two pieces of paper, there is no sympathy between the two signers; if, on the contrary, the pendulum swings round, and almost embraces the two writings, you may be sure that there is a mutual esteem and a great affinity of feeling between the two writers. I believe that of all the immense services that the pendulum can render us, this one of the psychological examination, which I will call psychological, is perhaps among the greatest and most useful, because each one can, in this way, know inter et in cute and infallibly what another thinks of him. How many businessmen, and especially those in high positions, who have legions of people around them who compliment and flatter them, should have recourse to the modest pendulum which will always answer with the utmost sincerity. And then how many disappointments many would experience! How many incredible truths they would discover! I say this especially for those in the political

world who live in the highest echelons and who, although they always live in an atmosphere of distrust and in fear of being deceived or betrayed, often extend their hand with all confidence to those who have the dagger ready to strike them, while they turn their backs on those who, for their own good, would like to give them good advice and useful warnings. If I were asked the reason of the different behaviours of the pendulum, I would answer that it is to be found in the irradiations transmitted by the witness we have used, who still retained the impregnation of the emanations emitted by the person we have dealt with. I could continue at length the list of dowsing applications in every field of human activity; but it seems to me that what I have so far exposed is enough to give an idea of the importance that this new science will acquire with time. As I have already said one of the most useful services that the pendulum can render us is to know the qualities and the defects of the people with whom we have more or less intimate relationships, because so we know better how to regulate our relationships. Parents, in the first place, governesses and teachers should make use of it in order to know the aptitudes of the children who, by heavenly will, have been entrusted to their care. And therefore we have tried to collect all the necessary elements in the quadrant of fig. 51. On examining my quadrant the reader may object to my enumerating the same item twice. For example, I mention among the aptitudes of the spirit that for medicine, and in sector V I place the profession of a doctor. But this shows that a man may have the aptitude to be a doctor, without having succeeded in becoming one; while it may well be that he has obtained such a degree although he has aptitudes for, say, music or agriculture, or for some other branch of knowledge. The quadrant, therefore, serves to establish, in persons, not only their polarity, but also their profession or the trade they exercise, as well as their qualities, their passions, their defects, and so on. The examination can be made either with the presence of the individual whom you want to study, or, as usual, with some witness of his. The operations of research must be repeated according to the answers one wishes to have. One will begin with the mental examination (sector I); then one will pass to that of the soul (sector II), and afterwards to that of the spiritual polarity, etc., etc.

QUADRANTE PER LE RICERCHE D'INDOLE
PSICOLOGICA E PRIVATA (ideato dall'ing. P. Zampa)

figura 51

1° The intellectual degree, in No. I; 2° The virtues or qualities of the soul, in No. II; 3° The aptitudes or polarities of the spirit; a) for the arts; in No. III; b) for science, in No. IV; 4° The profession exercised, in No. V; 5° The trade practised, in No. VI; 6° The vices and passions, in No. VII; 7° The bad feelings, in No. VIII.

Conclusion

I do not know what impressions the benevolent reader, who will have had the good fortune to follow me so far, may have received from the reading of these pages. But I would hope, if he has not been completely persuaded by the facts and theories I have endeavoured to set forth as clearly as possible, that a certain feeling of curiosity or doubt has penetrated into his soul. This doubt and this curiosity will lead him, I am convinced, to make some trials, to take an interest in the matter, to study it, at first as a joke and as a pastime, later with deep interest and with profound passion. And then I will have obtained my aim, I will have reached my goal. If he proceeds cautiously but tirelessly along these new paths that I have indicated to him, if he scrutinizes with intelligence and intensity of thought the new vast horizons that I have made him glimpse, he will be able to solve many problems that seemed insoluble, many mysteries that seemed impenetrable. And yet, however victoriously, yet laboriously and sometimes painfully, man may travel the arduous path that crosses the boundless fields of human knowledge, however much he may make a new discovery every day, and every day tear a new strip of the great veil that hides from us the mysteries that Mother Nature encloses in her bosom, we will have to increasingly realize our weakness and our smallness before the mysteries of infinity and eternity. We will have to humbly bow our forehead surrounded by pride, we will have to extinguish the flame of vanity that burns in our soul. And, in the pious and sweet resignation of our impotence, looking up, to the great Light that warms, enlivens and illuminates everything, to the One who in Himself sums up Space, Time, Science and Goodness, we will have to recognize that there is only one Source of true knowledge from which we can draw the drops that it gives us at the price of our work, our efforts and our sacrifices and that this Source has only one name: God!
