STUDY OF SHAPES AND CONCEPT OF

FIELD OF COHERENCE

Presentation for beginners

INTRODUCTION

This course is written for the first time. It has been dispensed many times since the 1975s. This is a simplified presentation that serves as a starter for those who are interested in what relates to forms and what we have been developing for a number of years and which we call *Coherence Fields*. The theoretical developments will not be discussed here. You will have to report for acquaint yourself with the works of Jacques Ravatin "Theory of the fields of coherence" ¹ and of Jacques Ravatin and Anne-Marie Branca "Theory of Forms and Fields of Coherence", work in the process of being finished. This allows you to enter completely in this new theory which contains a model of thought.

Many congresses have been organized by the ARK'ALL group. The last was held at Camac in July 1996. It was organized by Anne-Marie Branca and Bernard Menguy, this one architect in Camac is member of association ARKOLOGIE whose creators are Serge and Françoise Hennemann, both architects. These persons can be contacted for any construction of housing as well as Luc Labat and Sophie Nouvel from Barka.

Chapter I

The Forms Seen by the Ancients and the Moderns

Shapes are linked to marks or are marks themselves.

The benchmark, for this study, is fundamental. It allows the observer to describe what surrounds it. He projects his landmarks into the infinitely large or the infinitely small. He describes himself itself by landmarks.

The coordinate system can be a system of axes from an origin and a unit of measurement; he can be of a comparative order: better than, more beautiful than... It can even correspond to a vague nature which will make it possible to give a more precise description. He can be linked to the notion of belonging: to "contained in...".

This landmark is important because we are going to postulate "existence without landmarks".

Thus, in human life, concepts are used where there is no measurement, no of landmarks. Also we find the following concepts: love, kindness, unbearable pain both physical and moral, etc.

This existence without markers will be called " *the Global* ", the existence with markers being " *the Local* ".

There will only be a *Global* while we can find " *Local* ". The world described by rational thought is a particular ' *Local* ', but other ' *Locals* ' are possible.

Travelers have sometimes described it. Our society refuses these contributions that it cannot assimilate.

All this enters into the "Coherence Field Theory²".

We will not say that the concepts of love, fear, intense pain, state of well-being... are in the *Global* because it would then have a notion of belonging, therefore a setting up of benchmarks, but rather linked to the *Global*. "To be bound" in the language of forms as we developing it in no way involves the concept of landmarks.

² See the works of Vladimir Rosgnilk, Jacques Ravatin and AM Branca

The form is for us more or less locatable - It can be in the *Local* by example the usual local, that is to say as it was presented to us, imposed It may be only partially in the *room*, "another part" of this form being linked to the *global* - here we must be careful because the expression "another part" involves a delimitation, therefore a location; it should then be known that this expression is not adequate, but we can use it without fear of errors because we will see that to test a form it is necessary to have a correct representation of it. The representation, that is to say everything that we arrange as knowledge, point of view on the arrangement concepts and concepts themselves, is fundamental.

We can ask ourselves the question, from the moment the form is more or less present or more or less absent in the space-time structure [E - T], i.e. is also fundamental than this structure, which we can still express by saying that the form emerges or submerges in the ET structure: how did the Ancients see shapes ? - the Ancients being the Greeks, Egyptians, Hebrews, Sumerians, Chinese there is 6000 years old, or even Toltecs, Aztecs, Mayas, Incas... finally the Pre-Columbians, or still the Eskimos, the Aborigines of Australia, etc... They perhaps did not see them not like the modern man, that of the civilization in which we are and that we will name "Rational Civilization" or "Rational Field of Coherence".

For example, were the Egyptian pyramids - Cheops - seen 3500 years ago like now ? It seems that denial is the answer to this question!

The new concepts developed by the ARK'ALL group, then the association DECALUM and the company EUREK'ALL® as well as the association ARKOLOGIE are in this way. We must not delude ourselves about the concept of progress often used in our society, this progress brought about by the superiority of the present over the past in point of view of knowledge, technology, attitude, etc... This is not how he reason because past civilizations were probably quite different from this that rational thought can describe about them. To absorb certain areas, it requires adequate thinking and not wallowing in "the rational thinking that can be allow us to approach any field".

So looking at bas-reliefs on walls and monuments and describing them is simply force them into the Field of Rational Coherence (C. de C.

for Field of Coherence) when they are not adapted to it - the rational C. of C. does not deform them as one deforms a hat that one wants to fit into a box too small for him. One can simply hope, in the case of the hat, that after taking it out of the box, it will return to its original shape. While the bas-reliefs are totally deformed if one is not aware of the existence of another thought than the C. of C. usual (rational). This other thought is called “ *Other Coherence Field* ” or “ *Dynamic Coherence Field* ”. In the other C. de C., the stockings, reliefs, ancient monuments, ancient languages, ancient history and legends, go convey their true meaning.

We can ask ourselves the question :

By postulating the existence of the Other C. of C., by constructing it little by little, is that enough to be sure that we catch up with the thought of the Ancients, or the Thoughts of the Ancients? He seems that the answer is positive when we discover the operability of certain forms found or made! But it must still be taken into account that these forms will being in the rational representation of the ET, all this constitutes a representation, which is certainly not those of the Ancients. So we can cause transfers between the form of the present and the more or less distant past.

Thought does this well: it can create the concept that allows access from a knowledge to another unrelated to the first. It is therefore the “Transfer”.

The world is a creation of the brain; at the same time as the brain imagines, the observer is immersed, diluted in its construction. The process is not rational³ — even for the construction of the rational C. of C..

The transfer makes it possible to pass from the usual C. of C. to the other C. of C., forms like ancient alphabets help facilitate access to this knowledge, this sensation, this understanding; moreover, there are multiple forms that allow this passage.

For the Ancients, the forms were fundamental whereas in our world modern, they are consequences, functionalities for the realization of Objects Techniques (OT) except when facing Aesthetic Objects (EO) [4] and [14], [2], [3] and [15].

³ See the works of Vladimir Rosgnilk, Jacques Ravatin and AM Branca

The Phenist Objects (OP) are made from delocalized functionalities. They correspond to most of the objects made by the Ancients.

Partially localized shapes can be used as landmarks. Every living thing is a form partially localized, and even very little localized. Any description entails the presence of a landmark? One can always imagine an abstract space with which is associated a form. This abstract space is attached to the usual C. of C. by our presence in this C. de C.. The observer puts as many landmarks as possible, but some of these may vanish with the necessities linked to the form, they are fugitive.

What is very important is the concept of "necessity" [1], [2], [3], [4], [15].

It will not be developed in this first year course, like many others. concepts elsewhere.

But, as Léon Delpech wrote in the preface to [1], this approach which gradually emerges in this course "is not a game of thought nor an attitude of group wanting to stand out or isolate itself, nor sterile complications... this is a constructive step in understanding and a new awareness.

Nor is it a result of the crisis of rationalism, a vain escape, but much more the beginning of an emergence in human thought, an emergence which contains the thought of the Ancients... Researchers whose work has remained unknown out of intolerance on the part of rationalists or the fact that the technological society does not could support their contributions, these being awkward for its stability, are highlighted in these courses. So there is JW Keely, N. Tesla, TH Moray, E. Hendershot, L. and MT Sprink, Coutelen, F. Dufourg, L. Rota, S. Bignand, G. Calligaris, G. Bergé, G. Lakhovsky, Enel, Prioré, A. Béchamp, L. Boutard, A. Morichini, D. Ghadiali, F. Crombette, W. Reich, H. Mayer, Geitel et Wilson, l'Abbé Fortin, Laithwait, H. Krayner, A. Schmidt, Mathias, T. Brown and many more... »

**Creation is an ideal mirror
that the Spirit presents itself to itself
so that her beauty appears to her freely
and as if from outside.**

Chapter II

Forms ÿ Footprints ÿ Relocation

I. Introduction

We cannot find an exhaustive classification of forms - despite this we develop here a particular type of form called form-imprints. There are 3 of them which are fundamentals.

The first 2, which will be presented here, make it possible to establish the so-called Eifs at the level E-F-F.

II. Heuristic presentation

It was discovered by researchers Enel (Prince Skariatine) around the 1920s, then continued by Chaumery, Bélizal, Lafforest, La Foye, then by Ravatin, Pagot, ..., from kinds of emissions related to colors, shapes.

These are not electromagnetic waves as researchers initially believed.

Here we come across existence without landmarks, these "waves of form" like Enel named around the 1920s are linked to the *Global*. We are therefore not faced with a phenomenon linked to a rational process but to entry into an immense domain that is existence without landmarks.

A completely delocalized form emits a lot of these "emissions" that we called "EIFS4 " for each.

You can also find these kinds of eifs ... which are not related to the form but to the mass⁵. They are called EIMS. We will not study them in this course. One can move from eifs to eims and vice versa.

One can still wonder whether there are such entities which are linked both to the shape and mass. This only finds mixtures of eifs and eims.

4 EIF: E for emergence, I for influence, F for form, plural Eifs

5 This was established by Pierre de Montgrand

We will therefore consider the first 2 forms-imprints⁶. They will be placed vertically. They make it possible to detect the eifs discovered by Enel called "eifs des colors" or by abbreviation "colors" because they were discovered from blue, green, yellow, red rags... Other "colors" had to be added, which are not not, such as white, black, infra-red, ultra-violet. We therefore speak of the spectrum of "colors".

We have tried to construct this spectrum of "colors" differently, so as to justify this supplement which is not, if not inspired by the electromagnetic spectrum, in the part visible from this spectrum.

This is where the first two form-imprints come in.

III. Forms-imprints and eifs

We must remember that what is detected in this area is not there, in our usual field of coherence, since

it is related to the *Global* ; on the other hand, the effects are certain places. We can say that the AND structure serves as support. But will it still serve as support for another reality that does not concern her? It may not! At that moment (if one can say), we will have phenomena which cannot no cases to be detected, which would have an existence linked to the *Global* and perhaps even to something other than we will not develop here [15]. Human being will then have to imagine another medium than the AND structure and, if no support is present, the human being will have to transform to conceive new concepts that will give him access to this replacement media or equivalents.

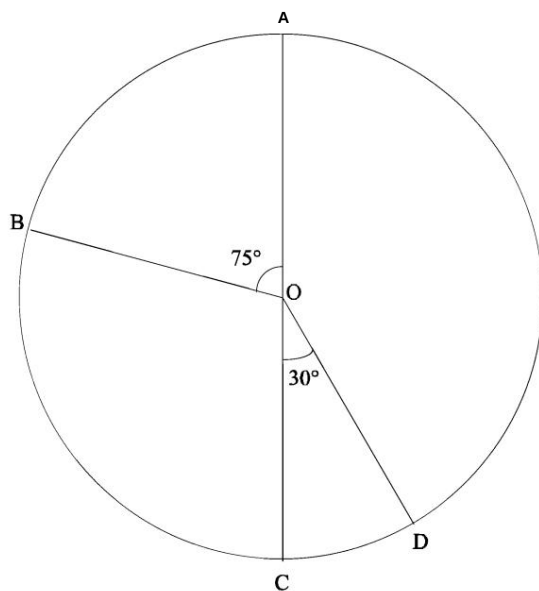

Figure 1

Let's see the first imprinted shape: on

consider a circle with center O and radius OA. On this circle, let's place the points B, C, D such that $AOB = 75^\circ$; C is diametrically opposed to A; $DOC = 30^\circ$. One can

⁶ We gave them this name because they appear like footprints in a plan.

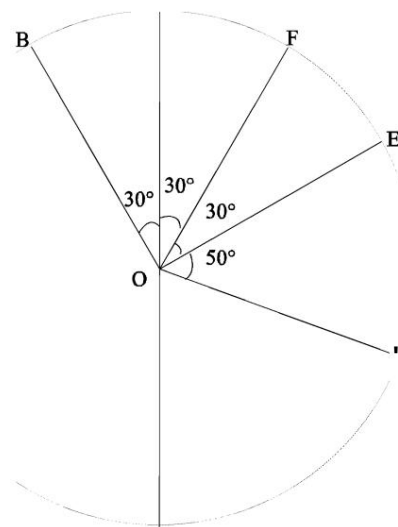

Figure 2

extend OC outside the circle. The form thus described without the circle is called form imprint of the first species (figure 1).

Consider a circle with center O and radius O.A. Points B, C, D, E, F are on the circle.

such that $AOB = FOA = EOF = 30^\circ$ (Figure 2)

"D $DOE = 50^\circ$

C is diametrically opposed to A

We can extend OC outside the circle.

Such is the form-imprint of the 21st species.

These two forms (of the 1st and 21st species)

can be placed in

vertical planes, point A will then be considered the highest and AC is perpendicular to the horizontal plane.

We will use them like this.

Consider a semicircle and a diameter MN in a plane horizontal. Let K such that $MKN = 40^\circ$ and trace KM and KN. Let us plant in K the imprinted form of the first kind, vertically. It is in the vertical plane of trace OK on the plane horizontal (see figure 4).

This gives the eifs (figure 6).

But we can keep only the horizontal plane shape and plant in K, the shape imprint of the second kind, vertically, entirely in the same plane as previously, of KO trace (see FIG. 5).

We detect a new eif vertically to A, O, C that we write V and the previous V will be written V+ (the V' is also detected vertically from A, O, C).

We thus arrive at 8 eifs. These are the "colors".

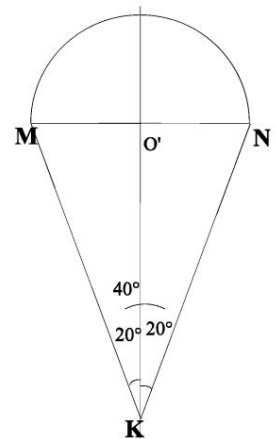

Figure 3

Figure 4

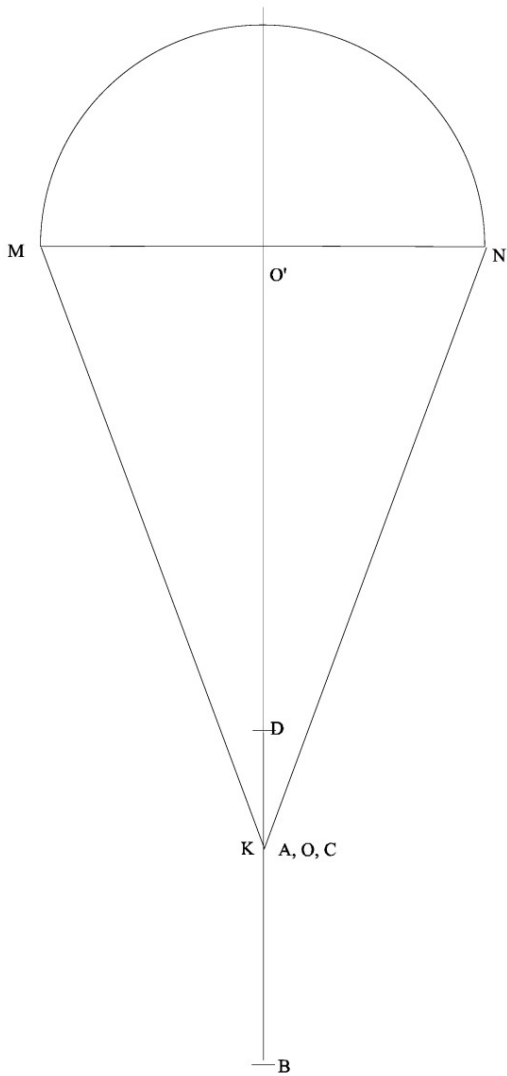

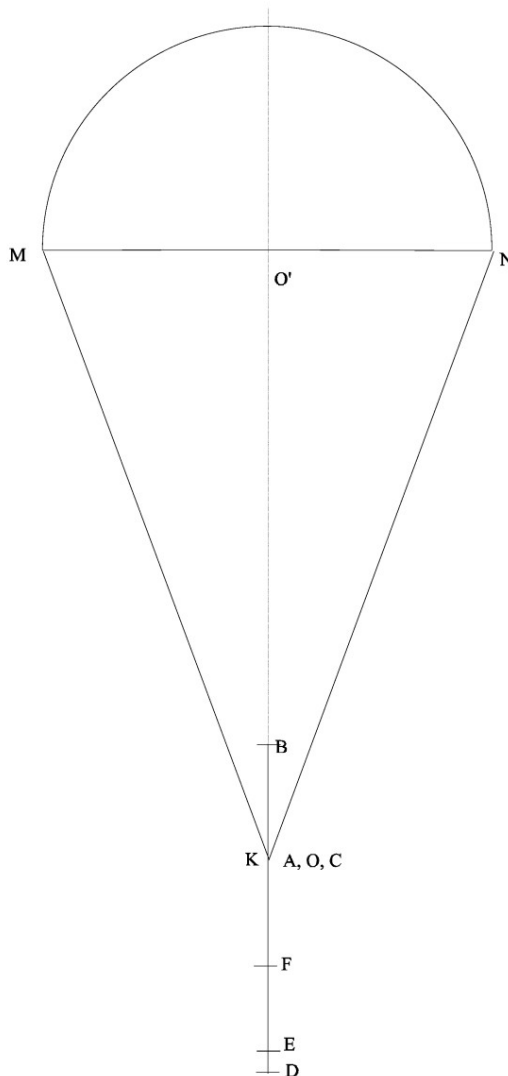

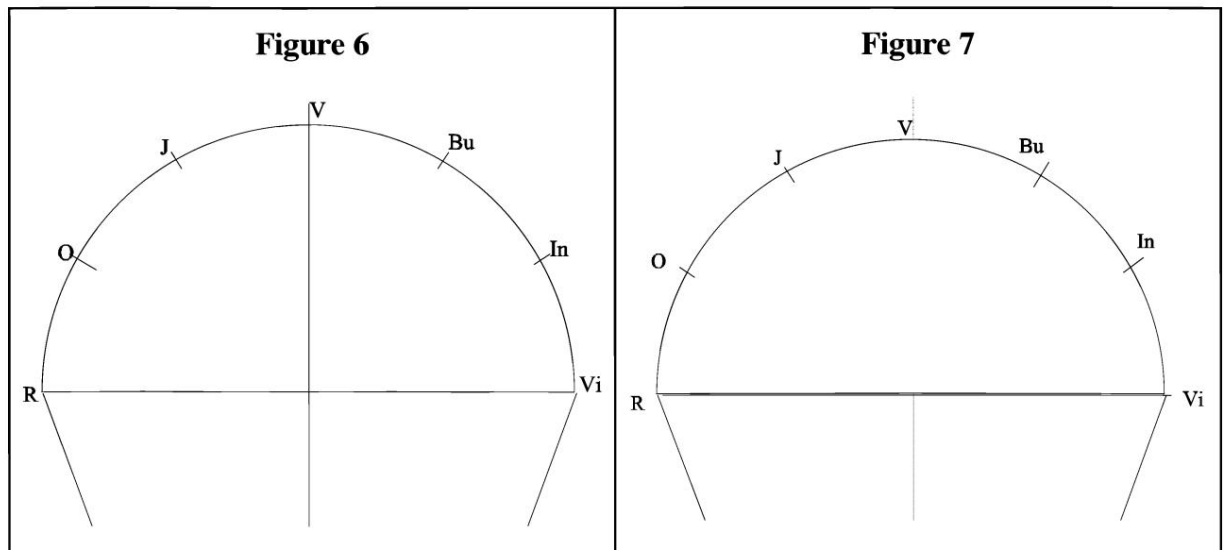

Figure 5

Reminder: in the works of Enel the "colors" were placed on a circle and green to which it corresponds the $V+$, was diametrically opposed an eif which was written v .

This is the one we found in this montage. Thanks to this new eif we are going to bring up new ones listed by Enel, Chaumery, Bélizal, Lafforest, La Foye: IR, BC, N, UVi. These no longer correspond to colors but in this spectrum they keep this denomination.

We will keep it.

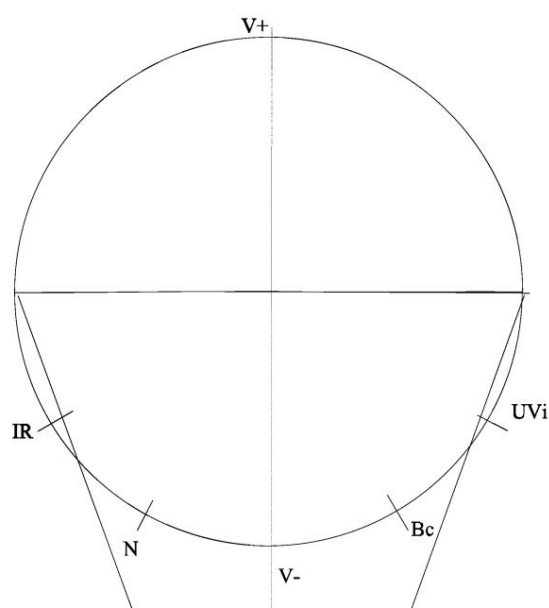

Figure 8

To make these 4 news appear, you must return to the figure above, still in a horizontal plane: we draw the circle full. We send in K some V . We detect the 7 eifs previously found, the V diametrically opposed to $V+$, as well as IR, BC, N, UVi.

In summary: we found 12 eifs.

$V+$, J, O, R, IR, N, V, Bc, UVi, In, Bu

Exercises

- 1) Build these forms imprinted with *lier* and 2nd kind.
- 2) Detect so-called undifferentiated spectrum eifs; of course it's not about determine the eif specified by its name, this will be seen later. We will search only eifs.

IV. Supplement to Chapter II

Detection of eifs

These eifs must be detected.

They are not electromagnetic waves as some have believed; they thought that they were located in the electromagnetic spectrum, i.e. below the hard y-rays, or beyond the Hertzian waves. Below the ys are the hard ys and beyond the hertzian waves, ultra-hertzian waves.

There have been multiple approaches to this field; we thought in the way of Enel and those who more or less followed him: Chaumeray, Bélizal, Chaisemartin, Lafforest, La Foye, Pagot, Philippe, and even the ARK'ALL researchers and those following them of ARKOLOGY, of BARKA; Morel's way was slightly different on what happened detects on the forms, then there was that of Béasse and still many others like that of the Servranx brothers.

We realize that the form is not apprehended in the same way by everyone and that if we are not attached to a school, we will describe a form by its "emissions" of ways very diverse.

So, we can say that by this remark, we are not facing waves electromagnetic; ditto for sound waves or more generally of any type where

We have therefore entered a domain where we no longer measure and yet there is existence.

It is the existence without landmarks, linked to the *Global*.

The eifs are linked to the *Global*.

To detect them, you will need:

either measure the phenomena linked to the *Local*, they are because part integral part of our rational world, the usual local.

- or use mancies.

Why the mazes? ! : they seem as old as the world.

Pendulum, wand, stone throwing, flight of birds, interpretation of signs etc...

function in the sense that they give information because the observer forces himself to redo his cerebral gait.

The human brain works in wandering and is faced with the unexpected: by this process he "discovers". That is to say, he extirpates from himself what is potentially existing. The human being, the observer⁷, is not only what one thinks in the usual C. of C., but it is largely undetectable and so it is that the mancia takes its value.

A few tips

In research by mancies, phenomena are triggered - which vary according to the people - and allow to work, in some cases without tools - rod, pendulum, etc... -. Extra-sensory means are placed which are smells, tastes in the mouth, sensation of wet feet from the passage of water currents, sensations indefinable on certain parts of the body and even painful sensations sometimes, a muscle reflex.

The practice of the pendulum is called pallomancy. This term has been forgotten for dowsing which is there to remind us that we are linked to phenomena close to radiation, whereas it is not that at all.

Rhabdomancy is clairvoyance using the wand. It is assumed, by analogy with the rational view, that between two points, if information from one is found in the other, we detect something in between. Thus, in the field which we concerns, statements such as: "objects radiate", "emit", "this place is charged", are frequent assertions without any basis.

⁷ In the works of Vladimir Rosgnilk, then of Jacques Ravatin then in the work to be published by J. Ravatin and AM Branca "Theory of Forms and Fields of Coherence", the word observer is replaced by that of obs which is more general than that of observer as we discover it in physics.

These ideas have only served to establish pseudo-theories and directed experiments which limit themselves by the principle mentioned⁸.

In our society, we know the effect of inert objects like the refrigerator which emits infra-red radiation, an X-ray TV on the sides. They create an influence around them often from a great distance.

But we must not impose electromagnetic radiation wherever there is affecting. This radiation is perfectly described by Maxwell's equations.

On the subject of objects, forms, effects are actually felt, are perceived by sensitive people - fortunately there are still some in the rational world - from the object, or even far from the object, without any connection between the object and a place, or another form.

It should be noted that the volume of influence has nothing to do with that of the object, sometimes it seems to be related to its mass but there, again, the exceptions are numerous.

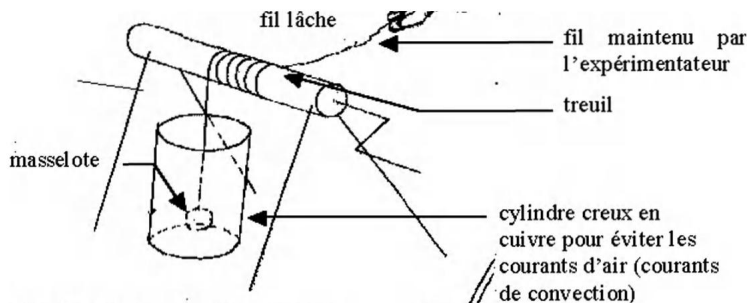

Let's see the example of the empty glass, placed on a table without a drawer, alone on the table and center if the foot is not central. A special eif is detected in the axis of symmetry of the glass above the table and above, but it can happen that the eif (which, as we will see further is a V'E) is detected in the horizontal plane of the table surface.

Naturally, only an investigation by mancy or direct clairvoyance will confirm this.

The rationalists sought to explain the dowsing act by excitation of the brain in connection with these famous radiations from where nervous control leading to a reflex muscular determining the gyration of the pendulum or the rotation of the rod.

Experiments show that it is quite different.

Baron de Reichenbach who lived in his castle in Germany until the 1865 had set up, among other things, the following experiment:

~~le tout pose sur une table.~~ After a while the pendulum moves. It must be understood that the technical object

pendulum - thread with weight at the end - is no longer quite that; we'll say that he has partially relocated, which means that the criteria that establish the physics usually are no longer quite valid.

The same goes for the baguette: even with little practice, you realize that the movement of the stick is not due to a muscular reflex directed in the direction of a rotation. The wand rotates 100 to 180° while the clenched hands oppose the movement, to such an extent that the rod breaks under these conditions. We can make a fork with dry grass, bend it in a V. Being very flexible, it does not does not turn but bends downwards, movement impossible by muscular action of the hands. We can also take 2 springs linked at one end and held at the other, placed in a V, point down. This V, too heavy and too soft, must be held vertically. When we passes, with a mental convention on an underground stream, the V-point goes forwards or backwards which is impossible to achieve by muscular action

If the stick rises, he comes to the idea of bringing in a vertical force which acts to bottom up on the stick. But in the course of its movement, this instrument is no longer a technical object; one cannot reason about it as one does for the objects described in the rational world. Gravity no longer seems to act in the same way in the case of levitations of objects or human beings. Indeed other characteristics appear on these objects and human beings which show that their relocation is accentuated. Measurement processes hardly work anymore. And want them

imposing is not enough to observe the phenomenon correctly; it can disturb the unfolding story.

About the levitations of objects and human beings, it happens much more frequently than it is known, the RBB¹⁰ not wanting facts to come interfere with the few postulates they learned at school, postulates which serve them to hum a partial knowledge, which they want total.

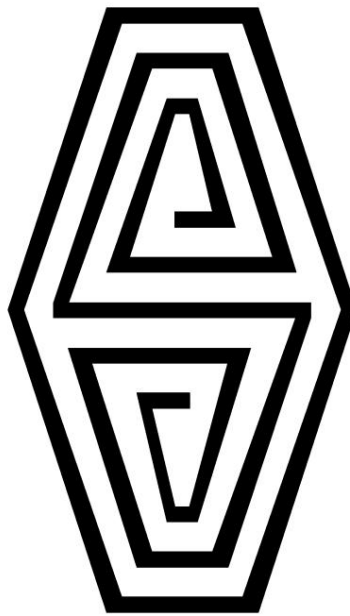

When one writes partial knowledge it is naturally about a knowledge from rational thought which for them is the one and only form of thought adequate to approach the world. They don't understand that thought creates the world and therefore, depending on the chosen coherence field, the constructed world will be different.

9 Yves Rocard, in his book "Le signal du Sourcier" attempted to prove, with supporting experiments, a completely rational explanation of the pendulum effect. There he describes experiments proving the action of a weak magnetic field on muscular reflexes. He absolutely did not believe in the possibility of working from a plan; yet it works very well; then the explanations of this little book collapse. Moreover in this book it is denied the possibility of detecting still water because water must move in the earth's magnetic field. But we must congratulate Y. Rocard for having had the courage to discuss this subject in the scientific entourage that was his. Besides, this book is not for everyone!

10 RBB: Stupid and Stupid Rationalist. Not all rationalists are RBBs, but in our time many of them have become. And this in the name of Science that they invoke as a fearful little boy wants to scare by calling his big brother to the rescue.

Chapter III

Eifs at EFF level

I. Rules of caution

The eifs which have just been presented are said by J. de La Foÿe to constitute the spectrum undifferentiated.

They will be detected by a mancia:

- pendulum,
- rod made of various materials, however they must be flexible.
- Lecher antenna.

You can also use direct clairvoyance, without an instrument. It is the method most quick.

It remains that whatever the method chosen to detect, it is very necessary to pose the question to avoid any ambiguity. Don't forget the representation chosen by the observer. Excellent researchers disagree on what seems the same test because they do not have the same concepts in mind or the same arrangement of these concepts, neither the same meaning associated with these concepts, nor the same stories attached to these concepts, which goes into what is called the tacit knowledge.

It is necessary to get into the habit, in this domain, of probing one's tacit knowledge. this should moreover be done in the rational domain; it would bring a lot of researchers to ask themselves questions about the basic postulates of the scientific world.

You have to learn to detect these eifs.

We will start to simply detect an eif on a set of eifs without trying to bring them back to this spectrum.

For this we use flat shapes or volumes. Care must be taken when using flat shapes, for example drawn on a sheet of paper,

so that the sheet has no lines,

to the leaf's position relative to the viewer, which places the shape.

The observer must become aware that he imposes by habit, his knowledge tacit, an orientation: we say the top of the sheet, the bottom of the sheet...

This is in reality, what we will see later, what J. de La Foÿe called the "North of form".

Some shapes are sensitive to an orientation, to a neighborhood, the neighborhood can even extend to positions of satellites (Moon), planets, sun, constellations. We know the effects of the Moon on the growth of plants: we can put this on the cause of some eifs if the chosen representation wants this not to be justifiable only by eifs, we will therefore find a justification by the eifs linked to the phases of the moon.

A model based on such a representation is not rich enough. It's necessary then think about what the Moon is,
what it means.

We can imagine it as a satellite with its movement around the earth, that is to say, starting from a usual, rational representation, in which we add our light and eifs which are absolutely not elements of rational thought.

We can imagine it as a shape that could even be considered flat, moving against the dark background of the sky, like a window in the sky, with eifs associated - the questions of gravitation absolutely not intervening except for the vertical of the place in a pinch - the Ancients must have used such a representation.

It can be associated with an entity that will come into existence because other entities are attached to it. other stars. These entities belong to the kingdom of the living. It is the set of associated entities which makes each have an existence. To a set of shapes we do match a set of entities. These entities interact with each other and also with forms. Animists follow this path.

A question then arises: which representations will choose the cultures subjected to the light of the moon, or even more, to the presence of the moon?

The observer will therefore choose his model in a representation and will thus explain the effect of the moon on plants. We are not going to talk about an explanation truer than another but richer explanations than others.

In the Dordogne, 35,000 years ago, human beings living in these regions had other representations that were operational in their time; they may not be not anymore.

Planar shapes

Back to planar shapes; they are more delicate to handle than the shapes in volume because they are involved in more diverse representations than the others shapes, for example icons.

There is a cerebral path to take to approach an icon, unless you understand what what is the icon. If this path is not respected, the icon will remain a shape in a flat surface that can be tested for its colors and associated eifs. We see that even if someone is knowledgeable about this unorthodox field, his ignorance of many concepts that do not belong to the usual C. de C. will make it unable to test the icon correctly -We are naturally talking about the real icons. Icons modern or copies of icons absolutely do not have these properties -. We will be able to work on flat shapes to practice. But you have to be very careful about this. that we will seek: for example if we place 3 points in a plane and that we seek the eifs then coming out of the plane, it will not be necessary to represent a triangle if they are not aligned, a line if they are aligned.

Remember that when we speak of eif at a given place, especially of a given form, it is an excess of language, the eif not being identifiable. Simply the effects are detected in this location.

Volume forms

It will be advantageous to start training on shapes with cylindrical symmetry: spool, drinking glass, carafe without handle or spout, vase, etc... The shape is placed on a table without drawers, cleared of all objects. Avoid a table with a central leg and place the shape to be studied in the center.

Then we will move on to shapes: cubic, spherical, etc... then to shapeless and then to systems of forms. By varying the layout of each room in the system one arrives at enormous possibilities.

Experiments carried out in parapsychology, the domain of forms, healings incomprehensible, and much else, tend to set up a world that is not not at all the one described by the C. de C. rational.

Unfortunately, people contrive to return to this C. de C. which is not adequate for understanding of these phenomena.

So it is with dowsing.

It is used in a binary way - especially when the one who practices it is at his beginnings -.

That is, the pendulum oscillates or rotates¹.

We have one and only one answer to a clear question. There should be no ambiguity in the question, no hesitation in the expression of its formulation. For example, we will not say not "is he okay?" », but « he goes! and the answer will be yes or no.

In the "does" an indeterminacy exists that can be found in the answer.

So we throw the pendulum swinging, we ask the question. If the answer is no, it will continue to oscillate; if the answer is yes, it will turn one way or the other.

The direction of rotation may be levorotatory or dextrorotatory. This makes it possible to further impose a condition. We leave it to the reader to find his own.

We know the effectiveness of analytical science with respect to all that is artificial. since precisely most of the constructions made by man come under this analysis concept.

We like to have systems like technical objects: a motor runs or does not turn. If it does not turn, for example for that of an automobile, it is

¹ We will not consider the case where we place the pendulum at rest and wait for it to move. It is often long and certain external conditions can be troublesome.

there is no more fuel or there is a fault. Troubleshooting
orients itself.

A gear turns in one direction or the other, etc.

They are binary systems. Not all are binary. But Cartesian reasoning
removes the ambiguity. Life does not correspond to Cartesian systems. The
usual Coherence Field models that want this are seriously mistaken.

Imbue your model with what was inspired to set up all the tools,
it is to pollute Life.

III. Exercises

Planar shapes

- A circle is traced on a flat white sheet without pointing to its centre. We detect
in the center of the eifs.
- Likewise a square, likewise a regular convex or star polygon.

To think that we have tacitly oriented the sheet by its position with the top and the bottom, which
orients the drawn shapes.

Volume shapes

- We take a glass with cylindrical symmetry that we place on a table that does not have
of drawer. It is not placed above a leg of the table.
- Check that an eif is detected on the lens axis, above and below the table.
- Sometimes we detect one in the plane of the table, check it.

Advice :

1. This axis or this plane can extend over a few decimeters or meters, without
can know a priori. Only a mantic detection will tell.

There will be cases where on the axis above a certain distance no one detects
nothing. It is necessary to check always further on this axis; we can detect again
further away.

2. In dowsing it is necessary to be passive, or better, available, to let come the answer.

You have to be as if you had all the libraries in the world in your head and you lets himself search for the book, the page, the paragraph where the answer is found. We is confident.

However, there comes an answer that seems wrong. You must not admit defeat. he can be a good answer but that the question was badly asked or comes from of the tangle of concrete situations that our lack of experience does not let no one suspect.

Exercise: we practice looking for objects.

For that I take 5 envelopes and I put a postage stamp in one of the envelopes.

Find the stamp?

1. Mix 5 envelopes.
2. Take a pendulum or a rod to find the stamp: don't forget not mental conventions.

I throw the pendulum in oscillation in a plane.

When the answer is positive, it will start rotating (regardless of the direction of rotation).

Corrected:

ÿ we find the stamp.

ÿ the stamp cannot be found - it is possible that the correct envelope is overlooked, the one that encloses the timbre, but that one does not pass above the timbre -.

So we modify the question: find the envelope that contains the stamp.

When we have found it, we will begin a similar experiment. We see that there is a succession to respect.

ÿ Do not forget that we hid, we intended to hide. This, in the test, can interfere with the onset of a positive response. Beware of games.

ÿ If you don't like the game, don't provoke the game.

So do not have an approximate, poorly formulated question.

We call back because it's important: "Do not say, do you?" In this expression there is already has an indeterminacy that can be found linked to the answer and it will then be indefinite, which will lead to discouragement.

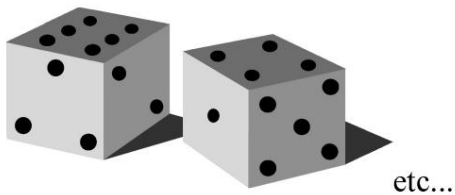

Be wary of the advice of other people, even other dowzers, it depends of their culture, of what they represent. For example in front of "613" an operator will say "digit", or "digits" or number. In fact it is a number composed of figures. Then there is the tacit knowledge already mentioned. 613 for a Kabbalah enthusiast will bring to mind the 613 commandments in the background.

Then notions, although precise, are used inappropriately in the everyday language ; for example pressure, force, tension are used one after the other. place of others.

In this area that we are dealing with, it is not because the benchmarks are variable, that we have existence without landmarks, that we must speak of vagueness and drown in vagueness. It's necessary on the contrary a very great rigor.

Then if a detection exercise is repeated too often, for a beginner, it can come up with errors.

Exercise: we throw a dice under a handkerchief, the figures that come out are

1) look for what comes out?

advice

- If you find the correct result, don't say to yourself: I had a chance in 6 of finding the results.
- If we start again not to tell ourselves it is the 5 that came out, there is little chance that this or again the 5. We fall back into a rational approach and the dowsing is not not.
- A person says to the operator "I challenge you to find such an object" That make ?

Advice :

• don't take up the challenge.

• any failure or semi-success is immediately held against the operator.

We have N possibilities in front of an action; what about the test on the N possibilities?

Advice: be careful because it may happen that the positive answer is not within the N possibilities, and then if we have the preconceived idea that this is in the set of N possibilities, we will find one for sure.

We must therefore think carefully about what we have present in its representation when we start testing.

2) The operator is presented with 6 eggs, one of which is in plaster, and is asked the sex of the unborn chicks. What to do ?

Tip: do nothing because the problem is skewed. We can very well pass on the egg in plaster and give the sex of a chick since we adopt the story of the one who has chose the eggs.

IV. Differentiated and undifferentiated spectra

Another spectrum has been discovered: the differentiated spectrum.

The eifs of the undifferentiated spectrum are not at all those of the differentiated spectrum. If we look carefully, we realize that Enel had already spoken of the differentiated spectrum without name it 2.

Differentiated and undifferentiated spectrum eifs have been used to heal.

We will see the implementation of these spectra in the next chapters as well as the complementary to these spectra of eifs.

The differentiated spectrum was discovered by Enel then taken up by J. de la Foÿe, R. de Lafforest, Chaumerey, Belizal. However, the first presentation, that of Enel, did not not been completely followed by those who were inspired by it.

2 Colonel de Rochas, deputy director of the Ecole Polytechnique until 1905 had discovered 2 "rays", one red and one blue. He could restore certain dysfunctions of the human body by playing on one or the other. Enel knew C. de Rochas personally and worked under his direction until 1904

Chapter IV

The Eifs y Full Spectra

i. The complement of the undifferentiated spectrum

We have seen that the eifs are distributed over a circle that can be opened and extended according to a line segment; Which give :

V+ J O R IR N V Bc UVi In Bu V+
yy

Between two "colors", for example O and R, are all the points of !, interval

O A. The segment is divided into 12 parts of equal length.

The presence of the 12 colors makes it possible to associate new eifs with each of these points.

We will say that the model of the undifferentiated spectrum has an extension. It was employed by Jean de la Loÿe.

Thus we will detect:

- or colors that appear as lines on the diagram: eg. J, V,

This.

r ALREADY R IR NV Bc UVi In Bu V+
yyyyyy

- or lines that are inside an interval: eg. that of the O! R

those I I dars

víyyyyy^ I

AWAY

- or bands: eg. NOT V i.e. in this case we detect at A

and B and everything in the interval AB

The entire spectrum will be called the undifferentiated continuous spectrum.

II. The tree trunk

Suppose we are testing the trunk of an almost cylindrical tree. Let R be the radius of this trunk. The trunk is vertical; by thought one cuts through a horizontal plane.

On the trunk, in this plane, we can detect the 12 colors and the whole spectrum undifferentiated.

But Jean de la Foÿe found on a concentric circle, of radius $2R$, something else.

These are new eifs.

These eifs had been discovered by Enel. He had attempted a rapprochement with the magnetism (M) and electricity (E). So there were eifs of type M and eifs of type

AND.

He had split the undifferentiated color spectrum into 2 spectra, one M-type and the other the type E.

Thus we found:

V γ J O R IR NV - Be UVi Vi In Bu V γ

M-type

V γ J O R IR NV - Be UVi Vi In Bu V γ

the type E

for example we will have Bum, Rm, V+m, V m

and there will be Bue , Re, V+e, V e

This means that we have 2 spectra and the whole will be called a differentiated spectrum.

Jean de la Foÿe had supposed that any color of the undifferentiated spectrum was composed

2 colors of the differentiated spectrum of the same name but type M and type E; by

example :

- Bu would be composed of Bum, Bue
- V+ would be composed of V+m, V+e
- V would be composed of V'm, V'e etc...

3 Nothing will be found on circles of radius $3R$, $4R$ etc... nor on intermediate circles.

That's a bit of a strong assumption. If we have this idea a priori, by testing for lack of skill, we will indeed find confirmation of this hypothesis.

Tip: If you use a mancy to find an answer to a question, it means we don't have that answer. But we shouldn't have a small idea of it, otherwise the result will be directed and therefore the answer will be false. This is the great difficulty, we must let the answer come.

Little by little we will pass to mental conventions associated with abstract ideas but beginning, it is necessary to ask clear questions which will allow quick and unequivocal.

Exercise 1: Either to find a cure for a sick person. We have the list of remedies of a given range or the witness box.

- 1) In mancy we will use the pendulum. What do we do ?
- 2) We throw the pendulum in oscillation, what do we think?
- 3) We move on to the second remedy, the pendulum begins to swing, what do we think?
- 4) For 4 remedies, it is the same, should we deduce that the 4 remedies are good ?
- 5) What conclusion should be given to such a test?

Solution: see end of chapter.

Remarks :

- 1) Avoid starting the dowsing operation with the pendulum stopped.
- 2) By excess of honesty certain beginners try hard, especially vis-a-vis the RBB, to keep the pendulum still for fear of being accused of being responsible for the movement.

This attitude makes no sense because:

- fatigue causes the operator to move the pendulum; it starts with small movements.
- wanting to maintain the immobility of the pendulum leads to keeping it motionless so no response.

- Baron de Reichenbach in the 21st half of the 19th century made

an experiment which tends to show that the motionless pendulum takes a movement after a more or less long time when it is linked to an observer. This experience will not be described here but it is found reported in Fascicle 1.

- 3) It is necessary that, in the case of the pendulum, the hand and the wrist are free and flexible.
- 4) The pendulum should be kept short, so responses are quicker.
- 5) Authors and not the least have associated specific lengths with the wire of the pendulum and even on the wire placed knots affirming that these correspond to specific conditions. It is not so. It holds simply to mental conventions that have not been seen as such by their creators.
- 6) The weight of the pendulum: 8 g. at 70g.
- 7) The rod can advantageously replace the pendulum on the outside when it there is wind.
- 8) About the wand the simplest method is perhaps this one:

By mental convention, it is assumed that the rod dives when the tip of the foot crosses a desired limit, for example, a trickle of water underground. We can then slide the foot on the ground to refine.

But it is necessary to reflect well on this: everything depends on the representation that one is made of groundwater: if it flows in a rocky corridor or in a pipe, we will have lines on the surface which will be clear. Otherwise there may be muddy or sandy parts close to the trickle of water, filled with water resulting in a line that is not very net.

Exercise 2: We are looking for groundwater for a borehole.

- 1) What is the first question to ask?
- 2) Flow
- 3) Composition

Solution to exercise 1 and advice: The search for water is by far the most best known in rural areas. Medical dowsing today represents the field the most worked by amateurs.

Point of view training family } is daily
 agricultural veterinary

Thus economy and health balance are always welcome.

Classical knowledge in human or veterinary medicine is not to be rejected but not always necessary which often surprises the people of medicine because we do not will not diagnose symptoms or illnesses but diagnoses of therapies.

Solution of exercise 2:

- 1) Look for the line vertically where there is a flow of water.
See if moisture zone without flow.
- 2) Ask the question m³/s or l/s in order to find the approximate value. Then
after asking the question: between 1 and 2, 2 and 3 etc...
- 3) Mineral salts in significant quantities? Other impurities. Is the water
drinkable ?

The attitude to adopt is that of the homeopath, that is to say, one seeks the remedy. We therefore often works on homeopathic remedies.

Do not dwell on people who claim not to have restorative effects with homeopathy. Their attitude blocks the possible effect. We find this in the case of the use of a mangle about which some say: "With me it does not not working ! ! ". In this case there it is necessary to leave aside the one who says that because.

indeed, it will "never work with him" since he does not want it walk.

As some say "You can't work on a map because you won't detect anything on the piece of paper constituting the map". From the moment when for them they have decided that, posed that, they will find nothing. They impose the answer before waiting for the response, they distort the research process by command. The order is therefore not for them.

Coming back to exercise 1, we must get out of the habit of thinking "diseases".

What interests us is to find the remedy that the patient needs.

Thus one will seek with the pendulum, with the rod, or an antenna, which remedy one will have need.

In homeopathy: we seek, in front of the patient, the remedy, then its dilution.

If several remedies are found, it is necessary to check if all of them are acceptable and then dilutions of each.

III. Additions to Chapter IV

In the field of forms often intervenes the orientation, this one is sometimes in the tacit knowledge of the individual, by habit and training.

We have seen this previously in the case of the orientation of the sheet of paper, placed on a table. The top corresponds to a tacitly implemented north. This north will end up more precisely in what follows.

Jean de la Foÿe had discovered this particular orientation to which are attached many shapes. It is - he had named it thus - the north of form (NF).

Form North is 6° west of Magnetic North (NM) which is being approximately 5° West of True North, places Form North at 1 lo west of True North.

When Jean de la Foÿe spoke of certain eifs associated with certain forms, these forms - he did not specify - were oriented to NF.

It is necessary to be very careful when carrying out work on the forms to determine the NF and this for each assembly, each experience. Indeed, the NF changes according to the neighborhood.

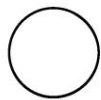

In a cave, it happened to be found at 90° west of the NM, in other cases at about ten degrees east of the NM.

And in the case of the sheet lying on a table, tacit knowledge put it on top following the expression. The high and the low determine the NF.

We can impose this NF. It was Jean de la Foÿe who also found the solution.

We place 2 circles, one black, one white and we put the shape F between the two. the black circle imposes the NF. The centers of the two circles set up the axis N.F.-S.F..

This will be used in particular for the detection of the vital field which we will see further away.

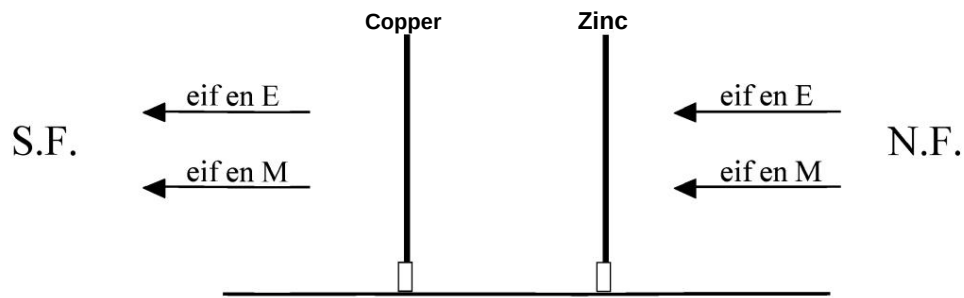

Already Enel had pointed out - still in analogy with the electric current - that the conductive bodies and insulators had different properties with respect to certain eif. That was what had led him to the differentiated spectrum.

An eif of character M was, it seems, stopped by a magnetic body (iron, steel).

An E-character eif was stopped by an electrical insulator (bakelite, rubber).

Then Jean de la Foÿe had prepared the following assembly: he took 2 plates of the same form, one in zinc, the other in copper - these are metals, therefore conductive bodies electricity -.

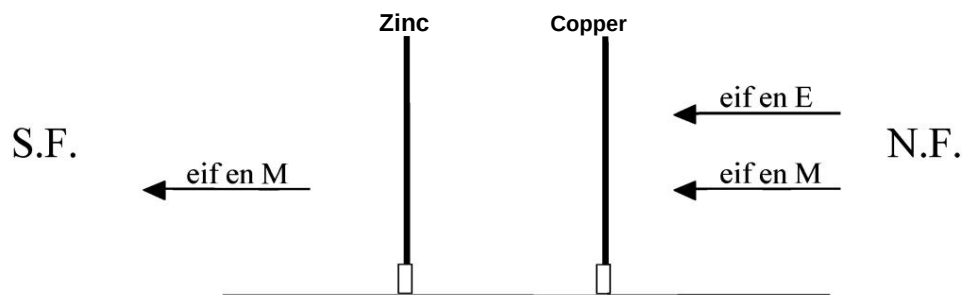

He placed them vertically:

Montage 1

The axis of the system is the NF-SF.

We send according to the 11th assembly an eif in E and an eif in M, we detect after the copper an eif in E and an eif in M.

Montage 2

In this assembly, the copper and zinc plates are swapped.

We only detect F eif in M.

In reality we still detect F eif at E but much further than the plate of zinc.

This experience has only historical value, it will be considered as an exercise.

What you have to see from this is the process of the mind. The underlying idea is the spectrum electromagnetic. This domain of manics and forms is strongly influenced by analogies since it is the operator who sets up the representations. If some of these representations contain analogies or are directed by analogies,

answers that seem correct appear. The operator does not realize that he
a chooses a model that is too poor.

Nor should we systematically reject all analogies.

This is where all the subtlety comes in, which makes for success.

Exercise 1: The material to be used is made up of cylindrical glasses; it is good to
expect five.

We work on a table, in the center - the table must not have a central leg -.

We place a glass in the center of the table, the vertical axis

X

There is an eif on the x'x axis above the table
and below.

Detect it - Here we do not have to specify the eif -.

What happens if we fill the glass at least
half a liquid? - water, oil -

The shape placed on the table is a glass. One can
replace with a silver beaker,
cylindrical.

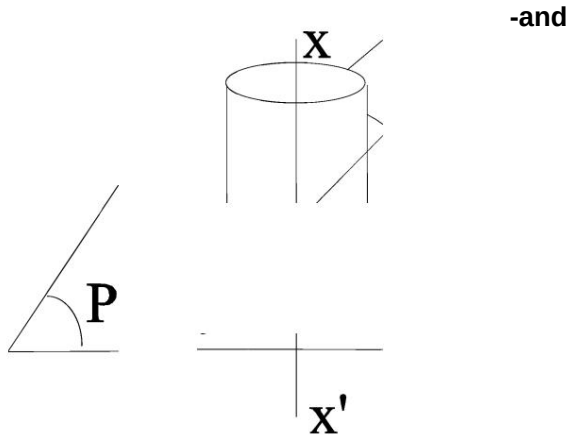

What do we notice?

Place the glass horizontally, locating yourself in relation to the North-Magnetic axis
South-Magnetic.

What do we notice?

New assembly

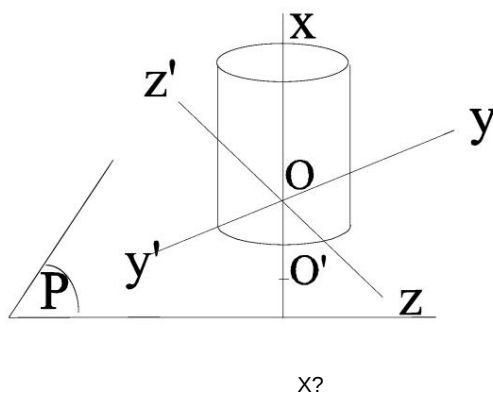

-and

The 2 glasses are in contact.

Detection?

Are there variations related to the angle α , between $y'y$ and NM-SM?

Exercise 2: We take the plane P and the lens with a vertical $x'x$ axis

We place 4 glasses whose axes $y'y$ and $z'z$ intersect at O on the $x'x$ axis, yy' and zz' are perpendicular.

Determine the places where eifs are detected.

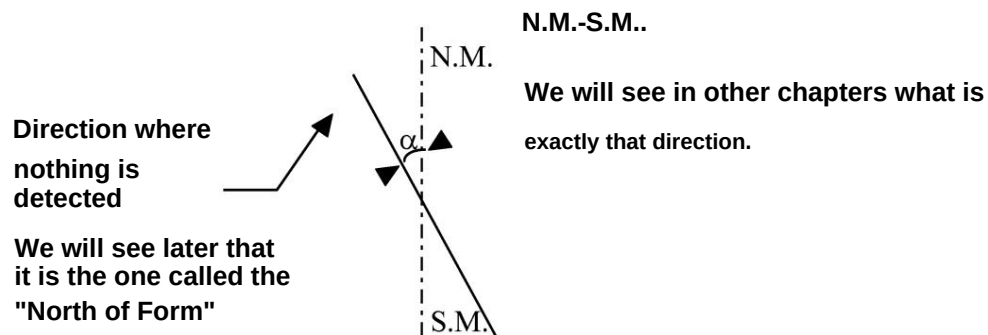

Answers exercises 1

- b) Nothing is detected above the table nor below in a region close to the glass ; on the other hand, on this axis, we detect clearly more above P. We do not detect nothing below.
- c) The detection is done on the $x'x$ axis of the lens over a much greater distance than above and below.

Remarks :

- 1) the denser the material, the further away one detects. Naturally intervenes also the neighborhood of the form.
- 2) a detection taking place in a certain neighborhood around a shape F, when we have clearly delimited this vicinity, we must not stop there. In effect other regions of space having no common borders with this neighborhood may arise.

d) An eif - or eifs - is detected in all directions except one which is close to the

e) We no longer detect anything on x'x whatever the horizontal position of y'y.

On the other hand, we detect eifs on the y'y axis but nothing neither in y'y nor in the directions Form North-Form South.

Answers exercises 2: We detect along x'x but not along the 2 axes y'y and z'z.

The detection following x'x seems "stronger" than that in the previous exercise.

Note: This feeling of "stronger than" will be to remember. We can then set a scale, for example, we will see in the following pages, from 0 to 204. We can even have multiple values on this scale, i.e. a spectrum of values, discrete or of bands, which is richer than what the measurements for the objects give usual techniques. But we will notice that we did not impose a scale a priori; she made itself felt, imposed itself little by little. This is how concepts are constructed. in this domain.

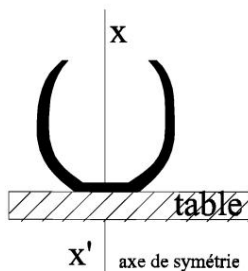

Advice :

- a) It is preferable for beginners, during these exercises, to work on a table rather than on the floor. Detections on a parquet - or close to the ceiling - are also possible but the eifs are often "attenuated" in such arrangements.
- b) We will check that we detect the eif in the axis of the glass, under the table.
- c) We hold the pendulum in the right hand, we indicate with our left hand, the outstretched index finger, what one is looking for. We take care that the index does not enter not in interaction with the phenomenon to be detected.
- d) If the glass is replaced by a coil, the detection is the same.

Note: When we are used to handling a pendulum or rod, we can thinking about the problem, without moving around, without pointing with your hand to the very places where one must detect the effects of the eifs, the answers will come immediately.

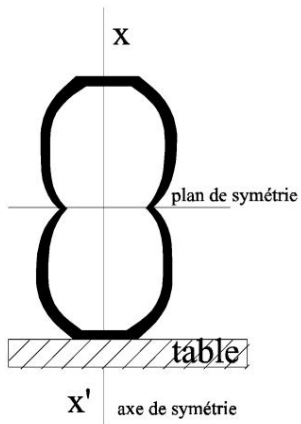

Exercise 3: Consider a stemmed glass.

- a) What can be detected along the axis of symmetry $x'x$?
- b) We work with a glass of the form

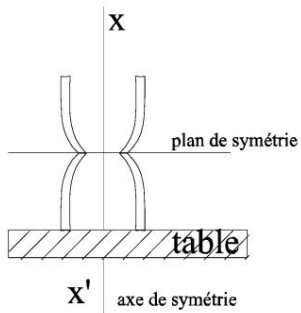

axe de symétrie

c) Other assembly

d) Same with an egg cup open at both ends

Answer exercise 3:

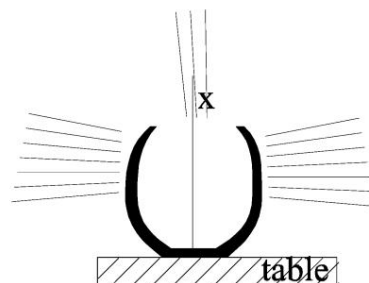

a) Nothing is detected on the axis of symmetry, on the other hand, we detect

on the part indicated below

table

b) Detection along the axis and a little on the ends

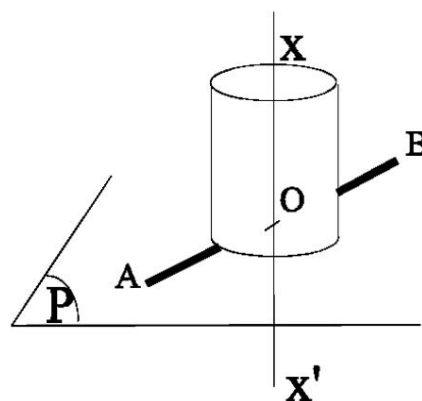

- c) Detection along the axis. Nothing following the plane of symmetry.
- d) Detection along the axis and a little on the ends. Nothing according to plan symmetry.

Note: If you put an egg in the egg cup, everything changes. It changes according to

que la forme œuf est pleine ou creuse et la nature des eifs va être liée au fait que l'œuf est réel, artificiel, plein, creux, coloré en surface, etc...

Exercice 4 : On trace sur une feuille blanche un trait noir accentué.

A

- a) AB and $x'x$ intersect at O. We rotate AB around O. What happens the?
- b) If O is not on $x'x$ what do we detect?
- c) We draw CD passing through O and perpendicular to AB. Detect places where the eifs are detected.

Answer exercise 4:

- a) We generally detect one or more eifs following $x'x$ - O is on $x'x$ and AB - By
against if AB is following the North of Shape-South of Shape we no longer detect
nothing on $x'x$, nothing on AB or anywhere else.
- b) If O, which is on AB, is not on $x'x$, we detect in addition to eifs on $x'x$
eifs in one of the half-planes bounded by AB.
- c) O is on AB and on $y'y$ and $z'z$. We always detect on $x'x$ but there is nothing if
the axis North of form-South of form is a bisector of the Cross of Saint
André formed by $y'y$ and $z'z$.

Tip: Regarding the training in the manipulation of the pendulum and the rod it need to practice:

- the 1st week V4 of hour per day
- the 21st week 1A hour per day
- the 31st week % hour per day
- the 41st week 1 hour per day
- and after, as long as you want.

This progression avoids getting upset.

After about 300 hours of practice, you are sure of your answer if the questions are correct. posed.

Note: Sometimes we have a feeling of "more or less intense" about the eif. It is a simple sensation, nevertheless it is useful.

Because the eifs are delocalized, therefore not identifiable, there is no intensity associated with eifs.

One could try to place a scale equivalent to a scale of intensities but without unity.

So we will operate as follows.

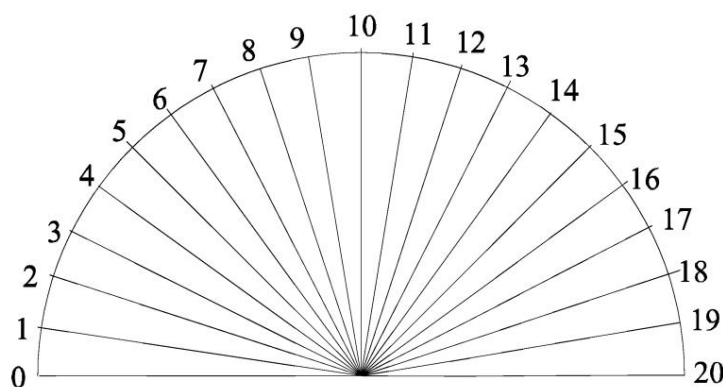

Schéma imaginé par André Philippe⁵

We draw on a sheet of paper a semicircle and a diameter as well as 20 equal sectors numbered from 0 to 20. In the case of the eif - or eifs - detected on the axis of the cylindrical lens is given the sector [0,2]. Then we replace the glass with

5 A. Philippe worked with Jean de la Foÿe .

a solid silver beaker, also cylindrical, placed in the same place; we
looks for the sector corresponding to the eif detected on the axis of the timpani - or the
eifs

We find for example [9,10[or [15,16[.

We will say that the eif associated with the timpani is of "intensity" greater than that detected on the
glass.

It turns out that this scale is quite stable (this scale is reproduced at the end of
booklet on an isolated page in order to facilitate its use). But you don't have to
deduce that one can place such comparative scales on any
manifestation of eifs or states - as we will see later -.

Yet this is what many researchers happily and routinely practice in this
realm of forms. And they speak in more units: d'angströms, de
centimeters, - units of length since they want to talk about waves and therefore lengths
from where -.

On such a diagram one can also place the vitality of an individual. We will "measure"
vitality.

It should be noted here again that the concept of vitality felt by everyone cannot be
compare from one unit. Different people can agree on
from this "vitality" on the state of health of a patient. So it still has a
usefulness.

~~Story from the comic strip Spirou: _____~~

Sometimes he passes information in books, newspapers that seem trivial
but are very uplifting or profound if one has the right frame of mind.

It should not be inferred that this message is intentional. Simply its author read,
during the time of the creation of his work, more brilliant than he had ever been and
maybe he never will be again.

If we think about the RBB's point of view on unorthodox research, let them
classify in the field of the irrational, therefore of debility, which is not measurable
is nonsense, a result of phantasmagoria.

Fortunately it is not always so. And a form, an object have different functionalities according to the representation or the type of thought making it possible to describe them, use them.

In this short story (see end of the booklet) presented in the form of a comic strip, the child expresses in correct language what he extracts from the book. The Viking leader takes over what says the child, places him in his representation where it makes no sense since for him the book is not an instrument from which one can extract information. And actually the leader asks a question that is not consistent with his personal representation. He falls into the absurd. This provokes laughter but the RBB laughs without knowing what he is laughing at. He laughs out of habit. The comic for him must contain a reason to laugh; even if he doesn't have access to the reason for the story, he laughs anyway. The story will thus have satisfied everyone world !

ERRATA Issue 1 - year 1997

Chapter V

I. Detection devices

We will see later that certain forms, and living forms, require, so that we detect their eifs, states, what Jean de la Foÿe called an "artifice".

For example to test a potted plant, it is necessary for some tests to lean the plant, for a tree direct the left hand towards the tree, thumb bent on the little finger, the other three fingers outstretched.

For Jean de la Foÿe, the form seems to select or channel one or more eifs of the space surrounding the form. Space is thus, at every point, filled with possibilities potential.

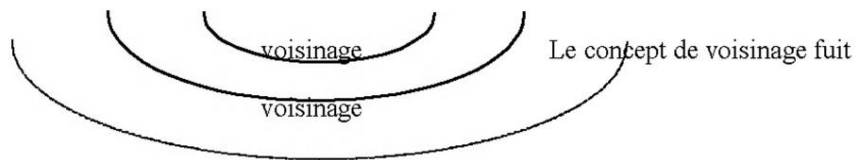

This idea had been launched at the beginning of the century by Nicolas Tesla who said that we could draw energy from any point in space.

Here it is not about energy but there is therefore a double possibility: from each point of space one draws energy or one draws eifs, and perhaps from these eifs one can draw the energy?

Energy is measured, there are units: joules; erg. Eifs are not measured. We detects their effects in certain places.

The form emerges or submerges in the AND structure. It is this process that is expressed by eifs, by states. But completely emerged forms, for example a full ball, a full cube emit eifs in certain neighborhoods. What we detect is actually linked to a neighborhood.

Can we find the neighborhood, describe it? Usually the answer is positive. We realizes that this neighborhood is immersed in another but the process is not recurrent ; quickly the concept of neighborhood vanishes and we arrive at an emergence linked to the ball or cube shape.

U. Les polarités

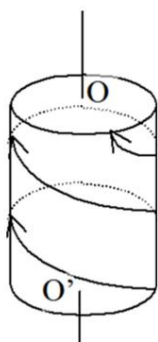

One can associate to a form, to the forms or to a system of forms, polarities; he should not be confused with those of the magnet where in rational thought are specified **2** poles therefore polarities, one for the north pole, one for the south pole.

Naturally more or less dowzers or "Ondiformists", when they have heard of polarity about shapes, have confused those of magnets with any system they were testing and they added "These are indeed the same as those of the magnets since I find them identical".

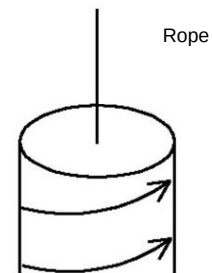

There had crept in a profound error. If we have in mind that they are identical or same type, they will automatically be found identical.

So let's eliminate this error.

For this let us consider two pendulums γ easy to realize in plastic material enough dense, γ cylindrical.

Polarité +

Polarity -

Suppose there are 2 strings, one fixed in O and the other in O'.

Note: it should not be said that by holding the pendulum by the string fixed in O or by the string fixed at O', the direction of rotation of the propeller is changed. Let's not forget that a Right-hand screw stays right-hand no matter how you hold it.

So we really need two pendulums to define the polarities.

Exercise 1: A human being has polarity + on the forehead and polarity - at the barrier of the head.

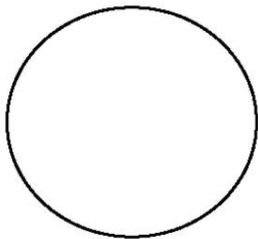

- a) check it
- b) what is found on a statue of Easter Island? (cf. copy at the end of booklet)
- c) Are there human beings for whom the polarities are reversed?

Answers

- b) There are no polarities
- c) the answer is yes. They are, as we will see later, often linked to harmful states.

Exercise 2: We give ourselves a circle in a plane. We impose NF and SF as on the design.

Find the polarities.

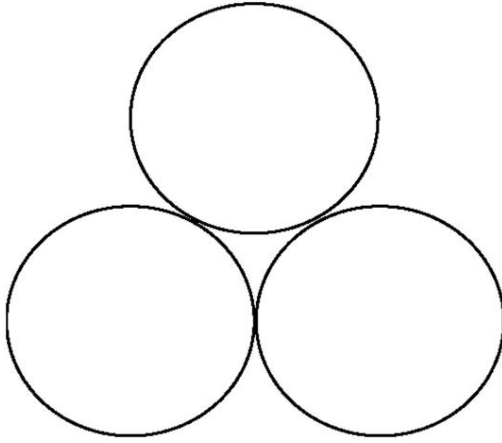

Exercise 3 :

- a) We are given 3 tangent circles as below with the NF, find the polarities.

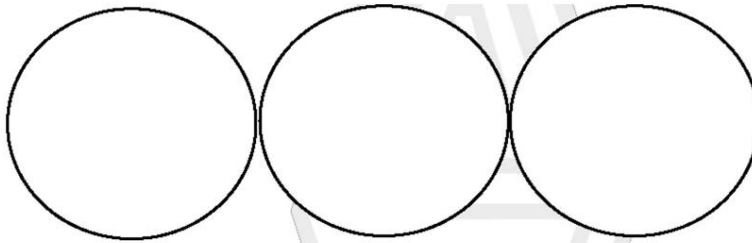

Course for "Title" "Name"

© EÜRECALL

o

b) We give ourselves 3 circles as below. What can be said about the polarities?

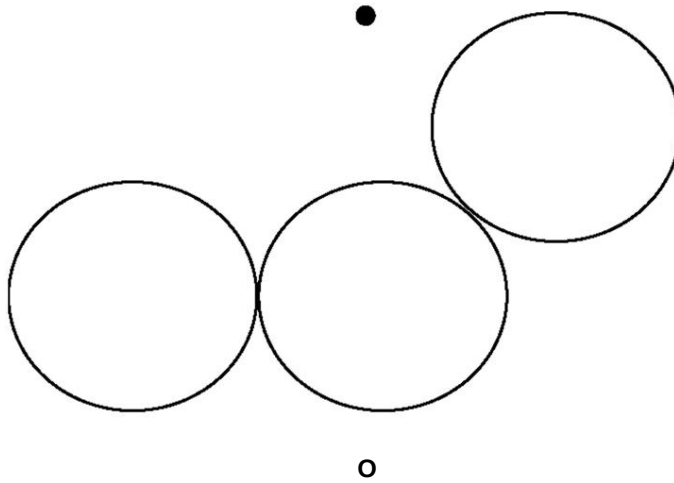

o

Course for "Title" "Name"

© EÜRECALL

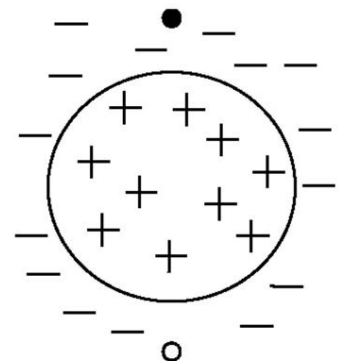

c) We give ourselves the 3 circles as below as well as the NF, SF.

Advice

- 1) It is necessary to impose the NF because we will without knowing it give the answer by relative to the top of the sheet, which is a way of imposing the NF But in this case the observer can move relative to the sheet which can change or not the result while if we impose the NF, the results are definitely fixed.
- 2) On the sheet where the figures are drawn, place the black and white dots correctly imposing the NF, on the upper and lower edges, far enough from the figures of so as not to disturb them.

Answer exercise 2:

Réponses exercice 3 :

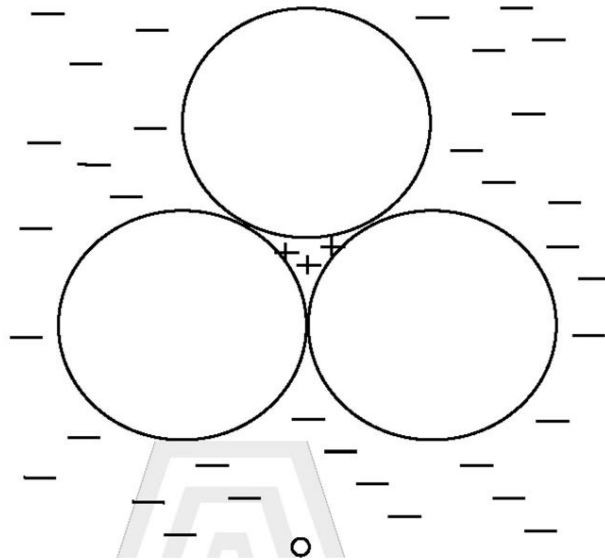

- a) The interior of the circles is neutral. If the position of the NC is changed, the polarities change. We can then test the following assertion: The polarities are a function of the position of the observer with respect to the shape! The

Course for "Title" "Name"

© EÜRECALL

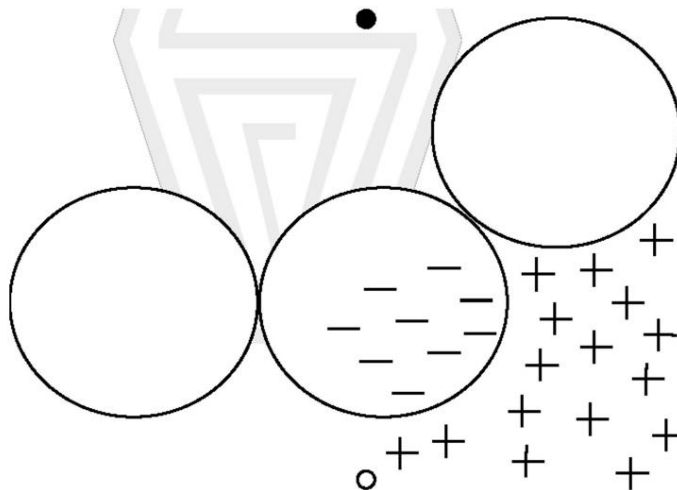

position of the observer in relation to the form can be thought

differently: the shape changes according to the position of the observer. This is the rational point of view which imposes the stability of the form in existence by relation to the observer.

b) In this arrangement, there are no more polarities

c)

Problem: We give ourselves a wooden disc, pierced right through in its center and a needle is centered in the hole

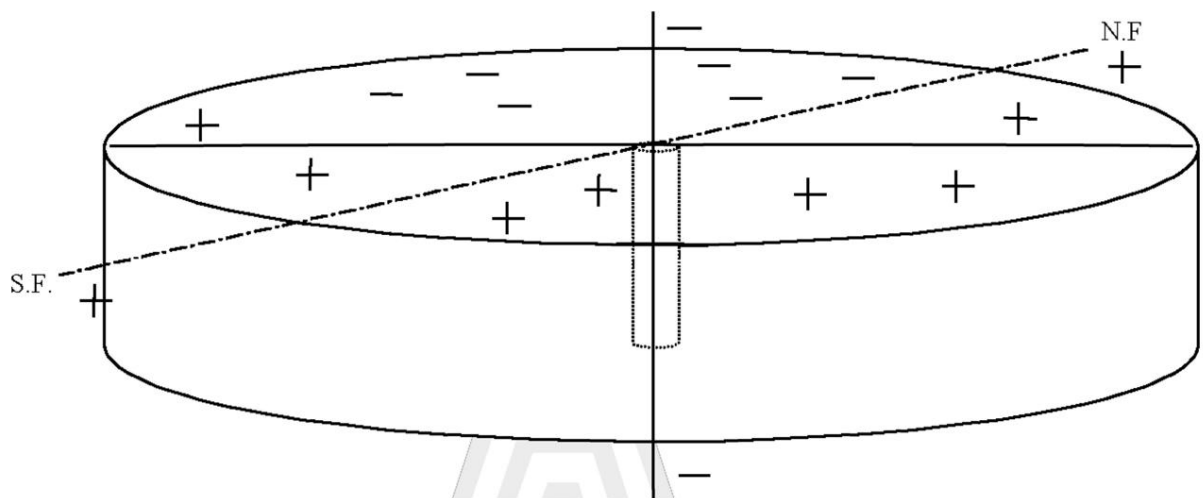

a) Study the polarities

- on the tray
- on NFSF tax
- on set tax

b) Study the eifs

Corrected:

a)

b) Here at the SF we detect eifs; they correspond to the differentiated colors.

There is a 40° angle west of NFSF Tax which negates all polarities.

Jean de la Foye calls it the angle of equilibrium.

If $2R$ is the radius of the disc, with a needle smaller than the previous one, that is to say with a radius a little less than R , we do not detect a "body polarized" $\gg 1$

III. The tree trunk

Consider a tree with a vertical, cylindrical trunk. Let's cut the trunk of this tree by a plan horizontal.

Let R be the radius of the trunk.

Let's draw a concentric circle of radius $2R$.

1See the tree trunk

On the circles of radius R and $2R$ we will detect eifs.

Let us point out immediately that we do not detect on circles of radii nR with n positive integer greater than 2.

The detection is done by artifice, for example the outstretched left hand, the fingers suitably arranged - it has been described previously Thus the spectra go appear on each of the circles.

It is good first to locate the NF.

Definition: We will say that the polarized body and the aura are virtual when an artifice is needed to detect

Then, let's find them:

- Circle of radius R : the undifferentiated spectrum is detected.

At NF we find the $V+$, at the SF the V , at OF the R and at the EF the V_i .

The other colors are arranged on the circle.

- Circle of radius $2R$: at NF we find the $V+e$

at SF we find $V+m$

at the OF we find $V'm$

at the EF we find $V'e$

Course for "Title" "Name"

© EÜRECALL

We send an eif according to Tax x'x.

Consider the positive helix:

Check that if we send an eif in M following x'x, it stays in M. If we send an eif in E along x'x, it remains in E.

There is conservation of the eif.

Consider the negative helix:

Check that if we send an eif in M along x'x, it goes to E and an eif in E, it goes to M.

Everything happens as if we made a symmetry on the tree trunk in relation to the centre.

Exercise 2: We start with a candle that Your lights.

1. Check that we have a polarized body and an aura if the candle is lit and that the polarized body is virtual
2. Check that if the candle is extinguished, nothing is detected even with artifice.

Exercise 3:

- a) We take a crystallizer in which we pour a soda solution then a sulfuric acid solution.
 - Check that a polarized body and an aura are detected around the crystallizer both real, so there is no artifice to put in place to detect
 - When the reaction is complete, check that nothing is detected.

Reminder: The reaction is:

- b) We start from a crystallizer in which we always pour a soda solution but second we pour acetic acid
 - Check that a polarized body is detected as before without artifice and a real aura.
 - Verify that the polarized body and aura are detected all the time; this must be related to the fact that the reaction is balanced.

Reminder: The balanced reaction : $\text{CH}_3\text{COOH} + \text{OHNa} \rightleftharpoons \text{CH}_3\text{COONa} + \text{H}_2\text{O}$

"All doctrine goes through three stages.

We attack it first by finding it absurd.

Then we admit that it is true but insignificant.

Finally we recognize its true value and
its adversaries claim the honor of having discovered it.

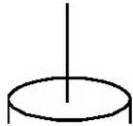

August Light

\

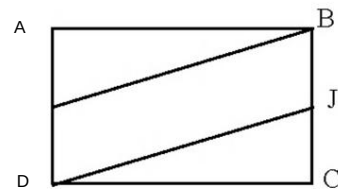

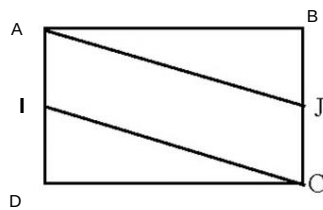

IV. A few clocks

To detect the polarities 2 pendulums are necessary. We start from a cylinder of diameter of that of a broomstick.

— Length: 4 cm

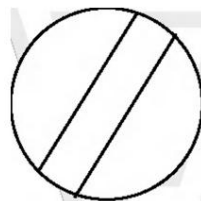

And we trace on a rectangle of paper ABCD which will cover the cylinder the segments AJ and IC then IB and JD.

I and J being the respective midpoints of AD and BC.

We thus have each helix.

If we start from pieces of a broomstick, which are made of wood, we must draw on the face top of the cylinder 2 parallel lines which remove the polarity of the wood because everything

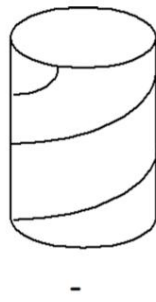

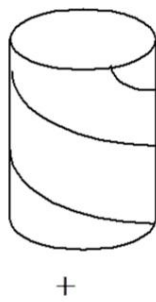

piece of wood has a polarity.

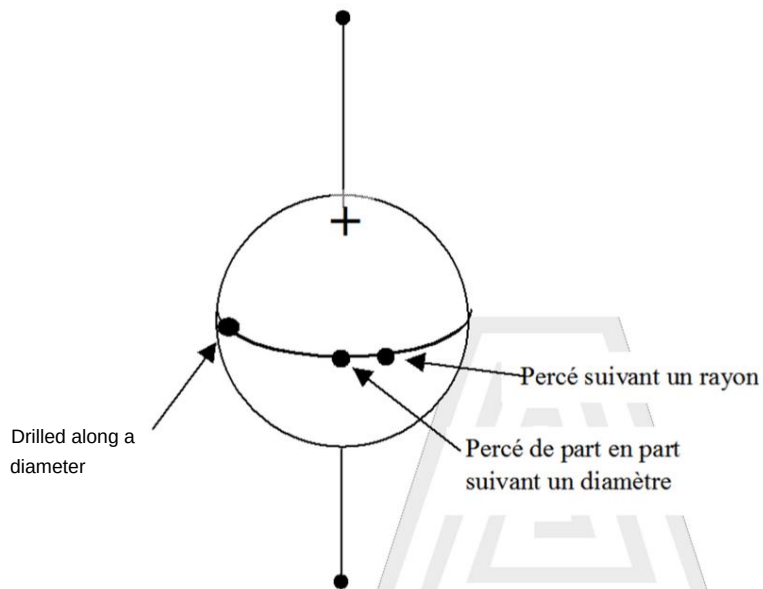

These two clocks were designed by Jean de la Foÿe.

Another was developed by Raymond Montercy. It also gives the polarities.

The advantage over the previous ones is that there is only one.

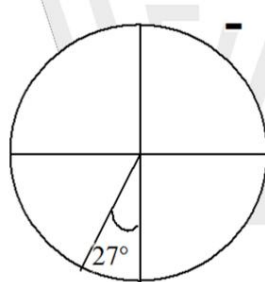

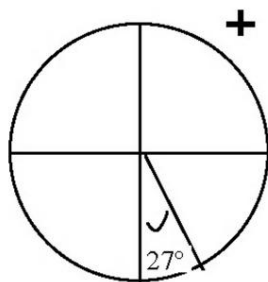

Pendules des polarités de Jean de la Foÿe

Pendulum of the polarities of Raymond Monterey

The string crosses the sphere right through, this which makes it possible to spill. In this

position, the + at the top, we detects polarity + and reversed, the $\ddot{y}$ is up, this is the polarity $\ddot{y}$.

v. *A few comments*

1) The stones in the countryside have polarities, the pieces of rock the same.

This can be used to rebalance the places; for example a house that has harmful eifs can be made pleasantly habitable by placing stones in the garden of this house; we look for the polarities of the stones and we arrange relative to each other.

2) When placing the first stone, you must already have found out how many will be needed, maybe 2, 3... And place the first knowing that you will have to place 2, 3...

3) When all the stones are in place, we will check how it goes in the house, if that is what we wanted.

4) You have to ask yourself the question of what will happen in the following days, the month following ; in fact, this reinstatement shakes up an established order; there may be repercussions.

5) But it is not easy to rebalance only with stones

6) We know that we are in a domain that is not rational. We started from the concept of polarity which involves our world of duality. Suppose we are talking about polarity without imposing a dualistic view.

So we can find shapes with one polarity and more than 2 polarities. We have discovered such forms with a positive or negative polarity, with a negative and 2 positive etc...

The study of forms contains many surprises; we discover it especially if we does not impose rational patterns too much.

VI. A few tips

- 1) In dowsing one will notice certain particular points: those where two currents of water intersect - in vertical projection on the ground because they are not necessarily same level. At these points it happens that pendulums and rods react differently, as if we wanted to point out a peculiarity to the manipulator, and it is!

We also have another peculiarity, it is a point on the ground where vertically finds an upwelling with pressure from bottom to top.

These points can be life-threatening; a "strong" V'e is detected ; and other something that we will see later: this is called the "Knot of Life".

- 2) The mancies, in particular the dowsing, are without limit. So after detecting the water current, the favorable point for drilling, the depth, one can search for the flow rate, temperature, mineral salt content, pH and the variation of these properties with the seasons etc... Thus we can search for any physical parameter or chemical as one imagines.

Let us not forget that this research can only be carried out successfully following a training and also it should be pointed out a specialization. Thus some become specialists in finding lost objects, they have amazing successes; others specialize in breakdowns of various devices such as television sets; for still others it is groundwater detection

Naturally all these people have the "language of the dowser". They try or not not attempt to explain what they are doing; the best is that they leave aside all attempt to explain, what counts is the success and often they are valid.

- 3) The search for water can be a training topic for beginners except if they work with a professional dowser whose detections are always followed by a drill otherwise you never know if you got it right.

So we'll practice finding the depth of water in an existing well. We check afterwards with a weighted string.

Then we will look for the currents feeding the well. We will reproduce the whole following a drawing on a sheet of paper and we will see if on these currents found do not

Course for "Title" "Name"

© EÜRECALL

find no other wells.

We will see if houses are built on these currents, if they have cracks.

We will seek to know more about the health of their inhabitants.

We must not make a law about the conditions and the health of people living in houses located above underground water currents.

It may happen that the shape of the house annihilates any V_e , that the orientation of the running in a neighborhood surrounding the house make that there is no V_e , that the composition of the basement is the adequate balancer.

As we have already pointed out, beware of hasty generalizations.

The same is true for high voltage lines. The high voltage line sends V

E .

The range of this V_e depends on the orientation of the line, the neighborhood etc...

In the worst cases, a 100,000 volt line sends a V_e about 80 meters away.

200 000 volts	150 to 160 meters
400 000 volts	300, 400 meters
800 000 volts	600 meters

- 1) The ever-popular search for water has been supplanted, given the number of followers, by requests on health issues.

After 300 hours of training - it takes about 300 hours to be sure of his answer - one can be quite sure of oneself.

The interest of manics in health issues no longer needs to be demonstrated: at the of the family, at the agricultural stage, at the veterinary stage.

We gain autonomy and also an economy that are not negligible.

It should not be inferred that classical knowledge in human medicine and veterinarian are to be rejected. They are perhaps less necessary because we will only few diagnoses of symptoms and diseases but above all diagnoses therapies.

That the sick person is sick is very often known. You have to work with

Course for "Title" "Name"

© EUREECALL

homeopathy, acupuncture and in this case the mancies make it possible to direct on points which are not the points usually listed.

About people who claim to have no results with homeopathy, they can either refuse homeopathy because for them it is quackery, so the homeopathic products they take are annihilated in their body by their refusal of this way of treatment, or being too intoxicated by allopathy and its remedies, either we come across people who smoke a lot or use hair dyes. Chemical means of contraception can also be homeopathy disruptors. Similarly coffee, tea, mint are sometimes contraindicated.

It can therefore be used in the right dilutions of homeopathy. We will use also Schussler salts and trace elements - in marketed form:

Oligosol -.

We thus have more than 100 remedies to which we will add a few remedies specific homeopathic medicines and some complexes from Lhening laboratories.

We can help ourselves with publications such as homeopathic dictionaries: that of Apple tree for example.

It is necessary to start from the idea that it is necessary to find the remedy of which the patient has need - so the pendulum will look for which Schuesler salt is suitable to administer or what Poconéol will be specific -.

Schussler's biochemical salts are 12 in number. They come from the trituration of minerals composing the living organism; trituration is at 6 CH.

Among them, three are trituated at 12 CH.

Oligosols are simple or complex trace elements. They are among 15 approx. There are also sulfur and silver Granions.

Poconéols, Shuessler salts exist in the form of small tubes. These will serve of witnesses.

2 Poconéol: homeopathic complexes developed by Father Bu's team, these complexes took the name of Poconé, city of Mato-grosso. They are at 5 CH; low dilution ensures safe handling.

This therapy was pioneered by missionaries who were not doctors.

Course for "Title" "Name"

© EÜRECALL

Suppose we have a collection of witnesses, we proceed as follows:

- we launch the pendulum in oscillation and we place it above witness n° 1 in knowing that we are intervening for such a person
- Two cases:
 - The oscillation is maintained so it is not for the person
 - We move on to gyration: it's for the person.

Whatever the case, we go to witness number 2 and we do the same thing.

- Let's make a bunch of valid witnesses for the person, for example the N° n, p, q.
- We then see if 2 to 2 is still valid, if the set of three is still valid.

In fact, in certain cases, such assemblies may not be valid for the person.

- It is then necessary to see at what times the witnesses who have been retained must to intervene.
- In addition, as the days, weeks, months go by, it will be necessary to retest. From stored cookies may no longer be valid.

Tip: Consider drainers, e.g. Poconiol No. 1 and

7.

Drainers are ignored by allopathy. An intoxicated organism must first be cleansed of flocculáís and toxins.

To the drainers one will add, possibly, a remedy against the constipation.

- Chlorumagen
- King of Pilules
- Sulfur flower powder in honey. The honey should be good quality. Avoid touching the honey with an instrument metallic.

It is always necessary to fight against constipation whether it is temporary or permanent.

Finally, always follow the evolution with the pendulum - or the stick -.

CHAPTER 6

The Vital Field

Introduction

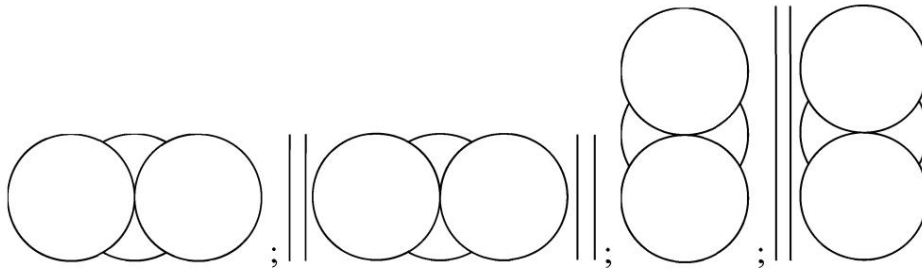

Jean de la Foÿe tried to characterize living systems. For this he has set up this which he named: Champ Vital.

We will present it in what follows.

The Vital Field

It was therefore designed and set up by La Foÿe.

The vital field has 4 components which are detected for each from one of these forms.

The first of these forms is called the "Knot of Life".

Components without the vertical bars are called M-type components.

Components with vertical bars are called E-type components.

The vital field is not quite complete in its description. It's necessary :

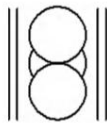

- place the 4 components along two perpendicular line segments.

N.F.

° - Fy CD

CDU “

SF

- vertically to the intersection of the 2 line segments, a letter is detected

Hebrew: תשׁ/1 (schin)

It must be pointed above on the middle branch — which is not found in Hebrew where the dot is either on the right branch or on the left branch —.

, Thus on a living being, one must detect this vital field.

The node of Life is therefore composed of 2 circles of equal radii, tangent externally and at the point of tangency as center, we trace with a compass 2 arcs of circle of the same radius than that of the other two.

1 The 2 perpendicular line segments as well as the representations of the 4 components of the vital field are not enough to set up the schin pointed in the middle

Remarks :

- the node of life is detected in the living human being at the level of the left temple and from the navel.
- if it is dead, it is detected at the level of the mouth.
- if you put a coin in the dead man's mouth — a custom of ancient peoples — you no longer detects anything.
- if we do the same experiment on a skeleton, we detect nothing, neither on the temple left, nor on the location of the mouth.

On the other hand, if we intervene from a photo of the living person but who is long since deceased and for which, after death, he was placed in his is mouthing a room, so nothing can be detected on the photo at the level of the mouth.

The photo gives an indication that we wouldn't have from the skeleton.

- On people in prayer, in deep ecstasy, we detect the knot of life on everything the face.
- On deceased persons, having worked a great deal in fields not orthodox, it happens that we detect this knot of life, even from a photo, on part of the head.
- On animals such as cats and dogs, it is detected at the level of the muzzle and navel.

But it happens that for these same animals it is detected at the level of the temple left. They then have close contact with a human being. It's not a transfer.

It should be understood that the usual classification in the scale of values, constructed in such a way that the human being puts himself in a good position, is not at all valid in the area we are discussing here. We need to see a lot more, if we don't considers that the animal scale, paths with no possible scale of comparison, but with at times, for some individuals, possibilities of understanding - it's not imitation -.

Those who are very interested in and like animals alike understand very well what we are presenting. Of course it is not these animals — especially dogs — which are dominated by their master and subject to stupid obedience to a few commandments.

These animals there are sacrificed and are a imitation of those of which we have spoken here above.

- Concerning cattle, sheep, the life knot is detected at the nostrils and at the navel. The same for the horse.
- When the animals are dead, in general, the life node is no longer detected.
- For animals like the elephant, the life node is detected at the level of the end of the tube, at the left temple, at the navel.

It was the same for animals now extinct like the mammoth, the mastodon.

- Regarding human beings, the wearing of certain caps, kepis, brings the knot of life in the middle of the forehead. Similarly, the red dot worn by women in India on place in the middle of the forehead.

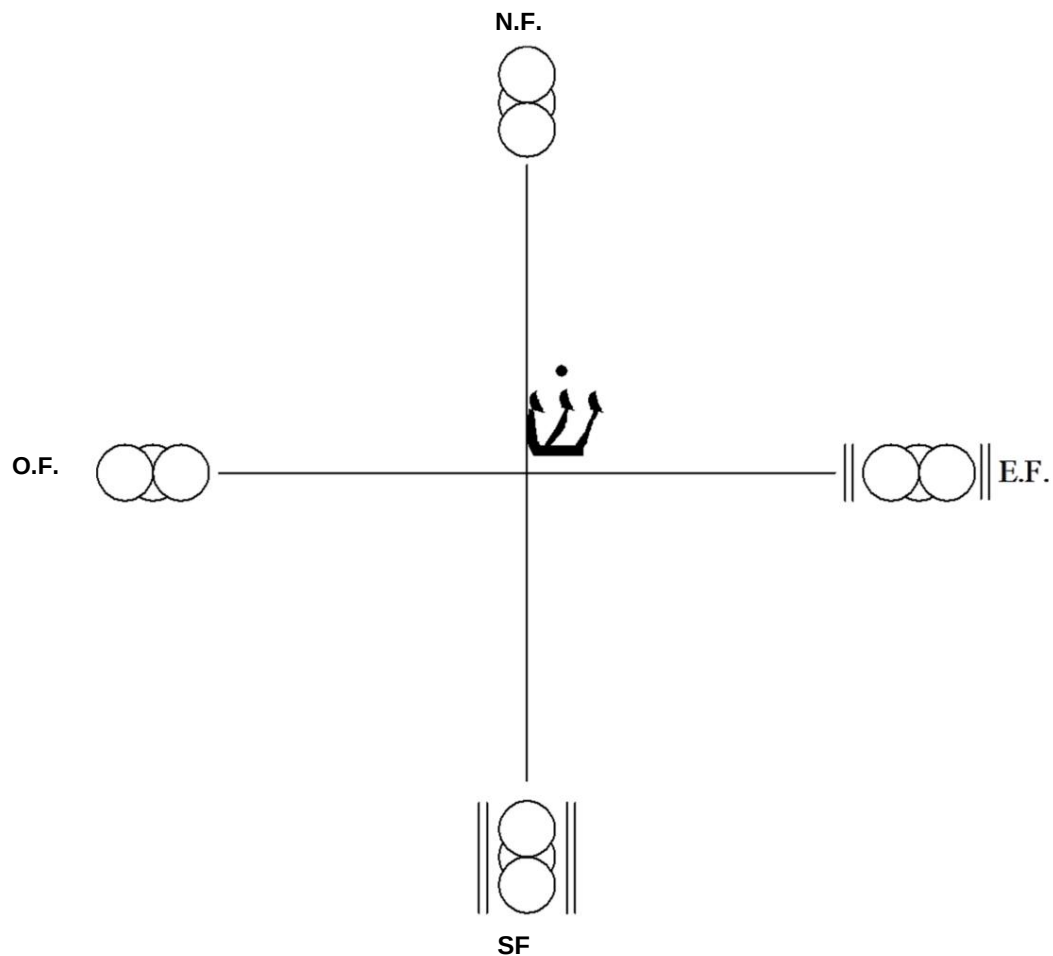

More generally, it is possible to find multiple shapes that move it in multiple places.

The fact, for a man, of placing it in the middle of the forehead favors his ascendancy over other human beings.

It was not calculated, or maybe the reason passed on then to a moment has been lost but the habit of wearing this type of headdress has remained, or again, the human being instinctively puts in place what corresponds to deep intentions. The 3 hypotheses exist simultaneously.

- The vital field on a human being, if it is detected on a witness of the person: passport photo, lock of hair, etc. is fixed even if the person moves when you take the test; it may be millions of miles away, that doesn't does not interfere with the test.

If the person is in good health, we find:

but it can happen that this vital field has its components which turn, the figure around the center rotates through a certain angle a positive or negative

Components can interchange, either the usually horizontal ones interchange between them, or the usually vertical ones switch between them.

When the two axes rotate through an angle a clockwise, a $> 70^\circ$ one must watch carefully if this rotation over the months continues. There is a weakening of the subject with which this vital field is associated.

In the case of cancer patients the rotation continues to increase even more in the negative direction, but a vital field which has for example rotated by 170° does not necessarily correspond to a Cancer. However, large negative angle rotations or permutations of horizontal components should suggest the possibility of cancer.

The permutations of the vertical components correspond to quite another thing. They were detected for the first time by J. Ravatin on a plant associated with a form. They

correspond to the index of another form of life that the human species does not seem know in our time and that this plant had taken for a short time.

The vital field, when an individual turns on itself also starts to turn with a delay and in the direction of rotation of the swivel.

A dancer turning rapidly on one foot catches up with her vital field.

We remind you that if we test the dancer from a witness of her, we will not find the simply rotating vital field, it will be that associated with the human form that is the dancer.

Remark :

We insist a lot on the precautions to be taken before any test:

- the precision of the question,
- knowledge of representation.

The vital field for a human being presents its components NF, SF following the direction of her stare.

- If he looks in front of him, as soon as his head turns, the vital field follows the movement always with a slight delay and always quite slowly.
- If the person tilts the head, or lies down, the vital field remains in a plane horizontal.

However, certain directions of his gaze without head movement may change the position of the vital field.

- Realization to test the vital field:

We stick on a wooden board a sheet of white paper on which we have drawn a graduated circle and imposed the NF..

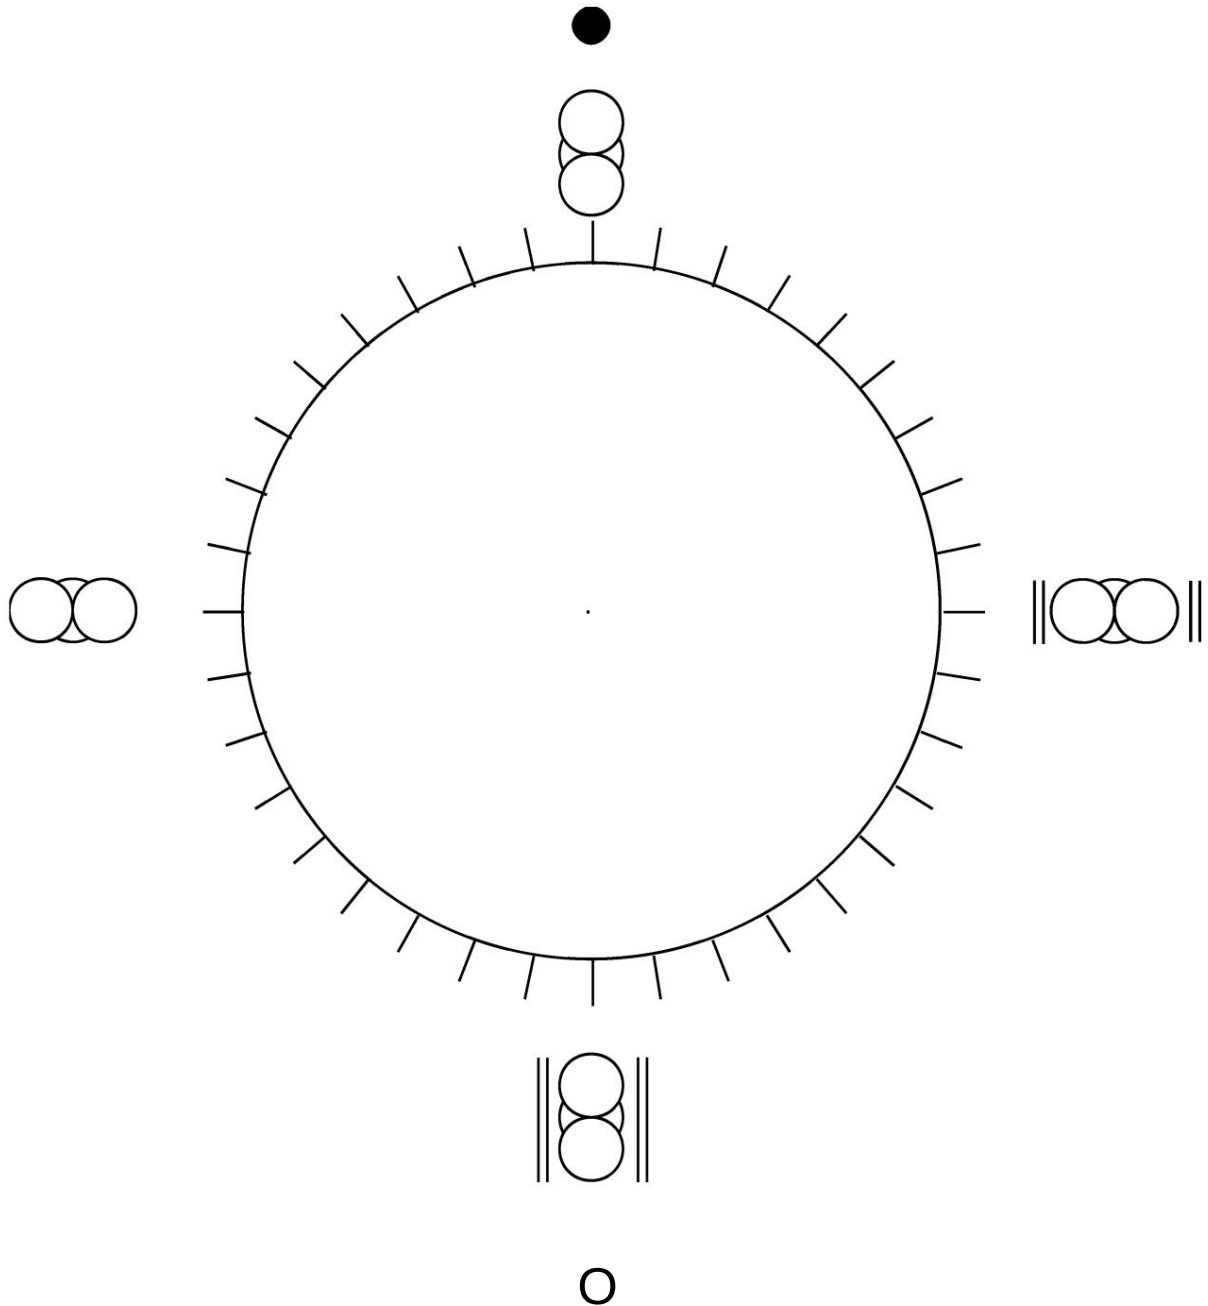

Remark :

Forms (HD IICXDII) should not be shown on the drawing as they would impose always the vital field following the correct position.

You need to be able to check whether it has rotated or deformed. However, we must not forget to impose the NF..

We place the witness in the center: leaf, lock of hair, etc...

One must detect, if the living witness is in good health, the schin 2 - pointed in the middle - at the center, above the witness.

Remark :

The planchette does not have to be drilled in its center.

The diameter of the circle may be around 30 cm.

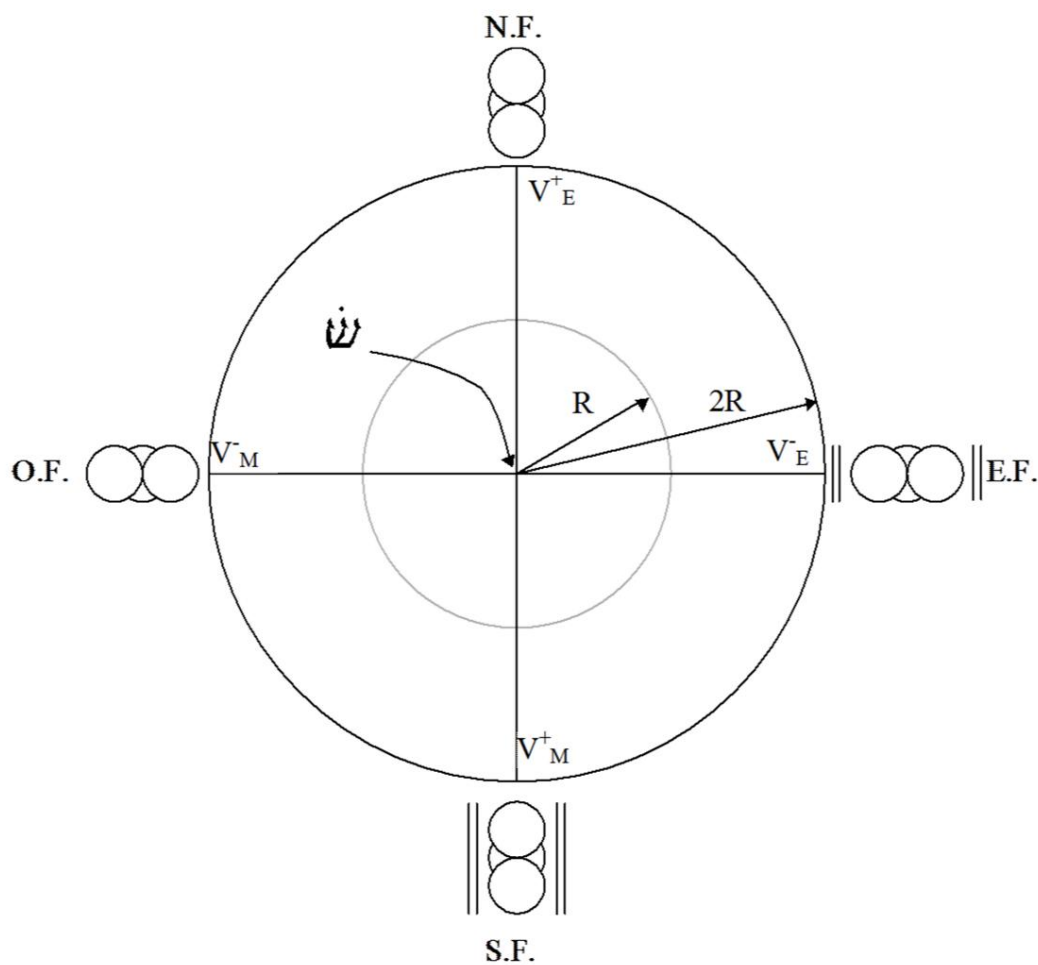

2 This letter does not exist in Hebrew dotted in the middle; it is pointed either to the right or to the left; nevertheless, it is necessary to point it in the middle to have a response by command: Jean de la Foÿe had found this aut - aut is the Hebrew number for letter, and it seems that it is preferable to use this term because we realizes that an aut is much more than a letter in the sense we understand it in the usual C. de C.

The detection of the vital field is quite delicate. She must approach herself calmly and always without preconceived idea.

Exercise :

- 1) The vital field will be detected on the “tree trunk”;
- 2) Consequently, it will be detected on the candle lit with artifice, on the tank where the acid + base reactions and there without artifice. It is advisable to redo these experiments.

Corrigé :

Remark :

There is no vital field associated with a menhir.

Standing stones, dolmens and sites like Stonehenge and many others around the world cannot be approached with impunity without a deep intuition of the other C. of C. where other concepts, absolutely foreign to ordinary thought, must intervene.

We recently found that the menhirs are linked - or thanks to the menhirs one is linked - to something that looks like a field. This can only be detected when we have consciousness of this "almost-field".

The Ancients used concepts which are not in the rational C. de C., therefore a mance cannot answer anything about these concepts. She always uses a representation and none of these concepts fit into the usual representations.

It is not enough to say "I work on shapes, so everything associated with shapes accessible to me".

We have discovered properties of fairly banal shapes as we go along. researches and when the new concepts were found by us, the forms gradually revealed.

Concepts were developed from necessity and necessity is partly made from work on shapes.

In reality, the 2 processes are carried out simultaneously; the necessity is fundamental between the of them ; but it's a special move of the mind and if you don't use it, nothing comes out of these fundamental and profound discoveries is not realized.

For example, on each page of this course is presented in the background a form called IDALAB. Idalab has amazing properties.

It emits, worn for example as a pendant on the skin, eifs which will not be presented in this 1st year course, say at very high levels and listed as VC, FV and more what we call lfs: LD, LA, LC, LB, then the Avœcum and finally a field that we name the field ZD (Dynamic).

People, supposedly very competent in the field of forms, being in Swiss claimed that this Idalab form was commonplace, even harmful in some cases.

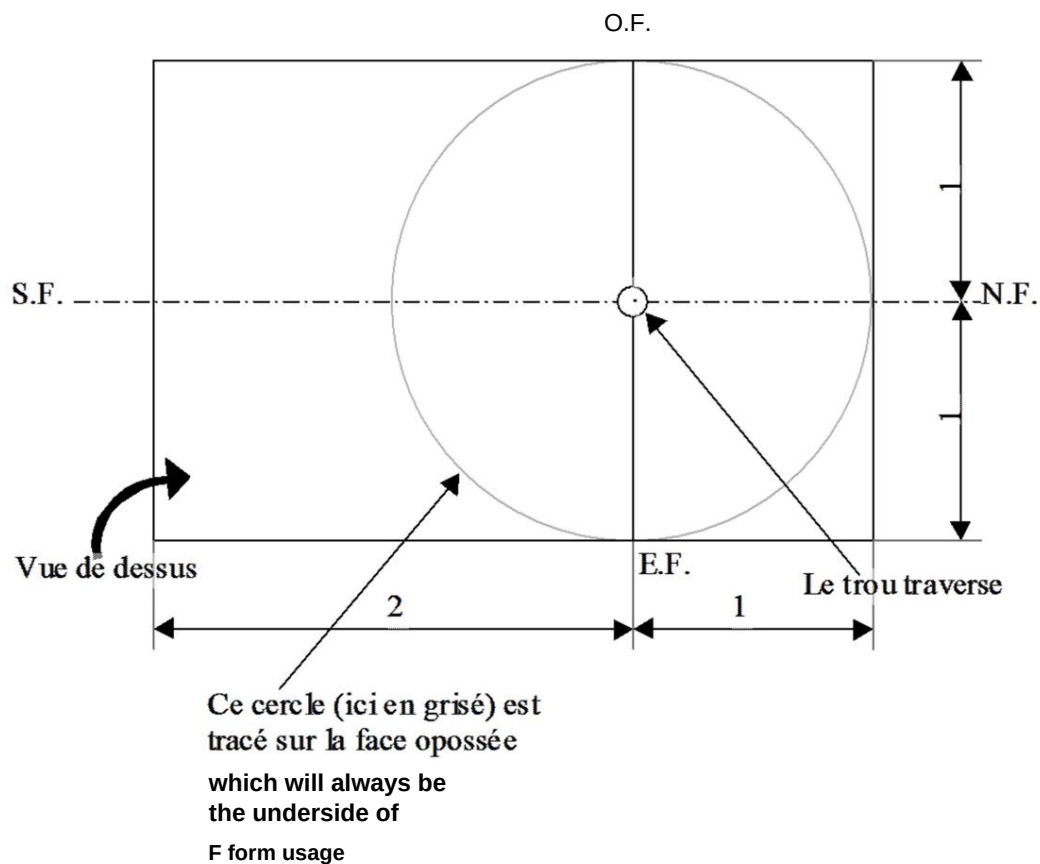

It is necessary to know, and we have just developed that they could not approach this form since their knowledge created in her a state of assurance and sufficiency in approaching any form. They have not understood, felt what a form is, the concept of form escapes them.

- In the case of AIDS, we find that the components of the vital field are no longer perpendicular.

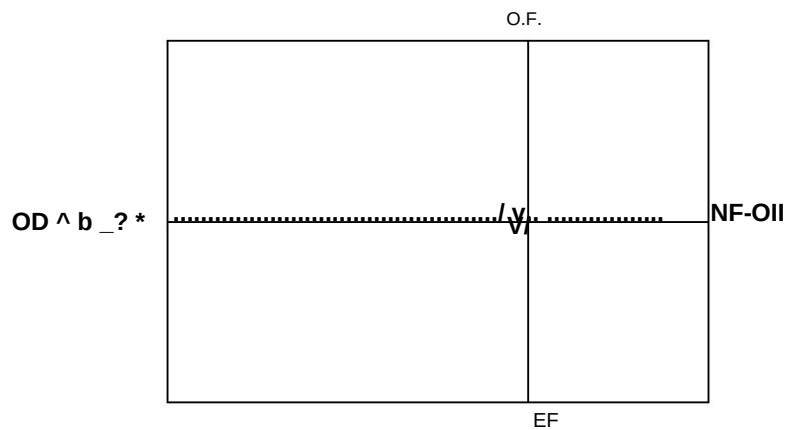

- Very tired, depressed people have a weak vital field - that is, the components are more difficult to detect -.
- For people wearing a motorcycle helmet - which encloses the head - the vital field does not detect more, even with artifice.
- The life node on the left temple is weaker.

Exercise :

Make a wooden plank, parallelepiped of length 2, width 33 thickness of your choice.

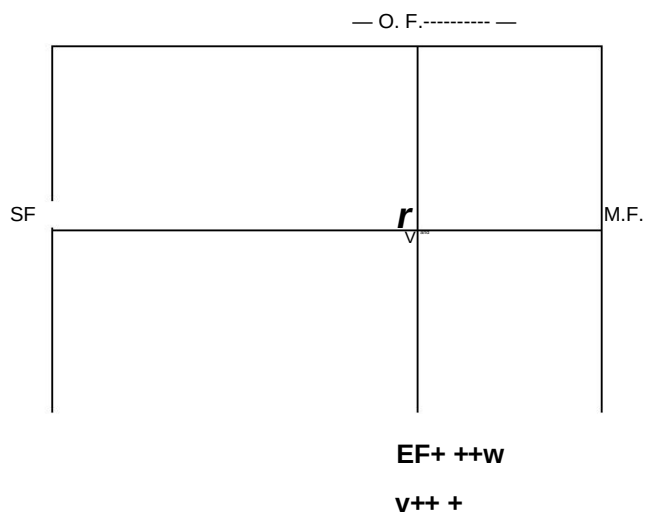

1) Vérifier qu'on ne détecte:

and this on Tax NF, SF

2) Check the polarities

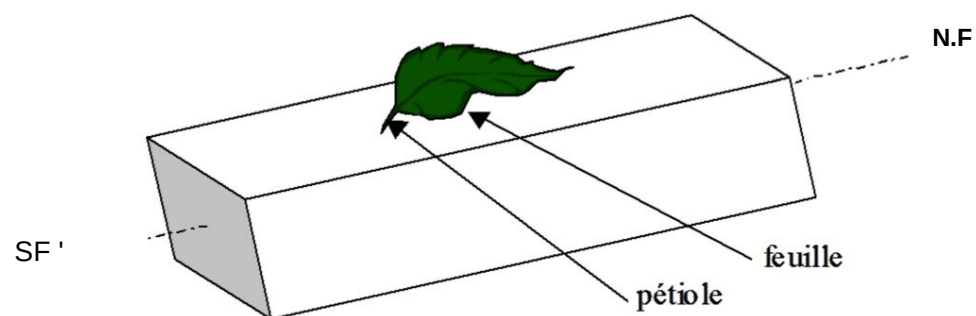

3) Check that a pebble placed in the SF emits the components of the vital field.

Exercise :

We start with a good piece of parallelepipedal wood:

Its axis is placed along N.-F., SF.

We put a freshly picked leaf on this plank following the drawing, the petiole towards the SF

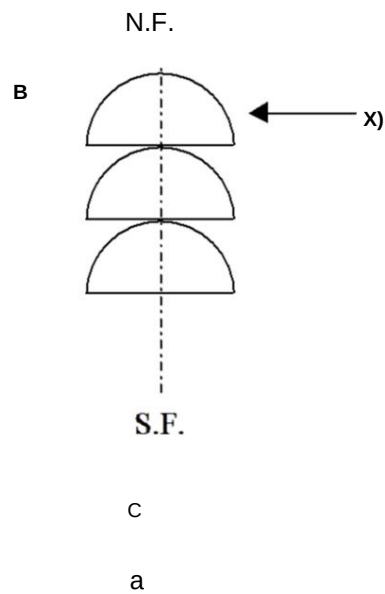

Blood:

- 1) that the life node is detected at the SF.
- 2) the leaf, alone, thus directed, emits the node of life by its petiole.

Exercise :

We set up a battery of full half-spheres, for example 3, whose horizontal axis at NF, SF.

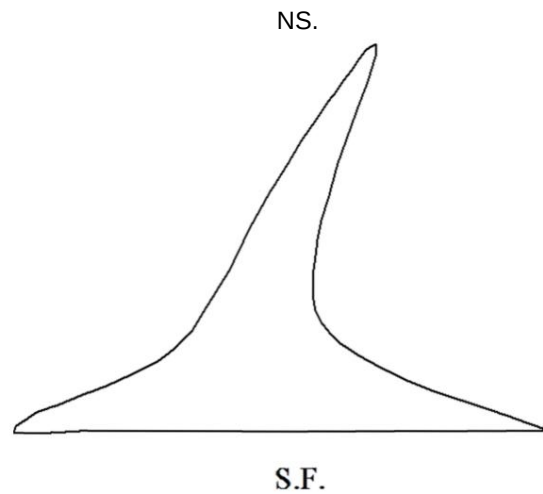

We send the node of life - for example by editing the previous exercise $\ddot{y}$.

- 1) Check that it is detected along AB (see figure above).
- 2) Check that it is detected at SF, i.e. at CD, the life node and V'm•

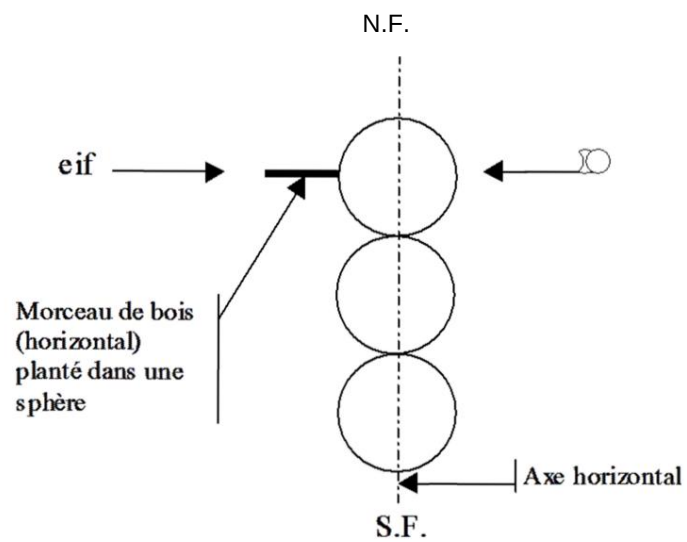

~~Note:~~ The best V'm is ineffective if it is not accompanied by the life node.

Exercise: We reproduce the shape of a rosebush thorn and place it like this:

Show that we detect the knot at the SF.

Exercise: We associate 3 solid wooden spheres according to the assembly below.

We send the life node and an eif according to what is indicated on the diagram.

Show that the life node is detected at the SF.

One night Tchuang-Tseu⁴ dreams that he is a butterfly.

When he wakes up he asks himself:

“Who am I really:

a butterfly which dreams that it is Tchuang-Tseu

Where

Tchuang-Tseu who dreams that he is a butterfly? »

⁴ Tchuang-Tseu or Tchouang-Tseu (IVth or beginning of the 1st century BC).

Chinese Taoist philosopher, successor of Lao Tseu and remarkable writer of the Tcheou period.

His work, the "Tchouang-Tseu", develops with dazzling verve the themes of Taoism - this being the direct, intuitive understanding of life and the global vision of the world; in the same way it goes in the direction of the development of the natural spontaneity of the spirit, (the human self no longer intervenes) - in unique anecdotes, often ridiculing Confucianism then considered artificial and heavy, or deep jokes which might seem, to unprejudiced minds, sparkling paradoxes.

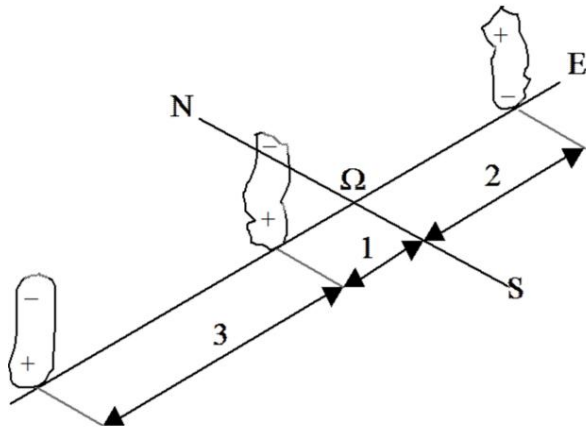

Note: we will see in other chapters the emitting discs and squares and then the node of life goes out with Peif.

III Consequences

- It should not be deduced from this that the living can be described by a vital field. We have moreover since you could impose a vital field on a stone.
- Can we say that every living system has a vital field?
 - We have seen that some sick human beings have an undetectable vital field even by artifice.
 - That an AIDS patient has a completely disturbed vital field.
 - But also we realized by studying the living beings that are in the Valley without Back5 to the Brocéliande forest in Brittany - fish, frogs, birds, trees, multiple grasses - that they did not have a vital field and this some be the artifices. It seems that an operation was set up around 7000 to 8000 years on this region.
- As soon as these animals - and this is the case with birds - leave this region - the Val without Return - they find their vital field.
- It should not be inferred that the Fontaine de Barenton, also in the Forest of Brocéliande has the same properties. It stabilizes, imposes even more the vital field.

Exercise: We take three stones of approximate shapes that we put on the ground the following way:

Suppose we have 2 underground streams at different depths, one oriented North-South, the other East-West.

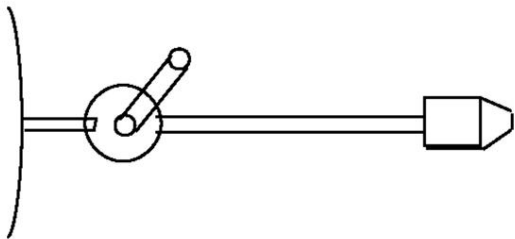

This assembly requires prior knowledge of the polarities of the stones.

Check that, before placing the pebbles, there was detection at Q, which is on the vertical projection on the ground of the intersection of the two water currents, the V'e and the knot of life and that after the disposition of the pebbles, we no longer have V'e•

Check in the same way that if harmful eifs were in a close vicinity, they also disappeared.

Exercise :

We take a chignole; the life node pendulum is placed swinging above.

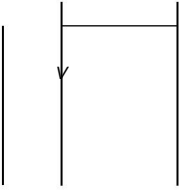

By leaning the chignole against oneself to make it turn, one detects the knot of life at the end of the Forest.

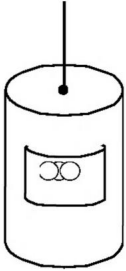

Should we deduce from this that there is a knot of life as soon as there is movement? Absolutely not ! The knot of life, here, appears because it is already on the mechanic.

IV Realization of the pendulums of the vital field

at 2cm ti Mm
 ε

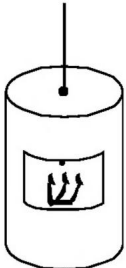

We start with a cylinder in hard plastic material, like those for the polarities.

We glue rectangles of paper on which have been drawn the 4

formes C0 ICO G 01

and also a pendulum with string which crosses on which we stick $\dot{y}$

Conclusion :

The living has not been characterized by the vital field. We found another shape associated with life. It is the fundamental form of the Living.

We will present it in the next chapter.

V Brain Walk

Man has always sought to use natural forms for his benefit and for his pleasure.

To achieve this, he chose "de facto" the existence of a natural order of things which he made party and to which he had to submit. This natural order of which he is a part depends on the chosen representation. It is necessary to soak up the fact that the representations of the world rationality in which we are at the moment - Usual field of coherence⁶ - are not those of the Ancients who were in the Other Field of Coherence (C. of C.).

This intelligent, pre-established order - if we consider the usual C. de C., otherwise it is a cerebral construction if we consider the other C. of C. -, intelligible, and hierarchized is the necessary support for experimental achievements. If we want to continue our study, it we will need, as our ancestors no doubt did, to soak up this order and think this order with structures that adapt to those of this order - it is an approach that is not not in common thought - so as to live in harmony with nature and conserve our both physical and moral health.

Through the study of forms, eifs and all that is associated with them and that we will study even more in the course of the 21st year, we will try to find this order.

For this, as Louis Charpentier says, it is necessary to go back to the "Essence of Things".

⁶ C. de C. for Field of Coherence.

3/5 Knot of Life

That done, on the right side of each square of card stock, we draw parallels to the sides, away from the center of a determined fraction of the half-side.

Check that :

We detect respectively above the center with specialized pendulums

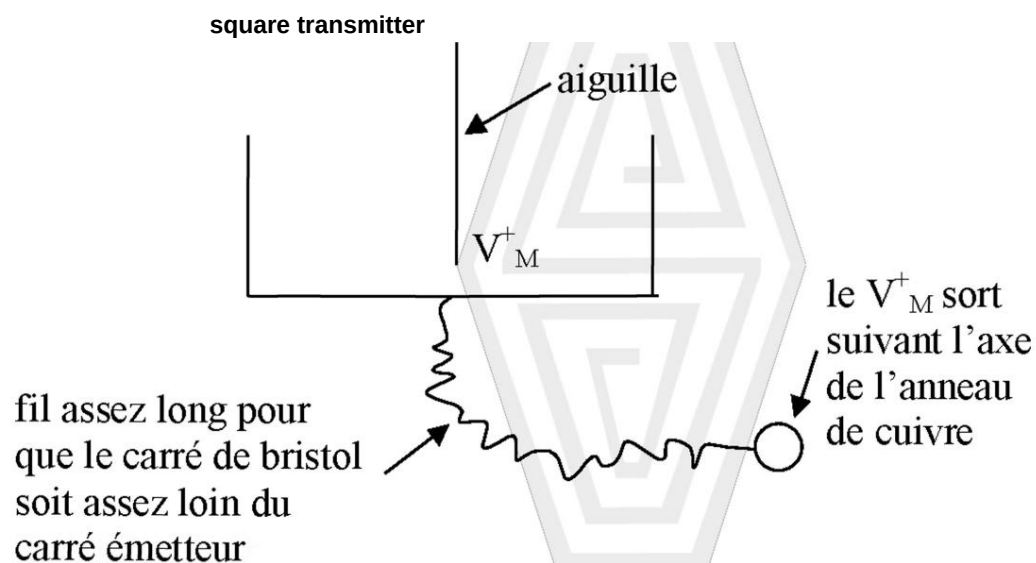

1) Fraction $\frac{3}{5}$: Emission of the Node of Life

2) Fraction $\wedge$: Emission in M of $198^\circ.5$ (on the transmitter disc - Be careful that with the square emitter it would not be the same angular values.

3) Fraction [y] : Emission at E of $108^\circ.5$ (on the transmitter disc)

4) Fraction: $\frac{3}{5}$ Emission of the Skin

5) We put in the center of one or the other square of bristol a form emitting an eif - level EFF
-, for example a $V+m$

We will take a ring of small diameter, approximately that of the hole obtained with the cookie cutter in bristol card.

And we put the card such that its center is confused with the small copper ring.

© EÜREECALL

Show that only the fraction γ will disperse the $V+m$ over a distance disproportionate to the "power" specific to card stock, in the room where one operates.

6) Then check that after a certain time - you have to wait 5 to 10 minutes -, beyond that, as if the electric γ associated with the magnetic 1 was the beginning of a carrying eif field.

7) If we associate γ_{ij} and γ , check that we no longer find $V+m$ around the bristol.

8) If we add γ : to the previous ones, i.e. $j \times$ the VV - called ambient because it is detected in a volume of space in which is the cardboard square - detects itself.

Note: These experiments do not provide access to C. de T.

If we placed in the center of the bristol square a form emitting a C. of T., or the flight of the C. of T., none of what has just been presented in exercise would happen.

Conclusion :

We realized that many past events, forms created in the past - that can go from a few centuries sometimes and often much further - do not deliver their secrets easily and that it is necessary to use artifices to raise the veils; because it is indeed veils. He seems like the past, like what's far out in space - asteroids, meteorites, comets, and much further still - are covered with protection and cannot be approached directly.

Approaching these forms, these events therefore requires a preparatory study which differs following each and everyone.

The study of celestial bodies as presented to us by photographs is of great importance. wealth if we know how to approach these forms.

In addition, the following fact must be taken into account: any study based on the photograph of a form, of a place, uses photography as a support; from this it emerges that it is necessary to place the transfer between photography and form, or photography and place.

. Naturally photography emits eifs, creates states in a same environment much further - but it's not necessarily all that will be detected on the form, the place.

Paper 17

May 98

i. Back to some concepts

A representation is placed in a field of coherence; it can even impose a field of consistency. Thus a definition that is too hasty can lead to a break even in the field of coherence. by extension of a representation in this coherence field [1].[2] [3] .

The usual coherence field obliges each human being to plan, stretch out for communicate with other human beings, the human being "fits in", such is the expression consecrated to society, which is rational. What a human being gains by blending into a society, he loses it in himself; he loses his personal power. It becomes more fragile, because more easily identifiable in this society in which he has melted by identification. An individual, in our rational society, is perfectly identifiable. It is followed from birth to death and this more and more. Electronic systems will continue to improve, credit cards by example, this imprisonment of the individual in the midst of others. We thus obtain a overlocalization compared to the usual localization and this individual in the mass of individuals, overlocalized will lead to breaks in the concepts of crowd, society, already delocalized entities, to relocalize them and these relocalizations will themselves produce overlocalizations. But Overlocalization process can result in localization within the rational coherence field.

It's not so much the act of blending in (within rational society) that is serious, it's the spirit in which the human being merges. He loses the possibility of becoming aware of the concept of field of coherence and is no longer itself because a field of coherence can be more or less in agreement with a living being, especially as this field develops. At first, the launch of the field can be satisfactory but afterwards, impurities appear, especially when it comes to the rational field. He then slips into the field of incoherence that all beings humans, constituting society, wanting to be rational, tries to have people accept as a consistency.

Concepts can belong not to coherence, but to incoherence and these concepts entering a field of coherence pollutes it.

In the point of view developed in this course, a human being does not exist in relation to others, we will say "is not in relation to others", the others are only because he is. However, only the one who is aware of it can talk about it. But we have no right to think of this same position for the others, otherwise we fall back into the usual field of coherence.

© EÜREECALL

In the rational representation, the individual is led to play the game of pseudo-objectivity scientific: that is to say, we want to align the values, compare the results. The nickname objectivity lies in this possibility of constructing multiple scales of comparison, but this is often arbitrary. The RBBs who apply it as much as they can (this is a justification for their behavior and a need to be recognized as a good scientist) extend it to human relations and morality. We arrive at absurdities.

This freedom that the researcher gives himself in his construction and projection of scales of values is a decoy. He thus gives a flexibility to the usual field of coherence and believes that there is a loophole outside of man in a generalization of concepts. The human being is taken in a straitjacket: its usual field of coherence makes it a prisoner. The notion of freedom is brought to make him forget this straitjacket, freedom is a dilution.

This freedom (and at that moment, we don't have to talk about it anymore because it is implicitly understood) is in another field of coherence, this one in which the being projects itself at the same time as it puts inside. This last concept belongs to another field of coherence, but then the field of rational coherence can be rethought from this other field; little by little the notion of field of coherence becomes a little clearer, still without being defined, the usual field being by construction the negation of the field of coherence since it considers itself universal, wanting to explain the universe it enables to discover, whereas with the other field the obs becomes aware that it discovers, creates because he launches and gets into it at the same time. This replaces the "Know thyself same" from the temple of Delphi; moreover thought which is continued by "And you will know the Universe and the gods".

The being then knows that he is the alpha and the omega.

In most works dealing with non-Orthodox subjects, reference is often made to being human who is the alpha and the omega; the meaning is given: beginning and end. This is intended a deeper explanation than that which is usually given, because it blocks, for the reader, any search for deeper sensation. If we think of the field of coherence that we launch and in which one places oneself, the alpha is generated by the omega in which it is; alpha and omega are in dynamic duality in the sense of creation and containment.

In Eastern philosophies, reference is made to "the truth which is in itself". The translations and understandings of this expression are generally wrong and perhaps the authors, themselves, expressed in words what they felt without worrying too much about whether others

© EÜREECALL

interpretations, more or less erroneous, were possible. In any case, when we look at texts dealing with these questions, you have to put yourself in the state of mind that you have to take when reading or saying a proverb (proverbs expressing popular common sense); that is to say, at the same time as one assimilates the saying, the proverb, one must discover its way of understanding¹. Likewise, the reading of these booklets proceeds from this principle.

The form is fundamental in the approach of the global because it emerges or immerses itself in space time but also, it is the way. At the same time as the model is set up, the representations, we must follow the spirit in its approach. You need the object (the model) and the image (the way). From the image we draw the necessary discipline of mind when we leave the field of coherence usual, discipline which in this case is implicitly understood, so as not to fall into phantasmagoria, these perhaps not always belonging to the domain of the absurd (the most often they belong there).

Rational thinking has eliminated fear of the demands of multiple gods and the superstitions.

Indeed, the human being having these entities in his representation and knowing them badly, arrived at their ascribe multiple powers and submit to many whims he fabricated from delicate or desperate earthly situations. These representations constructed in atmospheres of superstition were sometimes operative. They corresponded, in a model, to neighborhoods of comprehension susceptible of a certain operativity. Many wizards must have used these processes.

The gods did not belong to the realm of the absurd. We had to find their coherence in a coherence field.

We will distinguish between local and global; the local emerges from the global or is immersed in the global by what we call with B. Vivès the decalaires. But there is also the other concept created by Frank Ravatin: the canal. We saw decalaire and canal.

Let us point out that local and global are not exactly tonal and nagual of the Yaqui sorcerer, Don Juan, quoted by Castañeda in his works [5]. The tonal is the protective attitude that an observer keeps

12

1 This is also the way to read Jacques Breyer's book: "Terre Omega" [4], Reading leads the way (in a more concise form and which gives the example of such a sensation: the voice , this is the way!).

2 The term immersion was chosen by Marc Beigbeder (private communication).

© EUREECALL

ahead of the global. It's not the local; it is the serenity of belief in the stability of the local to the moment we look at it, appreciate it, judge it, have the impression of living in it. But this serenity is put by Don Juan outside the observer. It is almost a property, a state of local with respect to the observer; you have to represent it as such in order to feel it as a state in surface and interior, the tonal.

The nagual then is understood as a state of relocation. The observer does what he wants a witness, and puts this witness either in its representation or attaches to it its witness characteristics and relocates. The nagual is the state of all these operations. This is why Don Juan says that the nagual is creativity.

Let's go back to the local and evolve a bit.

When we speak of local, we must understand that it is an echo of our usual field of coherence which is launched by the observer, but we could have *other "local"*. In a field of coherence, if the space-time structure is present, a local is the echo but to a local does not correspond to a consistency field such that the correspondence is one-to-one. From the moment when another field of coherence intervenes which is distinguished by the instability of the landmarks, several representations of the room are possible.

The tonal of which Castañeda speaks is therefore a state of the habitual local in relation to the human being. observer, but it is also a state of the human being in front of the local, that of the "warrior impeccable" as Don Juan says but which the human being attributes to the local.

In reality, these two states are in tension.

On the other hand, in what is presented in this work, there is no separation into *objective* and *subjective*. Just the fact of thinking objectively and subjectively prevents one from having access to another representation, another coherence. We break the Other C. of C. to fall into the usual room.

We insist on the following point: the Universe is not given a priori and the human being plunges inside. We must understand the Universe as an echo to a field of coherence launched by the observer; the human being launches his field of coherence at the same time as he puts himself inside (this which cannot be conceptualized in the world of rational thought). Existence depends before all of a field of coherence.

On the other hand, the forms are not immersed in the space-time structure; they are also fundamental by this structure; they emerge from it and more or less immerse themselves in it and do so

that they will be more or less present or more or less absent is manifested by the Eifs and the Taofel fields.

The ancients used another way of thinking, which we now express by saying that they projected another field of coherence. This is the reason why their constructions and objects often seem incomprehensible to us and we classify these objects in the range of objects aesthetic or trivial.

The RBB only understands technical objects (object whose functionalities are located). J. Ravatin had, as a teenager, sensed that the Ancients had another representation of the world and then he developed his idea into what he named: Non-Cartesian Systems. In a non-Cartesian system, the functionalities are no longer characterized by the form, the nature and location of the part in the system. Features are outsourced. Such apparatus, in which certain functionalities are delocalized, is said to be a "Phenist object" ³ 4. An object phenist can even have its components (its components are not subsystems of the object considered as a system) localized, the greater part of the object escapes us, is not visible to us because it is delocalized. This is the case of perpetual motion machines which have been treated with derision by the scientific world: if we are faced with a Cartesian system, indeed the perpetual movement is impossible as well as it is of the first kind: that is, to get work out of nothing (which is in contradiction with the principle of conservation of energy) or whether it is of the second kind: homogeneity does not break by itself (which is contradicts the second law of thermodynamics). But if we are in front of a non-Cartesian system, of a Phenist object, perpetual motion becomes possible.

To describe the object, its different components is not enough to ensure that we have the entire system and on the other hand, to decompose it by thought into what are called its components does not mean all that one describes the same object.

3 Functionality: characterized by the shape, nature and location of the part in the technical object (Gilbert Simondon, private communication).

4 Thus we are faced with three classes of objects:

- Technical objects with all localized functionalities.
- Aesthetic objects for which the functionalities are non-existent, s -
- Phenist objects of which one or more functionalities are delocalized A

technical object can thus be an aesthetic object, in the same way a Phenist object can be an aesthetic object. But when we go from technical or phenist to aesthetic, we change coherence. In the first case we remain in the usual coherence field, in the second case we change the coherence field.

The Phenist object totally escapes this type of approach. From the moment when functionalities are delocalized, the shape that appears is not enough to describe the system. It is an implicit postulate of the rational way of thinking to believe that by describing a system or its components, we really have the components. On the other hand, in the case of the object Phenist, the principle of conservation of energy and the second principle of thermodynamics can no longer apply: the one and the other are two different views of another principle that we could call "Principle of Location".

The field of rational coherence develops, throwing into it scales of units: units of length, time, mass, force, intensity, voltage, flux etc. Consider the unit of time that we launch into the past: this allows, in the field of coherence, to date men prehistoric from the moment we posed the problems: the ancestors of man, the origin of man. Various types of prehistoric man have been successively found and here clearly appears the concept of existence in a field of coherence.

It must be understood that having become aware only through rational thought, by launching the time scale in the past, we manage to date (but this is not the most fundamental).

By dating we realize that everything happens as a creation, which is totally different from the usual point of view. Thus, going up the time scale in the past (the unit being the millennium), we manage to recreate in a given field of coherence, here the usual C. of C.; but thanks awareness of another C. de C. (Looking at the usual C. de C. allows you to discover the instabilities of this C. de C. and to realize that we create rather than discover.

We nourish by this process the other C. of C. and also by the fact that we become aware that the thought rational is a C. of C.) we create in the usual C. of C. the ancestors and the origins of man.

. The origins are localized as one traverses the scale. Hence knowing this effect, by applying it differently, other origins become possible. The great religions are the trace in our local world of another C. de C., they express other origins.

The usual C. de C. can become unstable when you throw unit scales at it. But he is unstable than for those who are aware of the concept of C. de C., therefore who is in another C. de C. In the usual C. de C., we force the world to be "fixed" because we think we are observers of the world. In adopting the other C. of C., one is no longer an observer in the rational sense: one projects and one puts oneself at the

times and then there are privileged positions for the observer, taken in the new sense of the word, thanks to which the room will deform. The C. of C. underpins worldviews. The elders knew all this but in other forms. Maybe they didn't have their C language.

of C. In our civilization we have the language of the rational C. of C., it is what makes the force of this one compared to others which preceded it: on the other hand knowledge is not any more the privilege of a caste but everyone can access it.

The usual C. of C. language was quite easy to establish because it uses minimal effort to convey an idea; there, the Cartesian character is present, and our principle of the minimum of energy is the very expression of the usual C. de C. language.

II. The Creation of the Past in the Future

A myth that was very often evoked, and which is still as much is that of Atlantis. All indices of its existence in our C. of C. are the creation in our time scale of the continent and Atlantis history.

Plato spoke of Atlantis in his two famous dialogues: the "Timaeus" and the "Critias". We will not return to these texts, they are sufficiently well known; many books have cited them and reproduced passages from it. Atlantis, on the other hand, has been located in multiple places. Is Plato's story symbolic? Or is it a legend? Or a caption that embellishes older events?

In "Timeah" and "Critias," the author attributes to Socrates' account what the priests of Sais told Solon, legislator of ancient Hellas, who traveled to Egypt around 560 BC Jesus Christ. The assembly of the priests of the goddess Neitle of Sais, protector of sciences, would have revealed to Solon that in records, which dated back millions of years, it was mentioned the existence of a huge island the size of a continent, located beyond the Pillars of Hercules and engulfed by the waters after a sudden disaster. - This can be thought of as the expression of a story but also we can create and "aspirate" this story.-

In the course of this same story, Solon learned from the priests of Sais of the existence in Athens of a State which, having been attacked by the kings of Atlantis, had victoriously repelled these invaders. Corn, shortly after, an unforeseen and brutal disaster engulfed the island in the waves.

© EÜRECALL

This dialogue from the *Timaeus*, in which the plot of the history of Atlantis appears, also touches on astronomy, the science of numbers, musical harmony, philosophy, religion. This is how we can locate this engulfment of the island-continent approximately -12,000 years from us.

The second dialogue, "the *Critias*" focuses on the general and physical geography of Atlantis. Plato relates that in the center was a fertile plain protected from the northern winds by high mountains. The climate there was more than tropical and the inhabitants could harvest two crops a year.

This second dialogue mentions the details relating to the capital: buildings built in red stones, white, black; large temple dedicated to Cleito and Poseidon, decorated with gold ornaments, walls covered with silver, a golden enclosure which surrounded the temple near which, at various eras, the ten kings of Atlantis in order to proceed to the sacrifice of the sacred bull, previously captured by means of a net⁵.

Of course, we can say that it was Atlantis that influenced Europe, Asia and even America and this has often been invoked! But this remains a rational explanation, from C. de C. usual.

In addition, trades, industry, science flourished in Atlantis; there were many ports, canals and worksites. The commercial relationships mentioned with the outside world affirm the maritime vocation of Atlantis and suggest to us the use of boats capable of crossing the ocean. The 1,200,000 men in the army, a considerable number, oblige us to admit the existence of a high population - if we stick to the usual point of view -.

Plato did not make the mistake of confusing Atlantis with the Americas: "Another continent was west of Atlantis. It speaks of the ocean beyond the Pillars of Hercules (the current Strait of Gibraltar) and says that the Mediterranean is only a port... It is in this Atlantic Ocean that he places an island-continent larger than Libya and Asia Minor combined.

Very lively discussions have taken place about these stories. They originated from a article published in the "Mercure de France" by Professor Couissin which tended to prove the mythical character and lack of scientific basis on which rests the hypothesis of the existence of Atlantis, this article claiming that it was, in fact, only a hoax. For the archaeologists, the existence in the past of a link between the "Old World" and the "New

⁵ We find the sacrifice of the bull, the rites and ceremonies dedicated to the cult of Mythra widespread in Europe and Asia.

World", would provide an explanation for an irritating enigma: namely the astonishing analogies that can be discovered between the Egyptian and pre-Columbian civilizations, that is, say rites, adoration of the Sun, pyramids, use of a ternary symbolism. But these resemblances do not hold, let us point this out immediately, if we assume that these civilizations drew on the same source which is in the process of being primed by the emissions due to the forms. On the other hand the ternary symbolism is also found in China and also each time an archaeologist a little versed in the occult approached an ancient civilization.

The search for the position of Atlantis has given rise to countless possibilities. The commentators faithful to Plato's account support, for their part, the position of Atlantis in the Atlantic Ocean and more precisely the Canaries and the Azores would be emerged vestiges but on these islands there remains no trace of Atlantis; they are still quite small. So that others locate it in the most diverse regions, Greenland, Ireland, the island of Heligoland, the Atlas, Mongolia etc.

Other rather singular thesis: Atlantis would be the moon torn from the depths of the Pacific. He is curious that the authors of this idea did not compare the radius of the moon to the deepest depth large Pacific which is about 10 km.

It can be retorted that Rudolph Steiner assumed that the moon was born of the earth and some followers of the creator of Anthroposophy support this idea without thinking. It must be said that R. Steiner, in his visions, might have come to such a conclusion, but this should not be taken as a scientific truth but as a means to reach other conclusions which are useful.

Master Philippe de Lyon had also seen, by doubling, multiplicities of suns behind our sun... likewise, he gave quick visions to people who asked him questions: it could only be of a symbolic nature or even of the kind of unimportant vision, usable perhaps (because it had been given at a given time), in an astrological chart or something else [7].

Likewise Edgar Cayce and many others. Similarly, the interpretations of clairvoyances such as those of Catherine Emerich and others, where dates of events are given. These dates do not not put in the schedule; they are the clue that the event to come could be datable.

The hypothesis of Atlantis submerged in the Atlantic Ocean brings together the greatest number of votes. In France, two men of Science attached their names to this thesis: Pierre

Temier, permanent secretary of the Academy of Sciences and Louis Germain, assistant at the Museum of Natural History [8].

The study of the bottoms of this ocean shows, in fact, that at a certain time, the shores both on the side American than European and African were much more advanced in the sea, while there exists, in the center, an underwater plateau, the depth of which does not exceed 900 m. constituted by the Azores.

Pierre Temier gave a lecture at the Oceanographic Institute in 1913 in which he supported this thesis.

Vulcanologists are against this thesis. They claim that the continental plates, by their positions and structures, do not at all allow us to affirm the existence of the famous continent engulfed. And we arrive at the hypothesis of the explorer Rebikoff who, through his underwater dives, been led to believe that some pieces of Atlantis would be near the Bahamas, which Edgar Cayce had also seen clairvoyance. Rebikoff settled in Florida and proceeded, aboard a small seaplane, reconnaissance with a view to finding submerged sites (this technique has been developed in the Mediterranean and yielded surprising successes). He flew over bodies of water in the Bahamas archipelago and the appearance of a simple geometric shape, thanks to the transparency of water, hit Rebikoff: in one case a room, in another a 550-meter-long gutter, lined with walls hewn out of the rock.

Testimonies brought back by divers like Pierre Camac mention enormous walls, for example those of the island of Bimini, oriented northeast, extending over several hundred meters in length: they are made up of blocks of 5m x 5m and 50 cm in height. The weight of each block is 25 tons. These blocks are bound by a dry cement, which suggests that these blocks were assembled on dry land. Techniques and materials can come close to what has been observed in ancient Mexican temples. The dating is difficult to establish. She has been estimated at -4000 years. The remains would therefore predate the civilization of the Olmecs, a of the oldest known from pre-Columbian Mexico [9].

But a curious fact was reported to Pierre Carnac: the fishermen of these waters had never seen these submerged constructions before their recent discovery by divers. Of course there is had the views from the plane, but others, as P. Camac has confirmed, can be distinguished by simple boat trip in calm weather. It therefore seems that these walls are localized.

Our classic notion of existence is based on the past, the present, the future. time is seen like the number line, even topologically.

But time can have what we have called **cumulaires⁶** or **decalaires⁶**, either linked to Pobs, either related to certain observers (i.e. for an epoch a cumulative would exist in the past but not for another time). In paleontology, the theory of evolution is placed on the usual time scale. In Paleontology we begin to sense discontinuities there.

These are only the index of an imperfection of the system of projection of the time scale.

Remarks :

- 1) The decalar only exists because a neighborhood has been created; we set up the decalaire which makes move from global to local and vice versa.
- 2) This representation makes up for our impossibility of immediately observing the global and on the other hand, that in our localization error, we create an operative representation. The human being, even from error, must always derive a truth (truth on his own scale). It's here redemptive death in life. It is the manipulation of archetypes for those who do not have understood. It is the stopping of the race and the sublimation of those who want to be gods. It's here dilution in the solvent which will become a decalaire. It is homeopathy at the level of form. It is the disappearance of the level in favor of plenitude. It is the outside of concepts.
- 3) We must not forget the privileged position of obs. Obs is the origin of landmarks.
- 4) In a book by HP Lovecraft and A. Derleth [10] we find this: "We must to congratulate, full of gratitude, that the human spirit is incapable of establishing relations between the various elements of the Universe. We live on an island of ignorance, among black people oceans of infinity, where it is not given to us to venture very far..."
- 5) The arrangement of the more or less localized forms of the Local plunges us back into the delocalization. All these delocalizations, starting from the more or less localized, constitute leaks from the Local to the Global. These are the ones that are most easily accessible to us.

⁶ Cumular: term coined by J. Ravatin (see previous booklets).

Décalaire: term coined by B. Vivès (see previous booklets).

Reminder: These concepts were developed by these two researchers around the years 1963-64. They didn't know each other. Initially cumulative and decalar had about the same meaning too, when these two researchers got to know each other and exchanged their results, they decided to keep to decalaire the first meaning given by B. Vivès and to cumulative, the meaning of flight. markers but followed by a new catch-up of these markers. Note that the definition of decalaire for B. Vivès was purely mathematical. This was taken up by Ravatin in a more physical context and slightly different in meaning from what Vivès had axiomatized.

By making this hypothesis, are we not assuming that we can judge without any notion of time ? Do we not place ourselves as a privileged observer in relation to a possible observer? If we Considering it this way, we arrive at Dunne's "serial time" [11]. It is a recursive process. Onne will not stick to this point of view because it is absolutely artificial and this tendency to build the observer of the observer etc. indefinitely, is not a correct observation of oneself but an illusion that brings us back to judging step by step, therefore to being unable to escape the location. Any process which involves the infinity of numeration or which is in One-to-one correspondence does not correspond to a correct process. Nature does not proceed so. One can, to describe the rupture or the evolution of a phenomenon, choose a model which does not not copy reality point by point, but you have to be wary of the model in which you introduce a method which imposes the usual C. of C.. We will endeavor to present a new notion called

*Creation of the Past in the Future*⁷.

We must not forget the privileged position of the observer. The observer is the origin of landmarks⁸. He launches his markers and these, in a given C. of C., generate a reality because there is consistency.

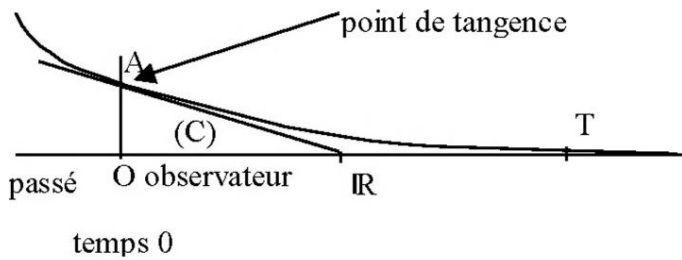

Thus all the indices of Atlantis, the texts of Plato and all that followed from Plato to our time, cause Atlantis to appear and, when it will be there (will have been found one would say in the rational C. de C.), one will find in it all the clues of its disappearance there is - 12000 years approximately. This process enriches the room. Edgar Cayce described Atlantis in a more or less folkloric way in his "readings".

Thus another existence is profiled which will come to converge towards the usual existence, the latter performed on the number line.

⁷ Notion devised by J. Ravatin. Let's complete this paragraph by adding that the notion of infinity applied in physics imposes localization. A model is not forced to follow a phenomenon step by step, but certain parts of a model entail a C. de C.. S. Luspaco introduces the transfin in place of infinity, which corresponds to it at the physical intuition of infinity.

⁸ This point of view should not be opposed to that of relativity. In relativity, the observer corresponds to the point of view of the physicist. The notion of consistency is not considered.

© EÜRECALL

This diagram should be understood as follows: the straight line IR is that of the flow of time following the point usual view. The curve (C) only has meaning for the observer O who is the origin of the scale of time he projects into the past.

When Edgar Cayce was, by his doublings, observer, he saw because he placed himself in A intersection of the vertical in O and the curve (C) and the tangent in A intersecting the line IR in T him overlooked the O IR axis, the spawn point of Atlantis (on the time scale). So, he saw the reappearance of Atlantis in T but for him, it had disappeared -12,000 years ago because it participated, without knowing it, in its relocation. The date at T was only valid for him because the curve (C) was his.

This curve has no origin; it is constructed by the observer O⁹. In reality there is only one point A and a straight line AT which gives approximately, for O, by accumulation of proofs of a past existence (but which never took place) a creation on IR around T.

What has been said for Atlantis is also true for the Mu continent mentioned by Churchward [12].

In the creation of the Past in the Future, what becomes of the events attached to what we usually names (and this in a relative way) the near past? Take the case of his parents, grandparents, great-grandparents^{10 11}, those we have known and who have disappeared, those whom we have not known but of whom we have heard because their relatives have known them.

This is where the immersion of stabilization takes place; that is to say that, in this near past, we have a kind of extension of the notion of present (and the absolute present is felt only by the past close)¹¹.

⁹ She emerges from a decalare.

¹⁰ To all of them, they constitute a channel.

¹¹ The notions of near past and absolute cannot be defined separately. The absolute present is felt as a limit of a period of time. The advantage of talking about the recent past is that there is no fixed limit; it is a feeling.

© EUREECALL

Time is counted down through a recursive process. We perceive two notions at the same time: that we live and what we project (here the time scale) and the scale has as its origin the moment lived. This is how they are connected.

But you have to reflect on yourself and ask yourself what you are thinking when you accept the point of usual view. These supposedly recursive systems carry with them their own destruction. Is it due to the nature which refuses recurrence, or to our intellect which itself breaks its model? Both answers are not both positive and negative, or mutually exclusive, they are in dynamic duality.

We have seen that in paleontology, we launched a time scale: - 10,000 years, - 20,000 years, ... 100,000 years, ..., - 500,000 years, - 1,000,000 years... We arrive at - 2,000,000 years and this for find the origins of man. We find skeletons of human beings "more and more old ". The first skeletons found in the 14th century were - 30,000 years old; now we are at - 2,200,000 years!

The cumulative is a flight of benchmarks followed by a resumption of stability of these benchmarks; like the decalaires, they are definitive leaks. In these cumulative localizations can be done, which will be stable in general. Thus one creates the image of the past thanks to the past¹². In paleontology, we passes from one human type to another older human type (which will be defined a priori or during research) and we go back in time thanks to the time scale. These two combined scales: that of the human type applied to that of time will give the creation of the past in the past, discover the origins of man, his way of evolution. In the usual C. of C. the observer does not have absolutely unaware of its privileged role of origin, launch of scales,

¹² This process is not recursive; that is to say that the creation of the past thanks to the past is not done by the past. So let's say that:

Any recursive system is to be rejected but its use is operative in the sense that it creates what we are looking for.

We find ourselves, in Paleontology, in front of a creation of the past in the past.

Scales are attached to shapes; they are not separable from forms. The number is intimately linked to the form, "the number is the form" said Anaxagoras.

The human being is a form, the living beings are forms and the time scale associated with them will be more or less compatible; it will bring out certain beings who will be an image of the abstract human-being entity with modern man as its origin and a localized vicinity of man - 2,000 years to - 5,000 years (but without precise limit).

This vision is inseparable from scale and is not separable from past, present, or future discoveries about the human race. Nor can it be said that this neighborhood carries everything within itself; It is a facet of a notion that cannot be represented to us.

superposition by plating of 2 scales, of neighborhood, and especially of eumulary. Thinking in the other C. de C., we see that the overly simplistic and inadequate models of the rational approach are trapped by nature which returns what we are looking for as long as it is consistent with the rational (but this is understood only from the moment one possesses the concept of C. of C.). This action in the rational (i.e. to create the extension of the model, at the level of the neighborhood, planned in the model by applying the model to reality), applying the human representation, its swelling until it can no longer be accepted by the real, causes the cumulative to burst; a new older skeleton appears and so on.

We should not ask the questions: "what if we had not dug at such a time, at such a place?" », or, "Was the skeleton there before we dug?" ". These questions have no no Sens. It's absurd. The absurd is not the equivalent of negation. There is the yes, the no and the absurd. To create indeterminacy between yes and no, or even to manufacture Logics with discrete or continuous values (like some works carried out by Poles in Logic mathematics) does not include this third possibility which is the absurd. Gerard Shoemaker understood this very well when he preached in his conferences (started in 1933-1934 and carried out until his death in 1972) a logic with three values: the yes - the no - and the third that he called the "damn". In reality this "damn" is the absurd. The human being carries the absurd within him. It's here that the Judeo-Christian religion put the entity Satan, which can also be a state. The usual C. of C. does not does not correspond to the absurd but it can lead to it because its strength is also its fragility.

Let us point out that mathematical logic considers this third term as an abuse of language and takes care of screening but there has almost never been formulated an axiomatic in physics making account of such a view of the physical world.

We are faced with the partial acceptance of a model or models placed, by the mind, on the Nature. This model allows us to bring out another vision of Nature, even if it is not correctly understood and it is here that we will say that the model is operative. Nature is not mute in front of the interrogation: it is active (this is the usual representation substituted here for our new representation that makes us express ourselves in this way).

In the classical point of view, the discovery is reduced to discovering and placing in the scale of time. In the other point of view, it is the scale of time which launched has created what we find: the discovery leads to an emergence due to the acceptance by the Universe of a time scale, as it can lead to the emergence of the operability of a device and when this operability has

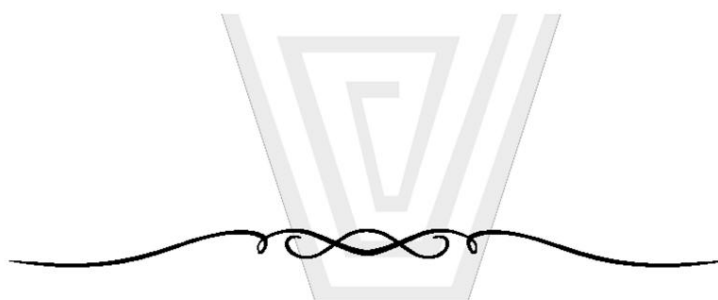

taken place, it can be resumed as many times as you want, as when the skeleton of a type of prehistoric man has located himself, he is there for everyone.

We are faced with 2 concepts: a present and one of its neighborhoods and a time scale; and it is classically assumed that this neighborhood can be arbitrary and that one can construct such neighborhoods that may contain the time scale. This is precisely where the shoe pinches. One neighborhood used to generate a ladder cannot swell disproportionately until it encloses this scale.

From the moment when we suppose the recurrence to be unstable, that is to say possessing within it its own destruction, we cannot therefore pass from a near past to a too distant past. A time scale isomorphic and homeomorphic to the right of the real numbers is not correct but its false character will be operational and allow to bring out entities which will more or less be placed on this law.

Hence these skeletons found, old by our arithmetic, about 1 million years, are creations-responses to our usual counting mode.

This time scale is creative as can be a technical object repeated to a large number copies because from the number (not fixed) comes a new entity, not localized, which can in some cases localize themselves. This number (not fixed) is not a number but cumulative or a shift. The concept of being-human-supposed-to-have-had-an-origin, and therefore similar to us (we admit slight differences and by continuity in time one arrives at very strong differences) constitutes an origin and a neighborhood thanks to which we can launch a ladder that will generate a type of representation¹³.

“The true passion of the 21st century It

¹³ It should not be deduced from this that the process will repeat itself ad infinitum.

© EUKEECALL

it is bondage. »

Albert Camus

Albert Camus 1913-1960, born in Mondovi (Algeria) French writer whose work meticulously depicts, in all its aspects, the absurdity of the human condition to which it opposes the revolt which presents itself as a will for every man to fight without a truce against the inhumanity of its transient situation in the world and to push its anguishing limit.

He was awarded the Nobel Prize for Literature in 1957.

Exercise :

Let's take a sharpened pencil.

1) Check that, placed on a table, it emits through the tip the eif- at the EFF level - resulting from its orientation. This eif is in the aura spectrum.

2) A naturally polarized plywood disk is placed flat on a horizontal table.

a) Check that a sharpened pencil, oriented along a diameter of the disc and which slides along the diameter causes the SF to emit.

- when the point is flush with the perimeter of the circle, the eif of the tree trunk, for example in IR

- when the point is between the radius R and $\tilde{y}^3R$, we only have polarities at SF but no eifs.

- 3 when the tip is between $\tilde{y}^3R$ and $\tilde{y}^jR$, an eif of the aura is observed at SF

- when the point between $\tilde{y}^3R$ and the center of the disc, we find the eif of the spectrum undifferentiated, for example as at the beginning, the IR.

b) Verify that by placing a ring flat on the disk, the center of the ring will detect this which made the SF emit the montage with the pencil.

The ring, on its axis, emits the node of life.

c) Check that by placing a needle in the center of the disc - which is always pierced right through part - and whose extremity is directed at a right angle, therefore following the vertical and downwards, depending on its length, the eif it causes is one of those above.

Consequence: The searches are equivalent to the internal exploration of the tree trunk.

It might be interesting to repeat them on a freshly felled tree stump.

Remarks :__

1) A monument, an arrangement of space, any object whatsoever must behave, if possible, like a living being who has believed, starting from an initial point, from a germ, following certain laws and not in chaos.

At the EFF level - if we leave it at that - we must take into account already known factors which may be used for the development of the plan, but also for verifications of the conformity of the plan with a field that could be called "equilibrium".

We can not be interested in the EFF level and approach the C. de T. and their escape, then what we have sometimes mentioned - but which is not yet treated - the eifs such as VC, FV etc.

Let's see an exercise:

Exercise :

We start from the circular plate, emitter of the eifs at the EFF level, eifs of the undifferentiated spectra and differentiated.

Grooves are engraved along the radii at $198^{\circ}.5$ and $108^{\circ}.5$. We insert into these grooves at from the center of the disc - we will be very careful not to block the central hole - wires of copper, quite short, one end of which begins at the center of the disc.

Check that whatever the position of the needle, nothing is detected at V+m but that detects C. de T. around and above the plate.

2) Directed electric or magnetic fields emit eifs according to their orientation.

Contrary to what one might think the positions of the needle on the transmitter plate circular at $198^{\circ}.5$ and $108^{\circ}.5$ do not allow specific eifs to be emitted from these fields, i.e. the eif emitted at $198^{\circ}.5$ does not correspond to the eif of a magnetic field and that at $108^{\circ}.5$, the eif of an electric field. The perpendicular of these 2 positions has nothing to do with that of the E and M fields of electromagnetism.

3) The circular platter eifs at $198^{\circ}.5$ and $108^{\circ}.5$ are not perpendicular on the square emitter presented in the 11th level course.

Chapter XIII

1-Feedback on concepts already considered

We have seen in the case of the pyramid of Cheops that the Ancients should not have represented it as we see it now from the fact that they thought otherwise and had access to notions which have disappeared in the usual C. of C..

This is why we created the concept of EXT of the pyramid of Cheops, EXT of a form.

The ext is completely relocated; it is linked to the global.

We had left as an exercise the task of showing exts to certain shapes, for example cube, ball that is pierced or on which fine rods are fixed; the holes should be small diameters in relation to the volumes considered.

A crystal always has an ext.

A living being - plant, animal, human being - always has an ext; if he doesn't have one, he is sick.

A human being who is born without an ext - this rarely happens - tends to live as a parasite on the people around him. It needs a neighborhood and it will cling to a presence of this neighborhood: curiously, a human being who is born without ext and who is moreover of weak intelligence, will succeed in being accepted by blinding those around him, to get help, adoption and at the detriment of those who will take care of him all his life.

These cases are usually detected by doctors - they don't interpret it that way at all, but he can't do much. Psychiatrists sometimes try to intervene, but they only move the anomaly, that is to say that the patient seems to have evolved a little while he keeps his parasitic attitude. Any attempts using forms to give the patient eifs and to remove the harmful state (in the eif sense) in which it is, are also unsuccessful.

© EÜREECALL

We have also seen the concepts of primer and progenitor in the case of open forms where they were presented.

Many forms have progenitors.

Ext and spawner are quite different.

A human being may not have an ext but he has a parent - who is not in general the one or the one who begot him -.

Consider two miscible or immiscible liquids.

You can give an ext to the mixture even if none of the starting liquids has one, from a volume V_1 of the first and a volume V_2 of the second.

A liquid can take an ext after having immersed in it a suitably chosen solid, or after have been illuminated by electromagnetic radiation of precise wavelength and frequency, or after driving through a specially shaped pipe.

An oil, regardless of the container that contains it, has no ext, but has a parent.

We managed, after various treatments, to give it an ext by loading it with eifs - this for all vegetable oils even those treated by chemical processes -. For oils with silicones it is more difficult but we have also succeeded. You can also, in certain cases, circulating these oils in specially shaped pipes and at certain temperatures, then an ext appears. This ext, in all cases, is stable over time, by heating or cooling. On the other hand, if other products are introduced into these oils with an ext, this may disappear.

A comparative study is carried out in [1] and [3] to distinguish ext and progenitor on tables of painters, ancient monuments, musical instruments.

The work of J. Ravatin and AM Branca can be obtained at the address 76 rue Didot 75014 PARIS - Phone. : 01.45.42.58.72 (and volumes III and IV of Vladimir Rosgnilk's book at the same address - mail should be sent to Mrs. Branca).

It may happen that different forms have the same progenitor.

A form like the labyrinth of Chartres Cathedral makes it possible to act on the parent of a form ; itself has a parent.

A natural or chemically treated oil has a parent. It is not the volume of liquid who gives it. A silicone oil has one. A transistor has a progenitor but when it is

mounted in a device, its progenitor disappears to enrich that of the device. A crystal has a parent and when it is mounted in a device, it generally keeps this parent.

The organs of a living being have no progenitor because they are organs which are like cutouts from an overly rational view. They become too localized, which can lead to some cases an instability in the room.

Course
2nd level
Paper 18

June 98

Chapter XIII (continued)

1. Consideration on achievements [1] and [2]

Cathedrals have exts, churches too. A dwelling house, in general, does not have d'ext.

The ext in this case is to be avoided. Living day and night in a house that has an exterior can lead to transfers between this ext and the exts of the living beings of this place. We no longer control anything!

We can study other monuments. This is left as an exercise.

All the great castles have not been reviewed. On the other hand, the constructions involved in what are called large sets must rarely have either ext or parent and even more rarely both. The large complexes have been baptized by the promoters, to attract the customer, residential homes. But these are absolutely not residences in the sense that it was still understood there 60 years. These residences had for some an exterior which was impregnated with the neighborhood: trees and woods surrounding the house. Architecture, as J de la Foÿe pointed out in his work [3], is taught and applied indiscriminately; especially since the 2nd World War (for lack of dwellings due destruction), which allowed the horde of promoters to grow in number and in power and to draw in its wake many architects who are only capable of draw cities without souls. In these aberrant constructions, carried out on places which have not been studied for their eifs, there are also very often harmful eifs and even states harmful. R. de Lafforest drew attention to this issue in what he called "The houses that kill". There are also harmful eifs near high-voltage lines: a line of 100,000 volts is surrounded by a sleeve of V'e with a radius of about 80 meters. A line of 200,000 carries in V'e up to 170 meters; a 400,000 volt line up to 350 meters. It is easy to check with pendulum or rod that the "intensity" at V'e does not decrease with distance but remains approximately constant and drops off sharply. It is this V'e which is responsible for many disorders affecting people living under or near high-voltage lines, the electric field between the line and the ground being much less harmful than V'e•

A research group has been set up in France which studies this form of pollution and tries to remedy. This group is called ARKOLOGY. He is particularly interested in the field of investigation of geobiology but whereas geobiology tries by points of view

rational to restore atmospheres which at the beginning are harmful, Arkologie takes again the approach given by the ARK'ALL group and applies it to the habitat, but extends it to a field much more vast which is architecture in general, and even more to Art in all its forms. Extensions views of this group are considered in allopathic medicine, homeopathy, acupuncture, in anthroposophy, etc.

A company, BARKA, 1 was also created.

In architecture, it is not enough to test a house piece by piece to list its eifs and states. The house can be considered as a whole and then the eifs and the states are different than those of each room. Those who live in the house are in contact either with the emissions of a room when they live in this room and when in their representation they place themselves in this room, either with the emissions or the states of the house considered as an entity when they think their home. It all depends on the representation and let's say it again, it's one of the reasons which makes that the dowsers, when they lean on the places, do not find the same thing ; representation of what they are looking for and their definition of the place they are testing is not the same for everyone. It is necessary in architecture to bear in mind what we represent so as to announce the results of these tests according to the chosen representation. We can therefore, if we studies a house to imagine it as the assembly of its parts, or as a unit, the home where a family will live, or even the house and its close neighborhood as indivisible. Can we continue to expand? We would thus have the house and the department or the country etc. It would be absurd to continue such a recursive process and that would misunderstand the approach we are striving for to give since the beginning of this course. From a certain moment the concept house and neighborhood greater or lesser will flee, and if we want to find eifs and states to such a unit: house and very large neighborhood, the leak must be taken into account.

Naturally, the eifs and states of the coins can also depend on the shapes in them, that is, furniture, pictures hanging on the walls or the arrangement of furniture. Example : seats by their shapes, their respective positions and places in the room, can by example having a harmful state or causing a person to sit in an armchair, because it is a seat

1 ARKOLOGY and BARKA can advantageously be contacted and consulted for the construction of dwelling houses: here are the addresses: ARKOLOGY: Mr and Mr Hennemann 77 rue de la République 93200 Saint Denis Tel. : 0142 43 05 14 BARKA: Mr Labat and Mrs Nouvel 31330 Launac Tel. : 05 61 85 77 76

often massive, will be overlapped while she is seated, by another person placed in a another wheelchair according to the provisions previously indicated.

We see that the architect and the decorator have a serious job to do before playing with the forms. Lafforest and La Foÿe have insisted enough on these points in their respective works for we were coming back to it. However, they did not consider what we have established: the exts, overlaps, the study of the house as a whole, etc.

Nor should we make too hasty systematizations here: for example, any clogged well, still containing mostly standing water emits harmful emissions vertically down the well, particular a strong V'e. We could observe such wells in the gardens which had no such harmful emissions, yet clogged, and with standing water inside; naturally this is not the generality. We even found a clogged well covered by a house and there was no harmful emissions in the rooms or in the house as a whole. maybe the shape of the house eliminated harmful eifs? There were also no harmful states.

It happens that in the study of certain places it is difficult to test. There may be a grid, so at with the help of appropriate forms it is lifted; she can stay up or recover as soon as the forms necessary for the test are removed. This grid can be a protection for those who approach the place, it can get up as soon as the inhabitants of the place present themselves, finally a lot of possibilities arise present between the grid, locals and strangers. When we find, after having raised a grid, harmful states, if you don't know how to eliminate them, you have to put the grid back in place. He is sometimes difficult to eliminate harmful states; most often we do not know how they came there, and if moreover there were intentions, it is not easy to know what these intentions contain in possible surprises in order to avoid "backlashes". There may not be a grid on the place, but that the place, the dwelling are in transfer with another place. This case is quite rarely but it must be detected because there is no point in putting a rebalancer to eliminate eifs harmful if any. The place with which the transfer occurs can be near or far. In working on plan, it happened to us to leave the limits of the ground plan therefore not to know the place where the studied house is located. In it the people who lived there could not sleep, they really didn't feel comfortable. By putting a very good rebalancer (and there are few valid) they slept very well for three nights and then everything was back to how it was. Featured study made by A.Orangé and J. Ravatin led them to discover this transfer and the rebalancer had to rebalance the place about 800 meters from the house with which the transfer was made. He deleted

for some time certain harmful emissions from the house, as it momentarily broke the transfer, and then the last reform, the rebalancing was useless. It should have been increase the power of the rebalancer, for example by increasing its volume, its mass or the electrical voltage it was plugged into but it's still annoying to have in a house appliances connected to high voltages. In this specific case, A. Grange and J. Ravatin had imagined 2 copper shapes, one placed in a dining room and the other in another room, which broke the transfer and then the rebalancer had its full effect.

Regarding rebalancers, multitudes have been made since Turenne. Let's just say that he there is no universal rebalancer and that few are valid because many people who manufacturers know little or nothing about the eifs, or if they know them, they neglect the states; he came to our knowledge a so-called rebalancer made by two people having nothing understood to eifs, which sometimes eliminated a few harmful eifs but created almost every time it was installed in a house of extremely harmful states; this device in addition was sold enough expensive which did not help. In this case, to make such a device harmless, it is best to put in two tightly closed plastic bags and then put it in a cupboard or a cellar, it becomes absolutely neutral. We must also be very careful about this: every form has given eifs in a certain volume, by this volume, there is a threshold below which the eifs and the states can change completely. So you should not put a rebalancer in a volume too small if we want it to act for good.

We were able to observe another kind of rebalancer which although it eliminates some harmful eifs, begins to have a completely harmful state in the whole room where he is as soon as he is placed in front of an ice cream. Naturally the seller, when told of this major inconvenience, didn't care. madly.

If we come back to less dramatic cases s P, let us nevertheless point out that it would almost be necessary to study the rebalancer for the place. Finally, certain rebalancers, which are at the same time transmitters (there are very few) can intervene effectively in a significant number of cases. You have to be careful also to the fact that some become "saturated", that is to say are no longer effective from a certain usage time and this without any grids appearing. A rebalancing that saturates, it is enough every eight days, or to pass through running water if it is of a material supporting easily this treatment, either to brush it vigorously etc. Balancers must be oriented, for others it is not necessary. The shape called "Lukxor" must be oriented north of the shape, but this orientation depends on the location, or the size of the room where the

form. We were able to verify once that this localized shape had to be oriented every day because its annihilating power of harmful eifs varied with the phases of the moon; thus appear the very delicate forms of manipulation. It is difficult to make a rebalancer that does not depend no orientation; it must be thought of, during its elaboration, in such a way that it is easy to arrange in different places. It should not saturate. In general, you should not place a rebalancer-transmitter on a television set because its transmitter character disappears and if it is a rebalancer alone, it may very well no longer rebalance anything (a black and white television set sends a V"e at 6 meters and a color post at 8 meters; this was found by A. Philippe). cons, a rebalancer can be placed on a television set if this has been thought of during its elaboration.

It is a good idea not to place the rebalancer near the ceiling of a room, nor at floor level (except some special cases). However, when possible, it is best not to have to put rebalancer. Indeed, if the owners of the house move and take their device and if the environment has not changed, everything goes back to how it was. The architects have therefore advantages in studying the place (basement, presence more or less close to high-voltage lines, transformers, terminals, finally what all our modern world brings), on a plan to take good care of forms (parts, framework, air and water ducts) materials, to avoid gender forms pyramids for example. They are not always harmful but it can happen because the house built in the shape of the pyramid of Cheops is not at all like the pyramid of Cheops internally, neither on rocky ground, nor even if it is oriented like the pyramid of Cheops, with the different environment, different materials, harmful states may occur and even transfers with other places.

A Mexican architect won at the age of 47, in 1971, the first prize in the competition for the Hervico Colegio Militar, the military academy. The biggest project he has done so far is with the 90 million dollars that its construction cost, one of the most spectacular and ambitious projects architectural features of the booming state of Mexico. Christophe Bürkle [4] quotes "Not having so far not covered in any reports - this is a prohibited military area - the Academy represents one of the best examples of the ambition to which modern architects aspire: the synthesis between the tradition inherited from an ancient past and the functionalism of the modern era". Gold this mixture is not necessary at all. The old forms corresponded to needs well precise ones which were not those of workrooms in the sense that we understand it, of dwellings (example of the famous pyramids of Teotihuacan). The construction of this architect includes a

few V'e and Je in places but there are no harmful states. (The V'e exits through certain openings oblique, its intensity varies with the position of the sun). Buildings constructed in a large plain surrounded by mountain ranges are beautiful. But we should not generalize this habit of make pyramids or other imitations of ancient constructions while the architects who launch on such achievements know absolutely nothing of these civilizations in the field

the most important of which is that of the religious practices of the past. Philology is then necessary and not yet philology in the sense in which we understand it but in the sense in which Louis Boutard - Louis Boutard whose immense works will be presented in the 31st level course - understood and applied it.

It's not because in the most remote areas of the Yutacan you can find coca-cola and hamburgers and that the Indians who crowd into the cities buy anoraks in plastics in department stores and are slowly unlearning to dress according to the tradition of their fathers (they no longer even know how to use the old looms), that it is necessary under the pretext to put people back in touch with their so-called origins, to build houses, factories, library, in shapes reminiscent of ancient shapes. It's just another joke. We find this again in the frescoes, paintings, sculptures, executed in the "Indian" style which adorn a many buildings in Mexico City. They reflect a failure to integrate the folklore to architecture. We come across shapes that no longer agree, no longer marry, because they belong to different eras and even worse, they are a mixture of antics of a era with another era. Let's go back to Hernandez: abroad, he was especially noticed thanks to at the Mexican pavilion at the "Expo" in Osaka, Japan. He achieved, from the point of view of many so-called modern architects, his best technical performance with the office tower and workshops built in Bosques de las Lomas, a suburb of Mexico City. He imagined a form of double crossed pyramids and for this he was inspired by the pyramids of Tulum and Tatin. That realization of Hernandez is interesting from the mechanical point of view, resistance of materials. In the 36 meter high tower are the stairwell, the elevator, the rooms necessary for the refueling. This tower is itself the support of the double pyramids which intersect and are themselves carrying elements. In conclusion, we absolutely do not use forms adapted to civilization, linked to other forms only for mechanical reasons, utilitarian and aesthetic, whereas the primary concern of the ancients, which was that form be a approach towards the relocated, is not respected at all. Harmful emissions may occur,

even harmful states, pollution of the place or of nearby or more distant places, all this is possible and is completely neglected.

About the Military Academy of Mexico, built in 400 hectares of land, we are far from the notion of sacred place of prehistoric centers such as the sacred place of Teotihuacan in which one finds large areas surrounded by mountains and this not for the purpose of a defensive wall natural as the architect thought and aped when drawing the plans for the Military Academy.

Of course, it is not forbidden to copy shapes, to impose functionalities on lines, but above all they must not be justified by a pseudo-attachment to the past (the architect expresses himself: "We are aware of our historical background. We must break the imbalance that exists between our own sensitivity and the foreign forms that reach us. Mexico has a cultural heritage that we have no right to squander, because the most important for a people is to preserve its fundamental characteristics"). By taking up initiatives of forms of the past, one can, as they have not been understood in our civilization modern, generate unexpected phenomena of the kind transfers with the past, but with deformations such as very harmful states set in at times and this in an absolutely unpredictable. The misunderstanding of the achievements of the Ancients is too great to try to use, mimicking what is left of it even for decorative purposes only. It's not because that architects, for the most part, are devoid of ideas, no longer have any inspiration, that they have to gargle phraseology to justify their mediocrity. When the inspiration no longer blows, this are not the speeches that replace it. ,Thus triangles, parallelograms, polyhedrons, prisms inscribed in gigantic cubes, succession of pyramidal blocks, use of motifs ornaments from Teotihuacan, as well as motifs from the Mayan and Toltec civilizations, create a mess dangerous. And when Hernandez or his admirers and journalists in search of articles talk about "magical reality of his work", they do not suspect that in these achievements, there is truth to a sense that they do not imagine: magic can appear and where does it lead?... Human beings make much more than he thinks when he realizes. He must pay attention to this.

With architects who call themselves modern, we find ourselves in a situation where we would take a piece of Chartres Cathedral, a piece of the Sainte Chapelle in Paris, a piece of the Arc de Triomphe in Orange, the Porte de Mycène and the Eiffel Tower, to make a library !

The creative breath is only rarely felt in the minds of our time. The expansion fields of research and the very large number of researchers in these multiple fields is not

not an index of deep creation. Researches and researchers only manifest themselves in the C. of usual C.; among the researchers many make only fragmentary assemblages of results without creative power, which rarely leads to far-reaching discovery. others have imagination but only extending the rational C. de C., they cannot absorb the thought of the Ancients and some of their works which have come down to us.

Let's quickly come back to the architecture: it is presented in a language that is absolutely meaningless where the architect seeks on his drawing board, thanks to the lines, volumes creating impressions of "power", of "dynamism": there the architect thinks of a "parallelepiped sinking into the ground" to "break the imbalance between our sensitivity and the forms that are foreign to us"... By this phraseology, which is only an escape from becoming aware of the lack of deep inspiration, one fills the head of the student of architecture with a pseudo-knowledge which will only lead him to research at the level of lucubration and will make him completely ignore its creative role.

This architectural work has been considered here as an example; what has been achieved is found more or less everywhere in other forms, other styles in other countries, other continents.

An architect can plan a lot about states and eifs on his plans. knowing the place, with the plans, it is easy for him to foresee according to the forms and the nature of the materials the harmony of what he achieves with the living. A plan must be oriented; note that the geographical orientation perhaps disturbed by the environment in which the plans, the cards are installed (example: a desk, a table cluttered with miscellaneous objects, natural or artificial lighting). The projects on paper are bathed in the eifs of the workplace; that the architect must make abnegation of it and check if the transfer with the place of installation is correct.

A plan must have enough detail for the transfer to be correct. A map can be used to rebalancing a place itself is quite tricky to put in place. Or we place a rebalancer on the plan or associates it more generally with the plan. This method only works a certain time because although the rebalancer does not saturate, the plane-rebalancer assembly can behave as if there were a saturation, the transfer no longer takes place from the shot to the location. (Here we take awareness of this word transfer which absolutely does not mean passage from one place to another, through a path, but something that enters the characterization of the first place and passes into the characterization of the second).

Exercise :

We make a triangle in copper, or brass, or iron that you place in a horizontal plane.

1) Check that whatever its shape, the orthocenter H - meeting point of the heights of the triangle - is a particular point and that it emits high C. of T., their leakage and even VC and FV

2) Check that if the triangle is made of aluminum, we no longer have these eifs.

3) Gn plants a vertical rod in H which acts as an antenna.

a) Check that we have all the eifs announced below but that we detect them in a sufficiently large volume around the triangle.

b) A hollow metallic sphere is welded to the top of the antenna.

Check that we detect novelties: this is what we have named

Golden Light - LD

Silver Light - LA

Ember Light - LB

Crystal Light - LC

Each is called an FI. There are only 4 lfs.

thus what we also called AVÆCUM.

“Giving a real existence to things

who in the phenomena of nature,

remained in the state of intention. »

Goethe

II. The Creator Word and other elf

If we refer to Goethe's color theory, which was opposed to that of Newton, and did not recognized, it appears that Goethe insists on the so-called peach-blossom pink color. We call her now red-magenta or magenta.

If we test this color - which is not in Newton's spectrum - we find an eif that we named Creator Verb (VC). Moreover, a word in Old Sanskrit emits this eif, and this word means Creator Verb - It is also from this word that we discovered it

Shortly after we found another which we named "Famous Green" (FV) to distinguish it de V, V+, VjM, V+ M, VjE , Ve.

Remark :

If we examine carefully certain paintings representing religious scenes, we realize that colors: green, magenta, golden yellow, red, azure blue, are often present - The painter, he seems so, brings in these colors to bring delocalization into the painting. What's more, by testing, we realize that we are not in the presence of the eifs of the EFF spectrum but of other eifs which are not the C. de T. and their flight, this is how we place VC and FV and something else that are not eifs but which we call IFS (IF for inter-face, as if it were placed at a interface; this analogy will be forgotten later).

III. SFIs

1) Classification

We get 4 lfs:

L.D.	Golden Light
THE	Silver Light
L.C.	crystal light
L.B.	Ember Light

Now consider the Light and Darkness of the Bible, which is not at all black and sunlight in the sense of classical physics.

Let's do (FV, Darkness; VC, Light). This has a halo. Let's call it Golden Light.

We see immediately that LD is not an eif. It's as delocalized as all the eifs envisioned so far. If we look carefully at certain paintings depicting religious scenes, we

fairly often sees colors green, magenta, golden yellow; it is possible that the painter put the accent on 3 colors to evoke the delocalized, that is to say the two eifs: VC and FV and the aureolar LD

We will refer to the exercises for the detections.

You have to be careful and only name other eifs if you really need them! A little color known, because used only by painters and not at all by physicists, and on which Goethe insisted a lot, is the one named by him "pink-peach blossom". We have it now called red-magenta or more simply magenta. She's not on the spectrum Newton, but it is found in Goethe's spectrum. If we test this color, we realize that it emits an eif that is not in any of the previous ones. We call it the Creator Word and this because we can detect it on a word in Old Sanskrit which means Creator Verb.

2) Consequences

So we still found new eifs and ifs; this was possible and will remain so for what follows, because we kept in mind the idea that the previous set of eifs was perhaps not complete? Someone who would have liked to restrict these eifs to the drawn set of colors with at the strict acceptance of E and M, would have found some of these eifs to characterize the "magenta". He wouldn't have been wrong! Roughly speaking he would have described with consistency. Is this consistency sufficient; There is the question ! He will approach the continuation of this research with this consistency. Note here that the choice of eifs is not consistency, it is only the beginning of consistency. It contains the state of mind of the researcher, even what he will do with it afterwards. The choice of the eifs for example is only a question of appreciation of the researcher-obs. Everything we say for the eifs is true for the rest. This is also true in the rational domain, and since we live in the usual C. de C., it lends itself very well to this: it is that we identify much better the elements of the selected sets. Let us not forget that in the usual C. de C., the choice of the set and elements is simultaneous; it is only in the formulation in the usual C. of C. that one constructs the elements as a whole. Tacit knowledge, or rather research into the implementation of the tacit knowledge of the rational C. de C., is not in the rational C. de C..

Why do we say that the choice of the set and the elements is simultaneous? Because it has no sense of seeking one before the others or vice versa as existence in relation to a origin of time. The birth of the whole and that of the first elements is not in the story awareness of their existence. If we want to build another story which would be the one

of their separate existences, it doesn't make sense. No more than that of their existence starting simultaneously as we said above, but here we were only preparing the reader and we put it in a dynamic thought, which moves as it evolves, which adapts at the same time that it evolves which makes it very obs, always origin. There is only the instantaneity which is not limit towards zero of duration, but rather perpetual catch-up of birth of duration. The perpetual is in catching up with the appearance of any duration. In the world rational the perpetual is rendered by the continuous or the quantifiable with the relation of total order. So if we go back to the construction above, we now understand the concept of Enel presented in [1] The human being carries with him, in him stories, his memory is filled with history but also his attitude and his descriptions of others, of others who are in C. de C.. A story is a piece of coherence or a description using pieces of several coherences. A story can thus cross coherences belonging to a C. of C..

Cyrano de Bergerac [5] writes: "I was beginning to fall asleep in the shade when I saw in the air a marvelous bird hovering over my head; he supported himself with a movement so light and so imperceptible, which I doubted several times if it was not still a small universe balanced by its own center. He descended, however, little by little, and finally came so close to me that our eyes relieved were full of his image. Its tail looked green, its stomach enamelled azure, its incarnate wings, and her crimson head shone, waving, a crown of gold whose rays sprang from those eyes. He was a long time flying in the clouds, and I held on so tightly to everything he became that my soul having withdrawn and as if shortened to the single operation of seeing, it barely reached to that of hearing, to make me understand that the bird was speaking in singing".

We will not go further in this text, but retain the colors which allude to VC, FV and LD. There is also the evocation of an azure color; we don't have any eifs to match it. In alchemy, the two eifs VC and FV as well as LD which is no longer an eif, are necessary.

In summary, we have seen:

- The two spectra: undifferentiated and differentiated, consider the continuums. These eifs are called:
EFF level eifs
- Then the Taofel Fields and their escape.
- Ensuite VC, FV
- Then LD, LA, LC, LB which are Ifs.

But have we exhausted everything! It seems that with everything presented above, we have a good arsenal to its disposition for all that concerns forms, living systems, the rebalancing of places, dwelling houses etc.

We have not spoken of the states, the first time evoked by de la Foÿe, nor of the atmospheres established by Ravatin. Indeed, if states and atmosphere are necessary for the study of forms, this is no longer eifs at all nor this other thing that is LD. On the other hand, state and atmosphere are to be taken into account for everything that relates to forms and unfortunately many people interested in this field or pretending to be interested in it completely ignore them. There are even which make states of the eifs. This is the big mess in their results and interpretations.

Exercises:

Check that the sap emits VC

On the other hand, if it is extracted with a centrifuge, VC is no longer detected, even if an artifice is applied detection with the left hand: the thumb on the little finger and the other three fingers two by two side by side and directed towards the container containing the sap.

If left to stand, the sap extracted by VC centrifugation comes back but less clearly.

If we want to extract the sap and keep it VC, it is necessary to bend the plant but not to twist.

Dew has an ext but not VC

Exercise :

Let's take a magenta screen and illuminate it with white light.

On the other side of the screen there is a magenta color radiation.

- 1) We then illuminate a piece of nickel by this radiation: check that we have very clearly VC
- 2) If we place a crystal in VC, we detect a channel.
- 3) It is very strong if we replace the crystal with iodargyrite and even stronger with kasolite - These stones can be ordered from crystal merchants -

3) Notes

We can use certain bulbs which give off magenta lighting, i.e. we detect VC on the path of the light rays. Multiple assemblies are possible, for example putting the bulb between the spark gaps of a multi-wavelength device by Georges Lakhovsky or still put it in an energizing pyramid. We can detect VC in the Universe. You have to

look into what is called in astronomy: the jets of galaxies. It was in 1918 that such a phenomenon (publications of the Lick Observatory in California). Astronomer HC Curtis notes that the nebula Messier 87 (nearly round) has a curious straight ray, apparently connected to the nucleus by a thin line of matter [6]. At this time, approximately 150 jets have been listed.

These jets consist of high-energy particles confined in a very narrow area which gush like water from a small hose under high pressure. In the case of the M8, working on the photo, we see that there are several decals and "channels" in the galaxy and outside it. We detect VC in a portion of the Universe which is very large compared to the volume of the galaxy and jet. But here we have to be careful, we only detect the VC because we consider a very large volume. If we place ourselves at the level of the volume of the galaxy, there is no VC; he ... not must not forget that we are in a field which is no longer rational in the sense that we manipulate notions describing existence without landmarks. The radio jets of the galaxies are not always rectilinear, such is the case of the galaxy NGC 1205 located in the center of a cluster of galaxies. We detect well VC in a large volume, as before. On the other hand, it seems that there is such a jet leaving our galaxy; if we test, we can't find a VC, the volume probably not being enough for the test to be positive.

Exercise: Put a Newton spectrum on a black background. Check that we find FV The latter is amplified by a colorless glass ball; the amplification is greater than if it is a ball in wood. If we put an iron ball, the FV disappears. If we put a piece of germanium in the FV, we get VC.

Exercise: Consider 2 round or square transmitter plates and a mercury tank. let's broadcast one of the plates in V_+ and the other in V_- , i.e. at the exit of V_+ one recovers respectively the V_+ and the V_- and immerse the two wires in the mercury tank. Then check that it comes out of the FV tank Replace mercury with water and V_+ and V_- with R and V_i , it comes out of water VC In these two assemblies one can use only one disc with two needles, but it is necessary arrive, for the first, in the mercury, and for the second, in the water to have these new eifs.

4) Note

We can therefore see that the composition of the eifs is very delicate, because it depends, in the previous case, on the transmitter trays, and other shapes. Thus we check once again that the approach of the shapes presents itself quite differently from that of technical objects.

During the research a new fact appeared and this about LD and LCJ, de la Foÿe had introduced polarity into his study of forms. There are two polarities; they detect each other with pendulums on which right- or left-handed helices are drawn. Forms have these two polarities, others don't, still others are strange, because you have to use both pendulums (polarity D and polarity G) simultaneously to have an answer; for the latter seems, in some cases, that the two polarities are confused at the same point, for others it has a completely different meaning, which we do not know. Maybe we should think Dd between polarities or one of the other concepts presented in [1].

But there are no polarities for eifs; this only applies to shapes. It was thought that it existed something else equivalent to LD and LC and this by taking the notions of ethers from occultists and especially alchemists for whom there were four ethers (see [1]).

1. The ether of heat with which the radiant forms in balls are associated.
2. The ether of light with which the forms radiating in very fine beams are associated, for example: fern and acacia leaves.
3. The ether of chemistry with which forms of the oak leaf type are associated.
4. The ether of life with which are associated the cruciferous, pentameric and hexameric forms.

For occultists, their imprecise language means that the ethers can be confused with the aether by L. Boutard. Rudolf Steiner used these four terms in the language of occultists but this has been immersed in his thinking and takes great interest given the quality and depth of his research. R. Steiner had a personal coherence imbued with occultism but an intuition dazzling which left him the possibility of using a not very evolved language to arrive at results amazing. For us there is no question of confusing these four ethers with that of L. Boutard. They have common characters in that they can be considered reflections following certain interpretations of Boutard's aether. And the aether built by Boutard is a description following a representation (that of Boutard) of Æ defined by our care as a halo in [1]• We have therefore named Silver Light and Ember Light these novelties. Ravatin after having involves the notion of male and female in the equivalent of the interface (by transport of structure) has set up the character:

LD and LC have the masculine character

² The notion of interface will be justified after the presentation of the avæcum.

LA and LB (LA for Silver light and LB for Ember light) have the character feminine. The alchemists use this concept when they speak of the sun which is masculine and the moon feminine (which moreover respects French grammar). It should be noted that the sun has a very clear masculine character whereas to detect the character of the moon one needs a form developer.

Let's make a solid wooden sphere and cut caps to make a cube with edges and ends rounded. Let's put this shape near or against an amethyst crystal: it comes out LC and LB. The male-female pairs are LD-LA, LC-LB. LD-LA can be in Dd, in equimsey or one overlap the other, same for LC-LB. You can even combine 3 of the 4 or even the 4 together. They can also be inserted into a TAG system. As by transport of structure from the idea of interface, we placed LC, LD, LA, LB; we remind them that we assigns the name of IF (IF: for Inter-Face). So we have four lfs.

Consequence: We present a short study on Sathya Sai Baba.

A. Crani in [7] writes "it was in 1953, when he was twenty-seven, that Sathya Sai Baba addressed for the first time to the crowd, thus beginning the cycle of his teachings. All his speeches published were translated from the original Telugu into the English language by his biographer, Professor Kasturi. They were published in ten volumes. The first volumes in French language seem little little. "The discourses of Bhagavan Sri Sathya Sai Baba are as important as the Bible and the Gospels for Christians, the Koran for Muslims, the Vedas for Hindus, the Gathas for the Parsis and the Buddha's teachings for the Buddhists," says Crani. He It seems that Sai Baba himself declared that his speech is real spiritual nourishment which gives strength and courage to every sincere aspirant to advance on the path which will bring him to his own implementation. His speeches contain advice, reproaches, little spiritual oaths under forms of admonitions. Sai Baba says "I have come to answer the prayers of saints, wise and faithful who called me and to recover the moral law (dharma)".

We can test Sai Baba. One notices first that it is in equimsey with something else; we do not know at the moment what it is. It emits high C. of T., their flight, VC, FV and yew. He in his system by equimsey and not him alone, has a very strong ext and an int. [1]. When he participates in the Abisheka ceremony and there occurs the location of sacred ash on the 3

3 See the rest of this booklet.

statue of Shirdi Baba during the great night of Maha-Shira-Rathri, the vessel from which the ashes emerge responds to decalaire. The ash has eifs and the yews of Sai Baba (from the Sai Baba system in equimsey with...). When Sai Baba locates a statue of Krishna in the sands of the Chitravati River [8], the statue has ext and int, [1]• it also has the preceding eifs and ifs. The statue emerges from a decalaire.

IV. Gate

When one wants to detect with pendulums and rods and when in particular one works on witness (plan, photograph...), it can happen, this is quite rare, that the answers to the study are unforeseen and even that there are none at all. In this case we realize that we are in the presence of what is now called a grid. Grid because everything happens as if the detection was partially or completely obscured. A grid can be wanted by those who do not do not want a detection to be made on the forms, in the broad sense of the term, to which they are interested or have been interested; it can appear on its own.

When during a test, you come across a grid, you have to lift it. For this a ritual or forms are set up on the plan, photograph etc. The gate can remain up after the ritual has been executed or the forms have been withdrawn; more often it falls.

A case where a grid is found is cited in the work of V. Rosgnilk [2]: the Miracle of Lanciano. We develop it here.

Note that the grid may not exist for everyone.

Lanciano is a city in Abruzzo; around the 700s was in the monastery of Saint Légoncien, where the monks of Saint-Basile lived, today the convent of Saint-François, a monk who went from day to day doubting that in the consecrated Host were present the body and the blood of Christ. However, he constantly prayed to God to remove from his heart this wound which afflicted his soul. While one morning, after speaking the words of consecration, he found himself more that never sunk in his error, he saw the Host being transformed. The Host had turned red blood, it appeared to be a piece of flesh and the consecrated wine to be actual blood which coagulated into five irregular clots of different shapes and sizes. The monk turned to his followers to share with them his amazement and his joy at the miracle It may be that at the beginning of the red coloring blood, the monk, taken by stupor (state favorable to transfers) projected on the transformation, miraculous indeed, in progress, his hope and his distress and then the orientation was made towards flesh and blood. But it's only an hypothesis ! From 1574 until recent years. all the

. historical course and details of the experiments can be found in [8]. a few pages are devoted to it in [9]; this work is interesting for the multitude of miracles of this type or other strange phenomena of a religious nature listed and described.

It appeared a few centuries after the miracle, a grid, which makes it impossible to test correctly; the mass ritual, done in this church, raises the gate for the duration of the mass and then it falls. Very strong eifs appear and permeate the celebrant and the faithful who follow the office. But the impregnation can last after they leave the church. Transfers, when the gate is lifted, may occur with other holy places. To this it is necessary to do very attention.

About these grids people claim never to find any because they consider, and in that they place themselves in a position of superiority, which they are strong enough to lift, without knowing it, the grids therefore get rid of this concept. Geobiologists, on the other hand, do not know completely.

These are attitudes that are often encountered in non-Orthodox fields, where so-called researchers tend very quickly towards positions which they create for themselves, which are very privileged. They crown themselves.

In the case that concerns us, the negation of the grids corresponds only to a search for power that completely erases the search for subtlety that is brought about by the understanding of the necessity of the grid concept.

To deny this concept shows a lack of subtlety with respect to what one wants to approach.

Another concept is also necessary: that of the diving suit. Indeed it happens that after many attempts on forms, places, we find nothing and that by looking for a grid we also have no answer.

Another concept is then necessary: you have to wait and images come to mind; we see the shape, the place as if enveloped, we think of a diving suit and we test; the answer is positive. So we adopt this concept.

In reality grid, spacesuit are used by transport of structure - the concept of track seen in the previous booklets -.

Conclusion : it is necessary, when forms, places are under grids or in suits, to test them, remove these grids or suits.

So for that we use shapes like constellations but also something else.

v. TAG system

Let's look at a very specific shape before continuing: for this let's consider two loudspeakers identical G1 and G2 separated by a corridor H.

These two enclosures can be made by 2 pieces with a rectangular horizontal section and trapezoidal vertical section. The roof is therefore sloping and equipped with two dormers which are in the roof plan. The 2 pieces G1 and G2 are symmetrical with respect to the vertical plane of symmetry H.

Two doors, so symmetrical allow to enter by a corridor in G1 or G2.

First assume the two rooms are empty. Due to lighting, location etc., we will have a atmosphere in G1 which will be the same as in G2. We will call "Atmosphere" the atmosphere of G1 and of G2 which is much more abstract than the mood of G1 and the atmosphere of G2. For the system G1, G2, H, there will be an atmosphere. The Atmosphere is not a state or an atmosphere. In G2 in a place we can put a shape and place ourselves in G1 to the symmetrical position occupied by the form in G2. Thanks to the Atmosphere we can work as if we were next to the form placed in G2 when we cannot see it. This allows to be very effective on the form. the system G1, G2, H will be called system T AG (T for transfer, A for atmosphere, G for generation).

Consider the human brain. There are two hemispheres and between them the corpus callosum. We don't we will consider that this: we are not quite faced with a T AG system. Of course you have to to suppose the existence of an atmosphere in the sense or we presented it above; this one not being not located, it could not be detected.

Let us now consider the Obs, the pendulum, and that we represent (model).

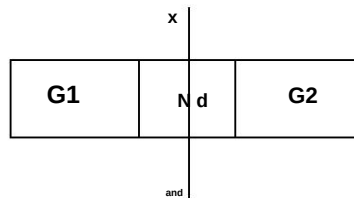

Let's tackle the T AG:	1st hemisphere, corpus callosum,	2nd hemisphere
	x	4ÿÿ
		x
the system	Note	Pendulum
		the model

According to the correspondence indicated by the arrows. To know how to use a pendulum is to allow tackle to create between the Obs and the model a particular position (everything happens as if by plating The Obs was getting into a hemisphere, or G1 the model in the other hemisphere, namely G2 and that the positions in G1 and G2 are symmetrical with respect to a place passing through the body callous).

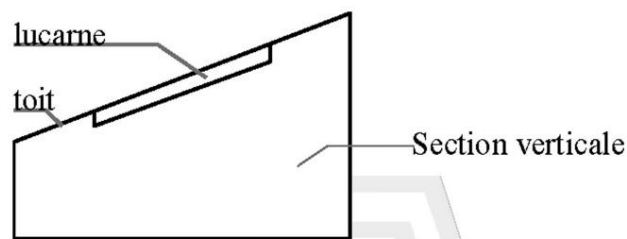

The plating on the TAG of the system (Obs, pendulum, model) as we indicated above creates an atmosphere, and at that time the TAG is the plated system as well, resulting in

the operability of the obs on the model. Here is an overview of the dowsing process. It's a little more complicated because the model is not the reality. To go further, it is necessary to involve again the notion of equimsey.

Let's summarize the above: Consider two identical G1 speakers? G2 separated by a corridor H.

These two enclosures can be made by 2 pieces with rectangular horizontal sections and trapezoidal vertical sections.

Chapter XIV

In this chapter, many of the montages reported to produce Avoecum are left as exercises.

I. L'AVÆCUM

The Avœcum was discovered in December 1986 by J. Ravatin. He had a presentiment of its existence - naturally not in the rational sense of the term, but existence linked to the global - for several years.

The Avoecum behaves differently from all of the above.

We can verify that a Sprink-type device - we talked about this work in a previous fascicle - does not emit Avoecum.

Georges Lakovsky's multiple wavelength oscillator - which will be seen later - does not emit no avoecum

On the other hand, the assemblies of JW Keely, the orgone guns of W. Reich, the apparatus of Louis Boutard emit from P Avæcum.

It was necessary first of all to find a form to emit avæcum. J. Ravatin imagined, for produce the avæcum what he called an avæcum cannon. This is made up of a wooden parallelepiped with cavity containing different bodies and in which a wooden prism. The square section prism has a greater effect than a cylinder. The prism is full. Under specific conditions, this cannon emits avæcum. It should be noted that the detection is done in the straight extension of the wooden prism, it begins at about 20 cm but this distance can vary according to the importance of the gun. Moreover there is no dispersion. That looks a bit like a laser beam. Note that we often had this with the eifs but dispersion could appear at the tips of the needles of the transmitter plates if they were not very sharp. Here in addition, what is quite new is the "range" of the barrel which is measured in tens of thousands of kilometres.

The eifs would be to the avæcum what the foam is to the waves. What is written (eifs, avæcum; foam, waves) and this has a halo that for the moment we do not know.

The avæcum is a unit; there aren't many like eifs. On the other hand, it seems that he has two components which are not of the avæcum, this is why we say that the avæcum is a unit.

These, pictorially, can be described as follows: a mass component, dark gray containing the other component formed of orange-red colored sinusoids, deforming very slowly and moving in translation⁴. It is a possible representation. There is no harmful state in general which is attached to the avæcum or its components.

⁴ The advantage of such an image makes it possible to formulate in depth the entity Avæcum. Such approaches are very common in this field. They resemble dreams which themselves are extraordinarily rich. It is the intention that intervenes in this case. Let us quote information provided by René Clairand on Hugues Pamassié, specialist in Jazz, and who had achieved constant clairvoyance by drawing all reflection to him for the benefit of the imagination. He said, among other things, that one does not dream because one sleeps, but that one sleeps carried along by the dream which is established in view of the rest due to sleep. Hugues Pamassié died on December 8, 1974.

Thus, let us stop at this thought of H. Pamassier. We do not have a permutation between sleep and dream: Usual point of view: We dream because we sleep, which we will summarize as follows: sleep => dream Point of view of H. Pamassié: we sleep trained by the dream which is established, but in view of the rest due to sleep, which we interpret thus after having posed: Ext (awakening) = dream in the sense of the dream and (sommeü)ýdreve = rest Thus is expressed the Pamassie's point of view.

We can also take the rational point of view by completing it as follows:

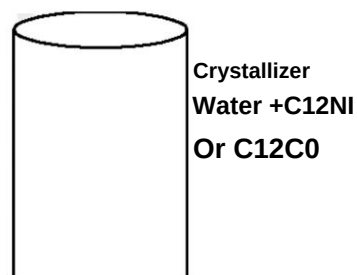

With Taveecum, all eifs can be spawned. From the eifs one can also go to the Avæcum, by example if one sends VC on the star of David, one obtains avæcum.

You can load metals in avæcum, you just have to place them at the exit of the barrel. If we heat them they lose this avæcum; there are however exceptions: for example lead, gold, platinum keep the avæcum to fusion, and even this becomes stronger.

Chromium oxide (Cr_2O_3) in pieces (it is difficult to obtain this way, because it is always sold ground into a fine powder) and chromite (which is a mixture of chromium oxide and impurities) both emit from the vacuum and at very long range. But let us be clear, the oxide must be of chromium, if it is about him either, in pieces. If the powder is agglomerated, this does not produce. Mixtures of chemicals can emit vacuum; we have a use direct for unorthodox research, of constituents of the usual C. of C..

To “amplify” the avæcum one can put chromium oxide in a spherical cavity. He it must be in pieces.

One can also amplify with solutions of nickel chloride or cobalt chloride which one puts on the beam. There is no deviation. We take a cylindrical glass container.

77777 L »77777 M 77777777777777777777777777777777

One can also amplify by sending the beam on old light bulbs, on empty or full bottles.

There are forms which are like reservoirs of avæcum - we will say "reservoir" when we can make the system a transmitter of avæcum -. Let's look at some examples: first let's consider

sleep, U, rest, => dream,,

We cannot bring in the concept of overlapping, this concept has no meaning in the usual C. de C..

moving clouds on the sky considered as a background. The whole constitutes a reservoir d'avæcum.

One can, with an appropriate supplementary form, draw from the favæcum of these clouds in movement. If we don't have the concept of form over substance, what do we detect? We will not detect a "reservoir" of avæcum! If we have the concept of avæcum and someone places a shape that triggers in delocalized the presence of avæcum, we can detect this avæcum. If moreover we do not have the concept of avæcum, one may very well not detect anything at all. It happens that when you don't have a concept, nothing is detected, or the test suggests the concept.

It can also be found in a somewhat similar case thanks to the movement. consider for this a locomotive which pushes wagons on a ramp for the sorting of a train. The wagons separate on the descending ramp and then take different tracks thanks to switches. Let's consider the whole of this train, let's say "exploded" constituted by all these wagons alone in motion on different paths. This "exploded" train in motion in the station of triage (if alone) is a reservoir of avæcum.

The starry sky (without clouds) during a night is in motion. It is the sphere of the fixed ones. If we puts on the ground, suitably arranged, the five hollow Platonic solids, made of iron or copper, about the same sizes, one has a reservoir of avæcum. If there are clouds in the sky, night, without moon, it is still a reservoir of avæcum. The five Platonic solids delimit a area with a particular interior.

Three crystals: a purple, a yellow, a green and not just any; for example: purple opal, natural citrine, machite; which, moreover, all three are in contact constitute a reservoir d'avæcum.

Consider a dynamizing pyramid: it has a square base, it must be associated with a number that is neither the golden ratio nor the radiant number. We have a canal in an area near the center of the height of the pyramid. Let us place in this region the three crystals in close contact, it comes out of the avæcum, C. de T., and also VC, FV, and LC.

Let's take the three crystals, still in contact and subject them to an electric field, it does not come out no more avæcum but VC, FV, LD and LC If we place the three crystals, only in contact, at the top of the head, we charge in VC, FV, LD and LC. The human body transforms the avæcum in these eifs and others and also in C. de T. and their flight. A stone that has a CP, placed on a piece of wood is a reservoir of avæcum.

Menhirs surrounded on two sides by half-trunks of dug trees, vertical, are reservoirs of *avecum*. It should not be inferred that the menhirs were caught between two such pieces of wood.

If you take pieces of obsidian and put them in powdered chromium oxide, it emits *avecum*.

Consider a TAG system [1] and [2]. Let G_1 and G_2 its symmetrical speakers compared to a central hallway. Let's put in a point of G_1 a piece of chromium oxide and in symmetrical position with respect to the plane of symmetry of the system, water; water takes on *avæcum*.

We have seen that a solution of chloride of nickel greatly amplifies the *avecum*. It is the same for bromine water, or water colored by iodine.

Just as the closed glass bottles, placed on a bundle of *avæcum* strengthen it, a amphora strengthens a lot.

Crystals charged with *avæcum*, pressed or heated without destruction of the mass crystalline emit even stronger.

If you aim an *avæcum* cannon at the decalar of a Sprink device, the decalar disappears; It is replaced by a channel which can be detected in the entire extension of the barrel.

If we send a beam of *avæcum* on a decalar, the decalar disappears, but all along the bundle of *avæcum* a canal is detected. Naturally when we talk about a decalaire, we assume implicitly that there is an escape from landmarks; the *avæcum* is delocalized but the beam is identifiable, we can send the beam in a direction on which the leakage of the markers occurs. He is interesting to remember that the local is a support for the delocalized.

We will also see in the study of the planes, and more generally of the surfaces attached to the cathedrals and certain large buildings only by using a structure of projective geometry realized for the points by hollow spheres, connected between them in an adequate way, one creates eifs to C. of T. raised and their flight, VC, FV, LD and LC, but also from the *avæcum*. This structure constitutes an aether pump. Let us have decalaires in certain regions of space, in number given by the order of the chosen projective geometry (this order there is an integer and the number of points or lines of geometry is given by the formula $k+k+l$. We notice that the case $k = 1$ does not gives nothing of interest in the domain where we are), it appears paths between these decalaires which are of the "canal" type. We have as many "channels" as decalars, since points and lines in a projective geometry are of equal number.

We can find other simple and compound bodies that are at a certain distance from each other will produce powerful avæcum, but there is something more. We don't know yet what it's !

Jacques Ravatin noticed that at the time of the solstices - a night close to the solstices -, Earth is bathed in a sort of "rain" of eif which is VC. It's not continuous. We detect them approximately every 30 seconds to 1 minute. It is stronger at the summer solstice. The night of June 24 to 25 1987, it started at about ten past midnight until 4 am. The period is not constant; we had stops of 20 to 25 seconds per moment and we detected very strong VC for 45 to 55 seconds, this around 1 o'clock in the morning. The avæcum emitted by a cannon was transformed into flight from C. de T. during VC detection. There was even alternately high C. de T. and their escape; immediately after 4 o'clock in the morning the avæcum was found.

Let us point out that the Arche d'Alliance emitted the avæcum and likewise the Grand Chandelier at 7 sept branches when turned on in a certain way. In the case of the Ark of the Covenant, the two kerubim sent the beam vertically. Two winged goats face to face emit avæcum, likewise two winged bulls. If we put two winged human representations face to face, it is much stronger.

The amplification of the avæcum can be made at the exit of a barrel having perpendicular to the floor and beam 10 double mirrors. The distances between the mirrors vary with the orientation of the beam of avæcum and the place where the experiment is carried out. You have to choose the distances between them carefully. You can also put two hollow concentric spheres on the beam, it amplifies.

You can also amplify by attaching a metal ring to the cork pushed into a bottle empty. The plane of the ring must be vertical and it must be broken at its highest part. If the bottle is potbellied it's even better. We can make batteries of bottles and rings but if you do not want the beam to be extinguished or to be diverted, the bottles must be connected between they.

It is possible to reflect a beam of avæcum. One or two mirrors do not have this effect; it

ÿu

three are needed with very precise angles between them. A shaped swastika , drawn horizontally in the ground and crossed in its center by a vertical rod emits from the avæcum. This is not the case for the symmetrical swastika of this one with respect to a straight line.

One can bend a bundle of avæcum. It is necessary to plant in the ground pieces of wood with section square according to the diagram that will be found later.

You can put two identical guns face to face. It no longer comes out of the avæcum but in the center of symmetry of the assembly, perpendicular to the axis of symmetry, we detect high C. of T. If we places 3 identical guns directed along the axes of symmetry of an equilateral triangle, and corresponding by rotation of 120° , nothing is detected, it is an absorbing form. Yes now we consider 4 identical guns which correspond by rotation of 90° , we detect something but it's not in a close neighborhood of form.

It is not detectable in a region of space. The AND structure can no longer be used to determine an area of action. We are not facing an avæcum or EF reservoir. It's good something else. Until now we had more or less relocated but the effects could be manifest in regions of space. Here we can no longer rely on close neighborhoods or distant or even distant regions. The study is very complicated.

Suppose now that we have a form that sends avæcum in all directions. If we wants to channel it just press against the shape a solid wooden prism or a wooden cylinder also full; the avæcum is detected in the extension and is no longer detected elsewhere. It's necessary avoid putting an avæcum cannon in a house. The avæcum can be amplified or it can be turn into multiple eifs and in some cases it can be harmful.

The avæcum carrying very far, one can send some on a mountain for example. If the massive mountainous contains ice, and that one sends it on this one, the avæcum is amplified, but the amplification is felt even close to the emitting cannon (if it is sent by a cannon, this is often practiced because we have a beam that is easy to direct). If we send the beam on a massif mountainous supporting a lot of vegetation, the avæcum is transformed on the massif into LD, LC, VC, .FV. If we send avæcum on a forest we detect as in the latter case LD, LC, VC, .FV or some of them⁵.

Some words pronounced several times make the one who pronounces them send avæcum. Those words do not always belong to a humanly known language. They have to be made. One can

ÿ If we send VC on mother-of-pearl, we obtain favæcum, whatever form is made in mother-of-pearl. If we send FV on mother-of-pearl, we get ifs.

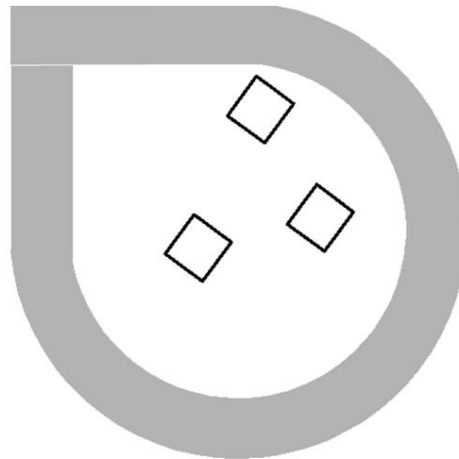

© EÜREECALL

direct a beam of avæcum on the sun: we amplify if we put on the path of the beam a yellow filter; if this filter is magenta, it is even stronger.

Canon

Here we do not detect anything

Deflection of a beam:

Three vertical wooden prisms
Their positions are very precise
The prisms have square sections.
A diagonal is parallel to the axis of the barrel.

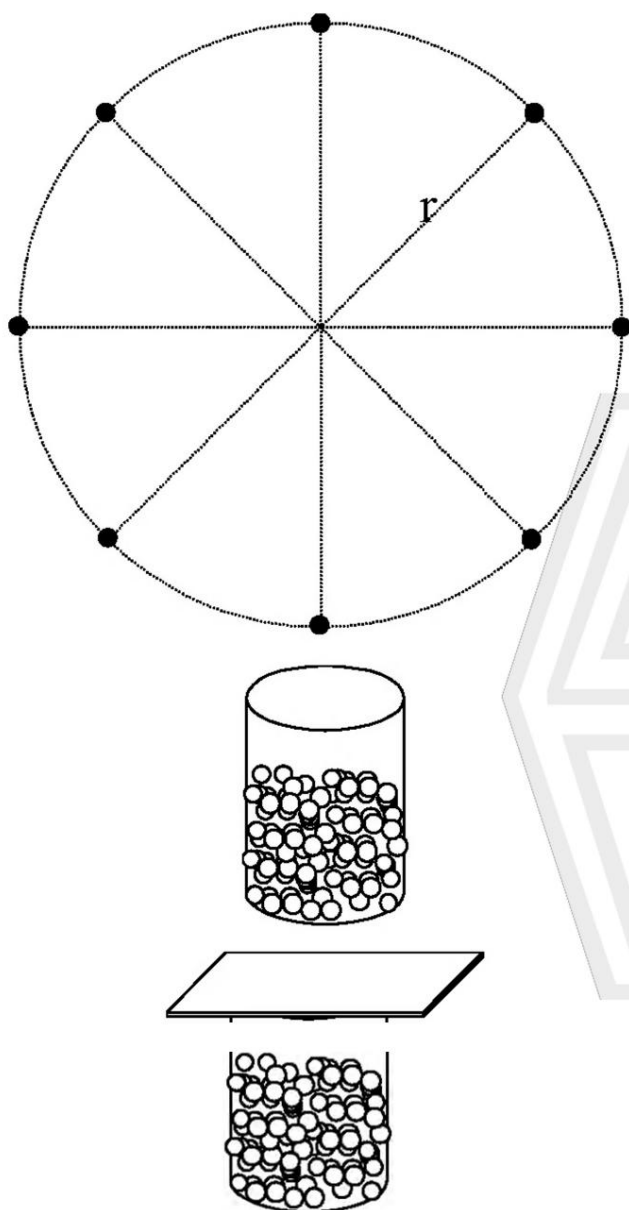

If we consider the following assembly: 2 barrels whose axes are in a horizontal plane and perpendicular. Let us put the zone of intersection of the two beams in a hollow tube placed on the ground like the cannons and such that two faces are respectively perpendicular to each beam. We amplify but on each outgoing beam we detect a channel.

It can be seen that the amplification methods are multiple; only a few have been cited. One can find many more. As for the eifs, you have to be careful if you want to amplify to ne not transform.

Religious buildings: churches, cathedrals, synagogues, multiple temples do not emit of avecum. But we can make them emit it not by the usual rituals, but by manipulation of this that we will present in other studies which will be the planes, surfaces, volumes linked to forms. These planes, surfaces, volumes are not the shapes usually seen, completely localized or even partially delocalized.

Let us give some complements on witnesses of being alive or dead. Let's put in a bottle, colorless glass, filled with water, a piece of bone, then the bottle is sealed and placed in a bundle of avæcum. There is a strong amplification of the avæcum. If in the water we send a few

drops of nickel chloride, the amplification is even greater. Let's take the bottle that one fills with water sprinkled with clay: let us put a piece of flesh of living being, the avæcum is amplified even if there is no clay. Always with the same bottle in which we put pieces of clay with a picture of being alive; there is amplification of the avæcum as soon as the vial clogged is put in the beam. If the living being is dead, the avæcum is partly absorbed. If the being is alive, the FFV is detected in the beam. If the being is dead, and we put the letter aleph in the beam (written in biblical Hebrew), one detects the FFV.

Steel balls can, in some montages, create avæcum. 8 marbles arranged at the vertices of a regular octagon and one at the centre.

Ball diameter: 26 mm to 30 mm.

Radius of the circle circumscribing the octagon: 1 m 40.

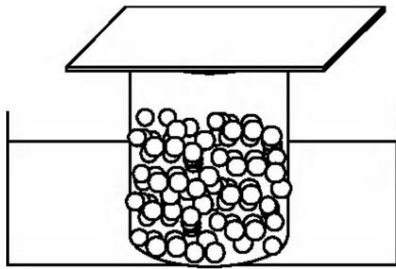

The box is made of tin (the interior must be reflective like tin but not colored).

Inside the balls are made of steel.

On the tin box (idem previously), a mirror whose reflecting part is towards the outside of the box)
steel balls

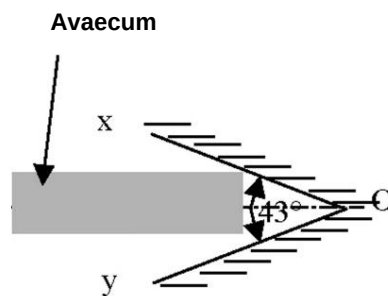

The avecum is stronger.

© EÜRECALL

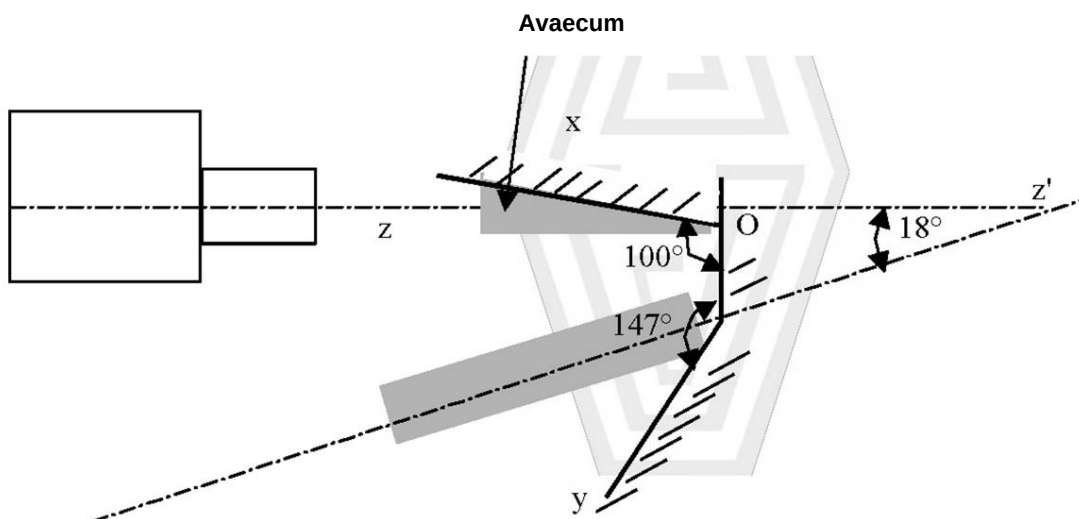

The assembly opposite is immersed in a crystallizer containing water.

The avæcum is stronger and can be detected very far away.

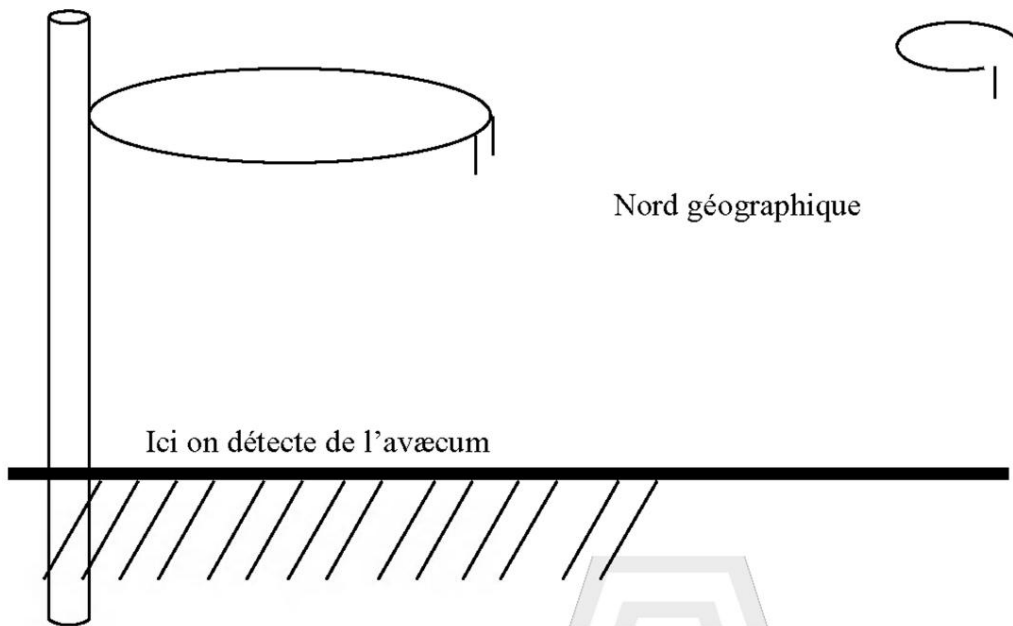

The avæcum is detected closer to the barrel than when there is no mirror. Nothing is detected in the part of the exterior plane at the angle $xOy = 43^\circ$. If we take an angle such that xOy but of value different from 43° , the beam crosses with an amplification effect.

Case of a reflection of a beam. You need three mirrors. If the angle of incidence between the zz' axis and the xO plane increases, the angle between the $z'z''$ axis and the $O'y$ plane decreases. It usually takes 3 mirrors to get beam reflection. We see in the figure that the form formed for these three mirrors is important. Reflection with a single mirror is possible; it follows the laws of Descartes for geometrical optics, but something else must be inserted into the editing.

Ravæcum can be obtained from VC by sending with a Lakhovsky oscillating circuit the CV. You have to respect the editing as Ta describes G. Lakhovsky.

U

The angle of the plane of the circle with the ground must be approximately 23° ; whether the angle is smaller or larger from 4 to 5° , the avæcum is no longer detected at all. If, instead of VC, we send FV, we get ifs.

If liquid crystals are sprinkled with avæcum, they emit very strong avæcum, long after being out of the beam.

One can find in a plan 28 points, which, when they are well pointed or pierced emit a very powerful avæcum. This arrangement can be made in the ground by making holes with a stick. The avæcum is also very powerful. But with this system of 28 points or 28 holes, we have something else. If we remove or add a point or a hole, it gives nothing. We can plant 28 sticks surmounted by hollow spheres, we still have the preceding properties. You can drill a wooden board and light it with an ordinary electric lamp, the avæcum is very strong. If we light up with a lamp that sends VC or FV, we get ifs. The board put in the dark, there is has no avæcum. In the moonlight, the avæcum is very strong.

Paper 19

July 98

Chapter XIV (continued)

1. L'Avaecum

The forms and combinations of forms possible to obtain favæcum are multiple; we will quote later. But we are going to stop on a rather extraordinary form which, it, allows to generate avæcum but much else. This form is linked to the life of Jules Verne. It is named: Jules Verne Pentacle, Jules Verne Grid or Jules Verne Medal.

The words grid and medal were not chosen at random. Behind all this there is a very deep.

Nonsense has been told about this form, as well as hard-to-verify stories like of this one: Jules Verne would have had it engraved on the back of the armchair in which he spent his days and his nights writing his novels.

We were able to verify the effectiveness of this pentacle (such is the denomination that we will use). The properties of this pentacle change with the place, the hours of the day and the night, the position of the sun and moon. Under certain conditions these properties remain whatever the conditions. mentioned just above. It can be made of paper, metal or even plexi-glass¹. Which is very interesting with this shape made in this material is that it can be used with light moon and then it behaves like a moon dial. Two needles must be used for this; it is preferable that their forms be special. The apparatus thus produced, can according to the orientations very precise in space and at certain hours of the night, depending on the position of the moon during the year, put in transfer with what will be called thereafter the Firthes (or Force Intelligentes obtained by arrangements between Arkhams and Mahkras).

¹ It is possible that reflections and refractions of light rays would have interesting effects. Such is the case whether they are solar or lunar rays! Note also that the pentacle of Jules Verne is linked to the work of Louis Boutard. For example, each hole can be associated with a manipulation order number or even use this shape as a support in an assembly.

I. Complement linked to Jules Verne

It is told in [1] that a group of seven people formed in the 19th century to bring a message to humanity.

First there was a certain Houdlum dit Nollu or Dad. We never knew who he was really. It seems that he was a seer, dowser, magnetizer, healer, hermit, Hercules.

Then Jules Vemes.

Then Thomas Alva Edison: leukemic, condemned, living in a poor family in Ohio as it is told in [1]. He was saved by Dad.

Then Jossel dit Joss: become an orphan, saved by Dad from a shipwreck in a Canadian lake; he became Dad's adopted son. He was passionate about anatomy and cosmography.

Then Jack London: unhappy in his early youth, he followed Dad's advice and became University student. It is said in [1] that it was to test the recipe for strength of health taught by Dad, that J. London traveled the world and became the journalist of the so-called Equipe du "Grand Nord", a team made up of the seven people whose names we give; J. London was considered a writer of the "Great Test" what has again been called the "secret key" of Jules Verne.

Then Commander Sturd: an Irishman who was, it seems, witness to a phenomenon quite extraordinary. He was with Dad in the far north and there was an aurora borealis.

Simultaneously, a purple coloring appeared on Dad's X-shaped chest.

coloration was slightly changeable. If we test this phenomenon, we realize that when we pass by magenta, it brings an effect on the brain of the one on whom the phenomenon occurs.

Then Roald Amundsen (he went to the South Pole) who, it seems, met Dad for the first time at Nome September 6, 1906, so one year after the death of Jules Verne.

Then Doctor Clodel, then Tyrnu providentially saved by Dad during an accident on the way of iron. Tyrnu had a son who remained, out of gratitude and on the advice of his father, a servant devoted to Dad.

Then Alfred Renoux, who was considered the eighth member of the so-called "Equipe du Great North" or even "Those of the Great Test".

The seven are:

- Jules Verne

© EÜREECALL

Dad

- **Jossel**
- **Jack London**
- **Sturd**
- **Roald Amundsen**
- **Thomas Edison**

Sturd, Jossel are perhaps pseudonyms? And the others may have been placed there so that sets up a whole different story. In this we must not forget that they sailed a lot, therefore water is important; the same applies to magnetic and gravitational fields.

It seems that it was Dad who contacted Jules Vernes; the others gradually followed. In none of their works or biographies (of Jules Verne and Jack London) there is no question of this mysterious group of seven. Chotard tried to find coded messages in the works of Jules Verne and Jack London. But then he manipulated the numbers attached to dates, places, which is absolutely extravagant; it fell into the trend taken by many occultists who make numbers say anything. About the numbers three cases can be to present.

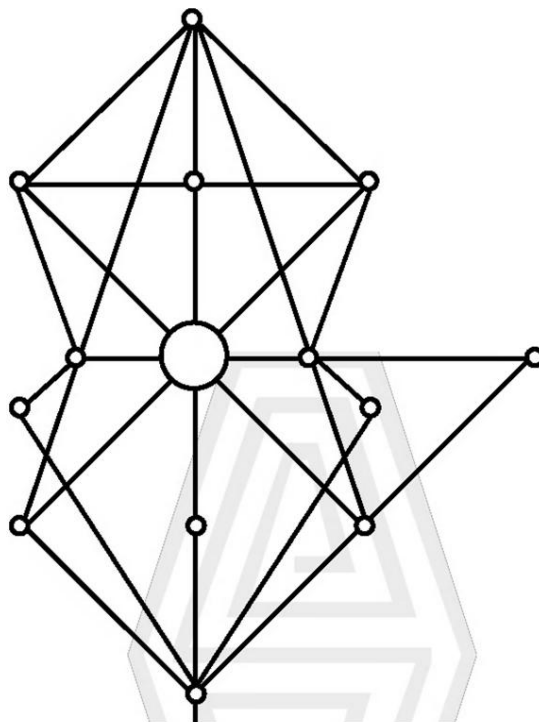

- **or we make them say anything!**
- **or they correspond in certain cases to very precise facts**
- **or they serve as an inspiration to whoever uses them for any other field. Numbers would be the equivalent of a plane geometric structure where sequences of straight segments and curves can give operability to manipulations on shapes. For example, some of these broken lines make it possible to lift grids when they have been drawn in a plan. It is enough even to have them present in mind. So the numbers would be the equivalent arithmetic of this geometric scheme. To the multiplicity of shapes, positions, lines, one can associate the multiplicity of properties of numbers. While it is necessary to draw the curves, the numbers, according to their recursive law of generation, contain all their properties; it suffices only to extricate them from them. Numbers are a unit one breaks to extract wealth from it. Curves are a construction, element by element. It is very important to be aware of the approach: the approach is the Way of doctrine of the Tao. When one places oneself in the other C. of C., it is the Way which is**

© EÜRECALL

fundamental ; everything is built on the Way; the Way supports the story. There is no longer a goal, it is a story in which one immerses oneself. We can be in Dd with this story, or in equimsey.

One can also associate arithmetic approach and geometric approach. By the way Chotard presents broken lines connecting holes of the pentacle and to these holes correspond numbers (this which he calls the "Encrypted Medal"). This is a very special case of what we were talking about more above and which he did not explain in depth, because he focused on considerations of the type "simplistic esotericism".

We give here a single plot obtained by Renoux and Chotard and taken from the pentacle.

From 1965 to 1967 four works by Chotard [1] were published, the first entitled as we have seen:

"As it was intended" (edited 4-28-1961).

Others :

- "Jules Verne's Great Secret Test" (edited 14-12-1962)
- "Jules Verne divine magician" (edited 4-9-1964)
- "From Jules Verne to Extraterrestrials" (edited 20-12-1967)

The first book (in the order of publication) reproduced in full a manuscript entrusted by Renoux in Chotard. It has been said that Renoux said "It's all in this book".

© EUREECALL

The other works are only fragments of commented texts. Chotard did not follow the instructions from Renoux who had indicated to him as the title of the second book "Tel que c'tait planned" with the subtitle: "Sparks of death. Sparks of love". Chotard completed his publications in publishing under his own name a 32-page brochure: "How Jules Verne comes to trace in space and time the destiny of man with "Appolo" 8 and the "Soyuz" 4 and 5? (1968-1969). This booklet still contains interesting fragments of Renoux's letters.

In this booklet the point of view used by Chotard is a bit simplistic. He uses, without the to know, of certain events which he connects between them by the pentacle of Jules Verne; his system looks a bit like handling a crystal ball but it is much less rich. In the first three books published, there was this pentacle referred to as the "Cypher Medal" with a fairly brief study of figures and numbers. In addition there was a study on a figure named V (because that was its shape on the pentacle) of the first 5 cycles (the other 3 were jealously guarded by Renoux) and a curious map of Alaska on which are divided into various locations of crosses and circles.

We can work on this map; we realize that she is not too eccentric although she does not have exactly the shape of Alaska. If we plant pins vertically in places where there are cross and that we make holes in the places where there are circles and that we place above this card the pentacle it leaves a very powerful avæcum; we are on the other hand in transfer with these places marked with crosses and circles. Chotard claimed that this pentacle, suitably ciphered, "contained all natural laws encrypted in some way"? This doesn't mean much. He remains that pentacle acts strongly on the psyche of the one who uses it.

A Renoux had previously published two brochures

- The Great State of Balance (edited 1-3-1938)
- Lesquels s'amusement (published in 1957) and his book
- "Around the World on a Champion of the Seas².

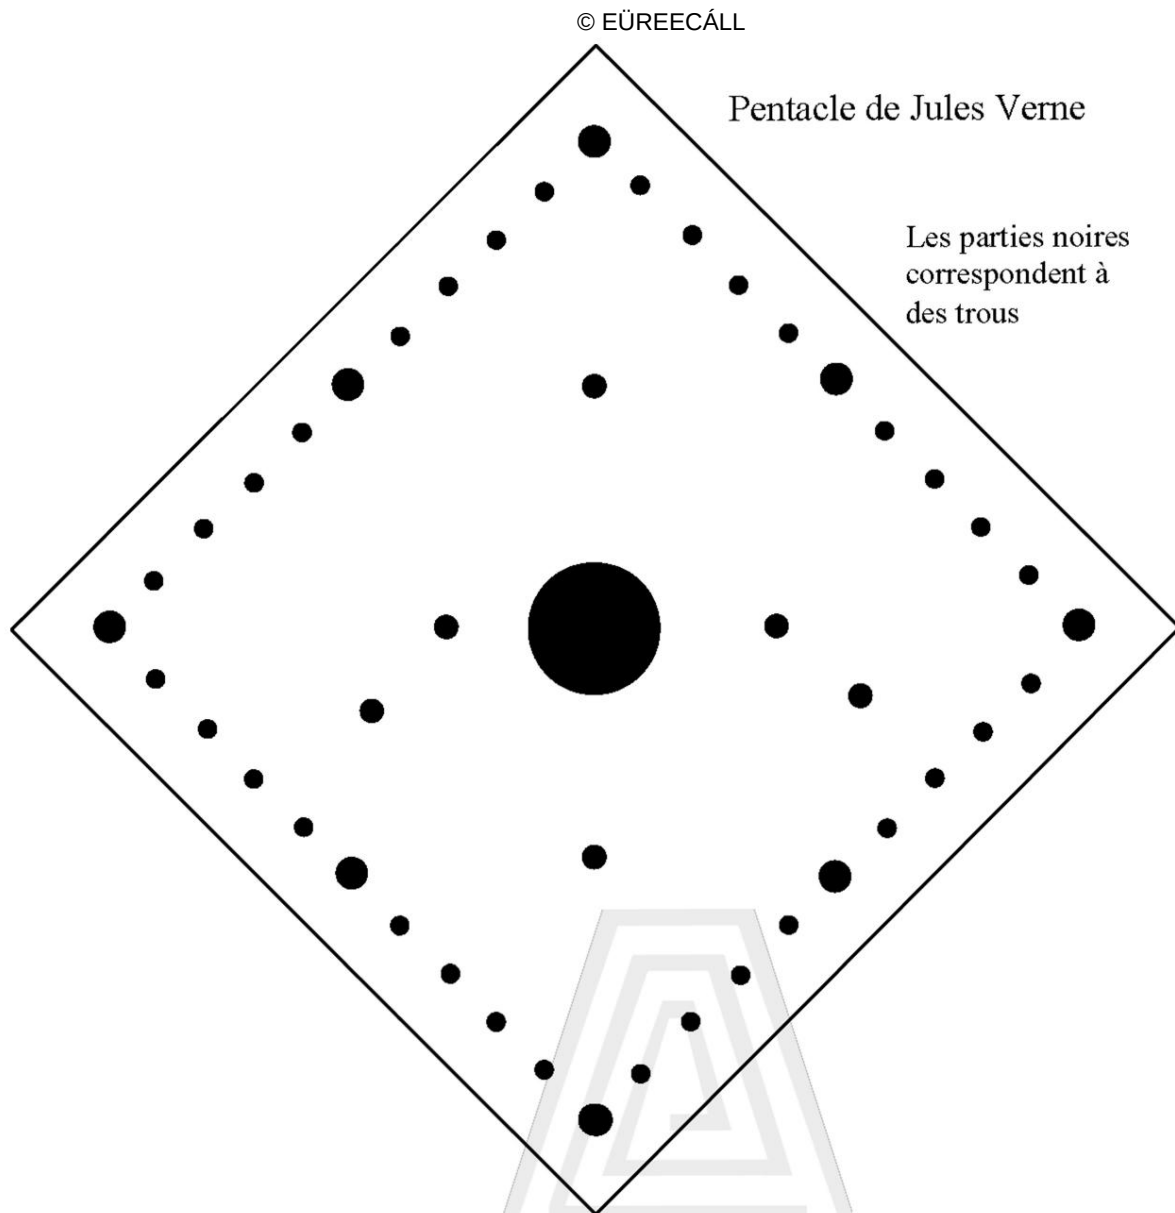

² We were able to obtain this information from R. Rouaud who went to visit Renoux several times in Nantes. He gave R. Rouaud advice such as "Measure with a millimeter ruler the photograph of the cover of the booklet entitled: "Le Grand Etat d'Equilibre", which he also wrote in the GEd'E, which says "I helped". Measure on the picture the base of the trapeze (the picture showed a trapeze artist sitting on his trapeze), the length of the ropes, the top of the trapeze and all possible details. Take the diagonals and see where they intersect. Measure the height of the letters of the

© EUREECALL

To make known to the public the first brochure that only we could have in our hands, we refer the reader to the review ARK' ALL Communications. We will not dwell more on this subject, this would take us too far.

If we pay enough attention to the works of Chotard, and in this area we must be very careful to properly separate "the wheat from the chaff" (we can also spend a lot of time there!), we realizes that four colors are involved: blue, purple, green, yellow. If we draw a rectangle and that we put vertical bands colored in these four colors (like a flag), avecum is detected. It is not in transfer with the pentacle of Jules Verne, but if we put it above, one detects a very powerful avæcum. *7

title, their spacing. Count the number of letters, the number of syllables; for example: The Grand State of Balance, ie 7 syllables and 21 letters.

Let's go back to the curves drawn in a plane for multiple uses. These are most often time-dependent forms. They are linked to the Obs. By looking at them or by rethinking in the brain if they weren't imprinted on a plane, EObs creates eifs in it or even everything that has been described. They can intervene at several levels of equivalence. He is at note that this concept of equivalence levels may vary over the lifetime of EObs, i.e. say that as he invests in new concepts, the importance of the levels of equivalence changes. Other concepts become more fundamental. This comes from the fact 3

3 See 1st level course (9 booklets).

© EUREECALL

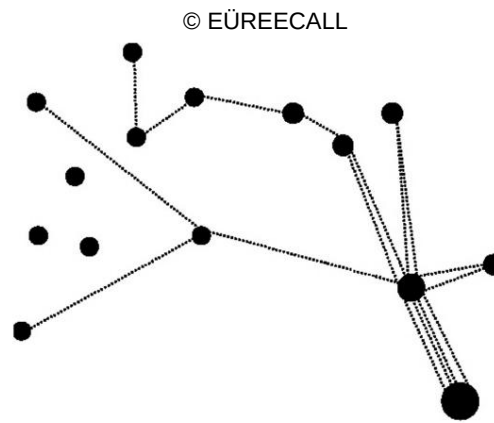

that the Obs modifies a neighborhood in the coherence radius (R. of C.) or the coherence field (C. of C.) which he throws. This modification can extend to everything that is in the field of coherence, thus the researchers in the same field who follow it will find themselves in the state that the Obs has put in place thanks to the local modification of the R. of C.. In the R. of C. the modification is transmitted by the Voiloc of the Obs or location paths attached to systems that are in the R. of C.

launched by the Obs.

Such tracings, if one runs through them with the eyes, give high C. of T., their escape... and even the avecum. They also act at the cerebral level and that is the most important thing. You don't have to do any journey. You can also use the holes that are on the sides of the square that is the pentacle. But this pentacle makes it possible to obtain much more than all that. We can by routes in very specific places have access to the Firthes (a concept that we will see later), direct ideas.

Now let's look at a totally different story that has been told many times in the books about UFOs This is what happened to Bamey and Betty Hill on September 19 1961. We will not describe the event; it can be found in many books. Say under hypnosis (the two protagonists no longer remembering the event) Betty Hill told that when she and her husband entered the UFO, little beings had shown them a flat card and thin on a screen that gave the impression of depth; its dimension was 1 meter by 60 centimeters and you could see a lot of stars among which Betty only retained the most visible, those that were connected by lines. She also remembers a small triangle on the left side of the screen. In a UFO phenomenon, one should not describe a story at all as in the C. of C. usual. We have seen⁴ that it is the trace in our rational C. de C. of an island of incoherence. This trace can also be presented as a macron. Nothing may have happened to inside the car or in the UFO, and that regression under hypnosis is part of the phenomenon. The unconsciousness of which they have the sensation in memory may be only an effect of the islet of inconsistency. Let's come to the map of a starry sky seen on the screen. We could say that she could not draw very little compared to what she is supposed to have seen. But in the phenomenon there is also this impossibility of reproducing everything and in what she has reproduced there is enough to suggest a shape with properties that have nothing to do with a starry sky.

⁴ See 1st level course.

Map of Betty Hill

If this shape is made in a wooden or metal plate and the blackheads are drilled in respecting the diameters of the holes, we realize that it is a transmitter of avæcum and at the same time a form related to the $\mathcal{A}\mathcal{E}$. We are much closer to a form like the pentacle of Jules Verne than a starry sky. We thus see that in certain cases of the UFO phenomenon, it is suggested ways as in dreams.

II. Complements about Vavæcum

The field is so vast that we see ourselves obliged to talk again about the forms that emit avæcum, forms which are reservoirs of it.

The avæcum strangely resembles the "formative forces" of Rudolf Steiner. That's not all does this because Steiner's thought was not expressed in the C. of C. which was proper to him, ie the other C. of C.. To be able to correctly express the formative forces it is naturally necessary consider the avæcum but also fields of trajectories then what we have named the Firthes and much more.

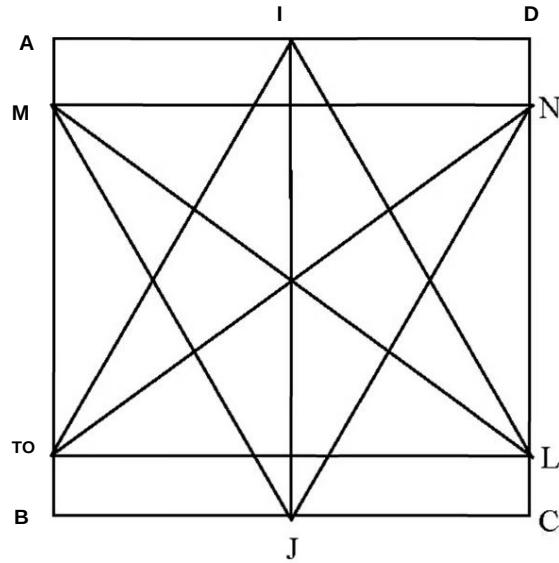

Note that the foam of the waves has a fractal structure. And by taking up the process that allowed to make the word avæcum (before foam), we can place LD and LC then after LA and LB as at the "interface" between the avæcum and the eifs. The eifs would therefore correspond to the structure foam fractal.

Exercise :

Let us point out a form which allows to have a fairly powerful avæcum: We consider a square ABCD in which we draw 2 inscribed equilateral triangles, namely IKL and MJN. This is used to plot the non-regular hexagon MJNKIL.

So, if we cut a square piece of wood such as

© EUREECALL

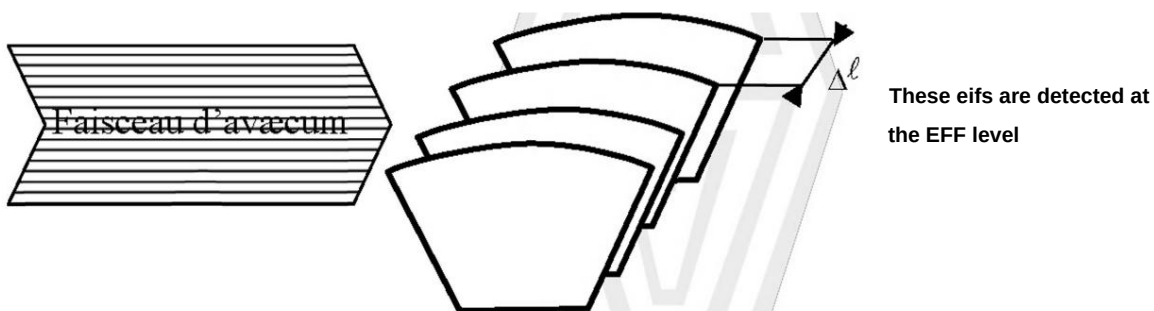

,ABCD and that we draw only the non-regular star hexagon MJNKIL then that we put this square on slice BC, vertical, avecum is detected on either side of the plaque; the beam has for axis the axis of the system which is horizontal. The cross-section of the beam is smaller than the surface of the square.

The non-regular star hexagon resembles the shape that gives the FFV dynamism.

Exercise :

If we send a beam of avæcum on a capacitor with parallel blades in the following way, that is to say that the angle between the plane of the blades and the beam is zero.

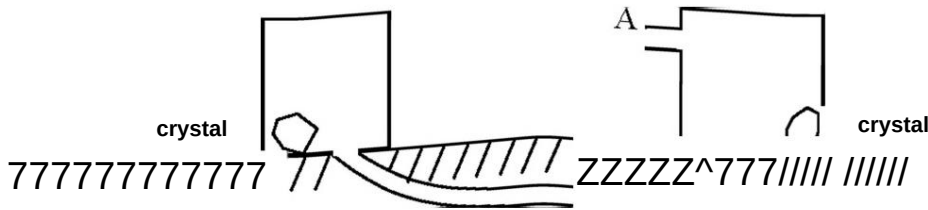

Depending on the spacing M between the blades, different eifs are obtained.

Exercise :

Consider two enclosures containing crystals and linked by an underground channel. The crystal can very well not be pruned. By this process one has a strong bundle of avæcum which behaves like if it came out of the conduit indicated by A on the diagram.

© EOREECALL

Exercise :

You can load certain liquids into avæcum by a simple process: you just have to put the liquid in a colorless glass container and to cover this container with a glass whose tin is towards ! ,outside. By leaving this assembly outside, because the liquid is especially charged in sunlight, does not not discharge at night whether there is the moon or not, we see that the liquid and its surroundings are impregnated with avæcum.

////// If this liquid is not harmful to living beings and if it is swallowed in small

quantities by this living being, the latter after absorption often emits C fields.
of T. and their escape as well as VC, LD, FV and LC.

Exercise :

We report this assembly because we can see that in the field presented here, it is always necessary to do note: let us therefore consider a liquid which can be charged with avæcum by this process. Let's make them two following assemblies: two colorless glass containers of the same height, of different sections and both covered with a mirror.

[illegible]

Let's put the same liquid in each one at the same height. We will observe that the one on the right will quickly charge in avæcum while the one on the left does not charge. We should raise the liquid level. There is a relationship, depending on the liquid, surface-height. There may be variations in this ratio according to the place and even better the moment.

© EUREKALL

“Let us learn to dream, gentlemen,

and

maybe then we will see the truth”

Auguste Kékulé von Stradonitz

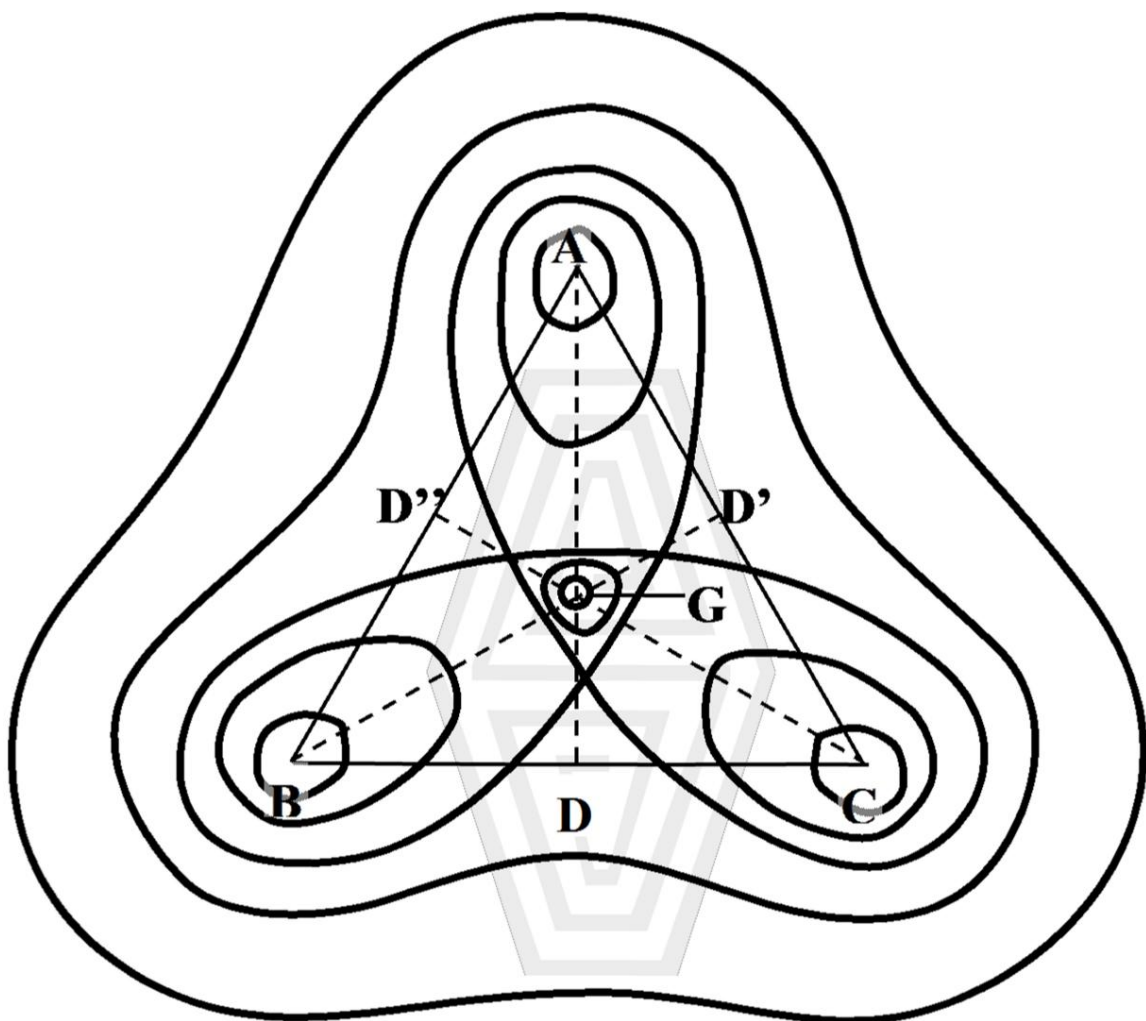

1829-1896, born in Darmstadt, German chemist, pupil of Liebig, Dumas and Gerhardt. In 1858 he stated the principle of the tetravalence of carbon, also noting its property of forming chains of carbon atoms. He postulated the existence of a group of atoms present in certain aromatic compounds such as benzene (a group that has since been called the benzene nucleus), the structure of which he attempted to explain by a hexagonal expanded formula (known as Kekule). These ideas were applied to other aromatic nuclei by Erlenmeyer and Graebe. Kékulé's work has enabled chemists to understand the meaning of formulas developed in organic chemistry; they are the basis of the sudden development of the synthetic organic industry in the world, and particularly in Germany (industrial synthesis of alizarin in 1868).

Exercise :

There is a curve which makes it possible to have a vacuum: for that let us consider an equilateral triangle ABC, G its center of gravity and has the radius of the circle circumscribed to this triangle. Let M be a point of plane, we consider the scalar field $f(M) = \frac{1}{3}(MA^2 + MB^2 + MC^2)$. Let D be the foot of the height lowered from A to BC. Let DM = h. If we take M on the height AD, we have

$$f(M) = f(DM) = f(h) = \frac{1}{3}(MA^2 + MB^2 + MC^2) = \frac{1}{3}(h^2 + 3a^2)$$

MA, MB, MC are the distances from M to A, B, C respectively.

© EÜRECALL

The curve $f(h)$ plotted as a function of h has a maximum and a minimum. Let $h = a$ the abscissa of maximum. For $f(M) > f(a)$ the corresponding curves are formed by three loops containing each of the vertices of the triangle. For $f(G) < f(M) < f(a)$ we provide ovals, one surrounding G and the other outside. For $f(M)$, a single exterior oval whose shape tends towards that of a circle. Some of these ovals may have double points but only located on the axes of symmetry.

To detect the avæcum, the sides of the equilateral triangle must not be drawn. It's necessary point 2 vertices, drill the third and point the center of gravity. There is no need to impose $NfSf$.

If several curves are drawn, even if they belong to different types, (we have seen that there had 3 types) one amplifies the avæcum.

If we draw two families of curves, one connected to the equilateral triangle ABC and the other to another equilateral triangle in the same plane, quite close to each other, we no longer detect an avæcum even piercing other peaks⁶.

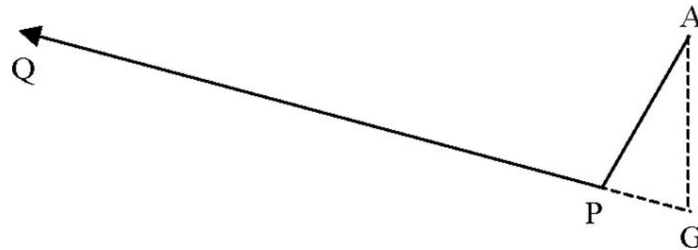

Let's go back to the four yews. It has been reported that they can be placed in pairs LD-LA and LC-LB male-female. We can by an appropriate choice of shapes apply 3 of them to the points A , B , C or even a couple in A or B or C and the other two yews respectively on each of the two other vertices of the equilateral triangle. This gives amazing possibilities. Transformations of this type are envisaged in Tantrism (the true and not what is presented in the West in multiple works where the translators and writers were content to compile most often texts and works too hastily without understanding their deep meaning. It is possible, moreover, that the original works contain only a superficial study, which for those who would use, would only find reminders there). We will therefore not find in the original works descriptions attached to an obvious consistency.

The fact of making a hole in a vertex of the equilateral triangle, for example in A , imposes the Nf . Thereby the Nf is on the half-line DA and the Sf on the half-line $,AD$. You can draw contour lines on a circular or square wooden plate; the center of symmetry G of the figure being coincident with that of the circle or the square. The latter will not be pierced, simply pierce the hole in A on

We have the polarity + outside the largest level line and - inside even if it contains others.

© EÜREECALL

vertices of the equilateral triangle; it must cross the plate. We simply point to the center of the figure is G. We will use an articulated needle of length $4AG$ fixed in A with an articulation at P, such that $AP = AG$ and at end Q such that $PQ = 3AG$. The needle will be used to locate an eif at EFF level, differentiated spectrum. G, P, Q must always be aligned.

The contours of this field are very important. They each correspond to a field value. Constant values of other fields, in astronomy or related fields to the shapes of the leaves of plants had already been noticed, respectively by Ravatin and La Liver. We can also use this scalar field in another way: we therefore start from a triangle equilateral ABC, we do not pierce any vertex and we draw the level lines of the field

$f(M) =$ • It turns out that these level lines are "revealers". Naturally

they all exist in potency by the formula but a few plotted reveal. They are "revealers" for the H Obs, in particular they reveal the possibility that human beings who are in the C. of C. of Obs can be considered as equivalent to Obs, then, that these human beings can also use contour lines as indicators. A certain level line that surrounds others already in place, makes it possible to produce the spreading of the multiplicity, that is to say the possibility that the Obs has of placing in its C. of C. other equivalent human beings to him and all beings living outside of him; and to suppose this property true for all beings living.

We could have found other fields. Moreover the field $f(\tilde{C}TvI) = \frac{1}{1} + \tilde{N}1B$ is $\wedge$ 'study plus

simple as the one we have just presented. The fields of interest are those of the form

$f(M) = Y$ where the A_i are the vertices of a regular convex polygon.
 $i=1 \dots n$

⁷ "Revelator": notion which will be seen later.

Their general study is very complicated and especially the drawing of the level lines. They send a *avæcum* above the plane which is very powerful. We can plot the orthogonal trajectories of these curves. They also have interesting properties in the field we are developing. The fields given by the same formula but for which the points A_i are not placed at the vertices of regular polygons are less interesting. The field $f(M) = r/r^2$ whose lines of level are the Cassini ovals with the Bernoulli lemniscate as a particular curve, which corresponds to the flight of markers in the case of decalars or cumulo-decalars, is also less interesting. On the other hand, in the case of certain constellations, a field of the form

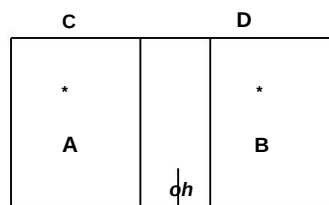

$$f(M) = \sum_{i=1}^n M A_i, \text{ where the } A_i \text{ correspond to each star of the constellation, is very interesting. He}$$

must draw the constellation in a plan respecting the best proportions. For this we can use a constellation atlas like [2] (in this particular case if you want to use simultaneously several constellations, we must be careful that they are not all at the same same scale and that they must be reduced to a common scale). It is necessary to use the constellations of the elders; these are the ones that have properties. You can also use fields that are linked to points in space, but in this case if we limit ourselves for example to polyhedrons and especially to Platonic solids, drawing level lines is very complicated. You need computers; by against the *avæcum* is extremely powerful. In the particular case where the points A_j are in a plane, we can draw the trajectories orthogonal to the level lines. They too, when we trace several have very interesting properties. It is not necessary to draw on the same figure trajectories orthogonal and level lines. Almost nothing comes out. Orthogonal trajectories do not must not have the segments of the polygons present, only the vertices. We can not not develop in more detail the considerations on the eifs, ifs, *avæcum*, components of the *avæcum*, pavs, states, atmospheres, vital fields, etc. which can be detected on the families of curves. We can avoid drawing certain level lines in the case of fields $f(M) = \sum_{i=1}^n$

where the A_i are the vertices of the regular polygons or dodecahedra. First, we can only plot a few lines, the more one draws the more powerful the *avæcum*; the idea is to seek to have the form and field contour lines. To do this, small crystals can be added at points A_i . For some, a very powerful *avæcum* is obtained because everything forms as if the lines of level were apparent. For plane figures, if the vertices of the polygon are pointed on a

sheet of paper, level lines are not detected outside the edges of the sheet. In the case of polyhedra, the level surfaces are detected in all space, the polyhedron must have its faces; we no longer detect anything if there are only the edges. In the case of the Platonic polyhedra, they also become hard cores. In the particular case of beaded dodecahedra (with faces holes) if a person wears one on their forehead and another person, even very remote wears another, of the same type, also at the level of her forehead, and that moreover, the two people think of each other, then a transfer takes place and the level surfaces detect each other around each dodecahedron. They can be used to contain information that will pass from one person to another. This does not mean that the beaded dodecahedra were used like that or only like this.

Let's go back to the launch of the C. de C.; either A this launch, or B which corresponds to the dilution of the obs in the C. of C. Of all this the obs only perceives an echo, either C, which it filters, or D.

Let's put this on a T AG system, that is:

$\wedge bs$

It should be noted that in this construction no time intervenes, there is no before or according to. Plating on the TAG system requires cells C and D to be in place, so does the separation between the two, likewise the locations in these cells, symmetrical, A and B. The Obs is stuck on the separation corridor (the ancients would have said that the Man balances). In reality there is only one obs, everything that will come after, and there will be an after, is the consequence of this tackle on the TAG system. In this tackle the obs throws his C. of C. which corresponds to the position A and places itself in it, which corresponds to the position in B but it only gets an echo from it either cell C, which it filters (rearranges), or cell D.

This will create an atmosphere, which will be the spread of multiplicity (by abbreviation: étamul).

Then here comes a nuance in the cerebral process of awareness of the etamul.

By etamul:

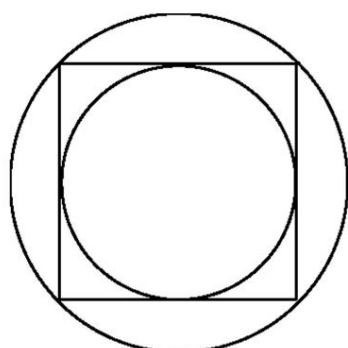

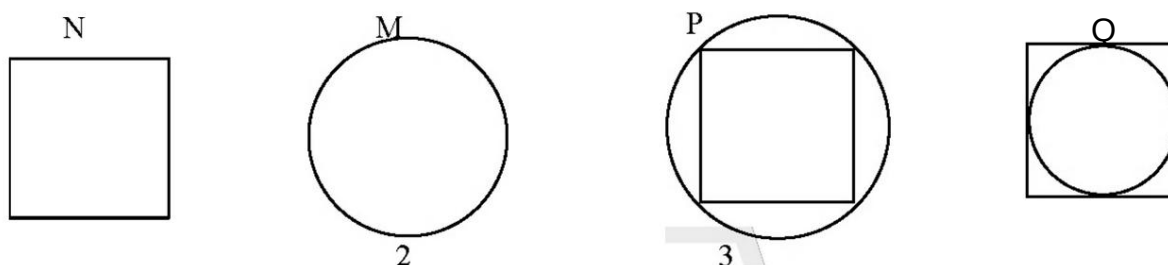

- either only each human being is exterior

- either each human being is external and enjoys his personal etamul, which makes that the Obs tacitly admits that the others are equivalent to it.

In the usual C. de C. it is tacitly admitted, although we are absolutely unaware of this Steps. In the other C. de C. we have the awareness of this whole process but it may be that there are R. de C. in which we only have the first part of the alternative. let's see it second part of the alternative: the obs (O) can be considered as creating the individual I but according to this second part, I is equivalent to the Obs therefore creates the Obs. It would seem that O is not complete without I.

Exercise :

Consider the following model: a circle M and a square N such that if N is inscribed in M, this gives a form P and the permutation between M and N, a form Q.

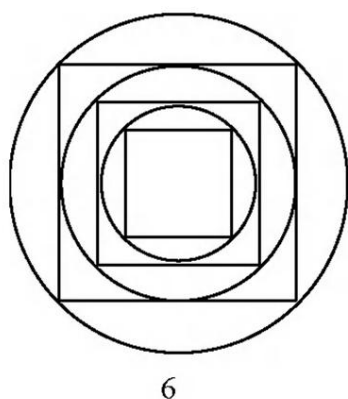

Consider M and N as primers and P and Q as progenitors such that $M|P = Q$ and $N|Q = P$. In P and Q, M and N have positions relative so that P and Q are not stable as a form drawn above (1, 2, 3 and 4) but, the existence of M and N in P and Q and the posed equimseys give us the following shapes, drawn opposite (numbered 5 and 6).

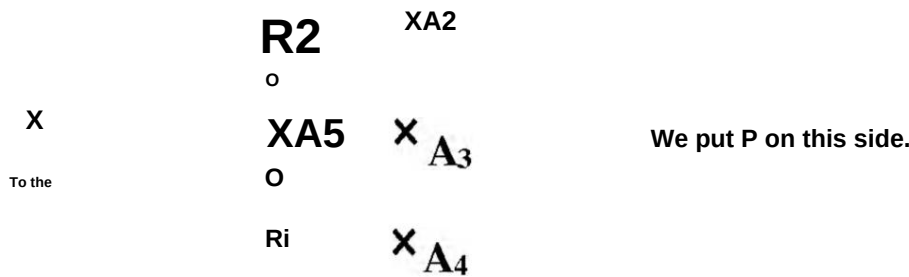

The equimsey makes it possible to account for the fact that the forms M and N assembled in forms P and Q, are not complete and that they complete indefinitely.

But it is a question of making primers and equimseys.

a) check that to perform the primer between M and P it is sufficient to place P on a red carpet pierced with 5 holes, and 2 small circles are placed as below. The holes are A!, A2, A3, A4, As, and small circles B!, B2

© EURECALL

It is best to center the small circles.

- b) Check that to make the primer between N and Q just place Q on a pale yellow carpet pierced 2 holes and 5 small circles, placed as above.

Just swap circles and holes from the previous figure.

- c) Check that the M|P and N|Q equimseys can be made by placing the assemblies a) and b) side by side and interposing between them a piece of graphite. Above assembly c) one detects on this that there would be by continuing indefinitely, such is the diagram of the figure marked 6.

Remark :

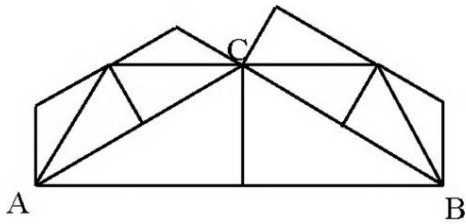

Let's match the Obs O to M and an individual I in the coherence field of O, to N. The model used accounts for the fact that O creates I but which contains O which creates I etc. That's not all quite the representation in usual thought; you can insert it if you want, but it stays in this case, unimportant mind game.

Exercise :

Another model can be considered, still for the last part of the previous alternative.

Consider an isosceles triangle with base AB and two smaller sides. let's build two isosceles triangles similar to the first and so on. The outer contours have at the limit of building a fractal structure. Thus, by this process, the different stages of construction of a fractal object studied in 1938 by the mathematician Paul Lévy [3],

We will take for example $BAC = 30^\circ$ or an angle less than 30° . Angles greater than 30° not allow to obtain a fractal object.

At Obs O let us correspond to the triangle ACB; to human beings I! and 12, in his representation it will match the first two triangles constructed on sides AC and BC but like them, are equivalent to O in function of O in their C. of C. and this by étamul.

Note 1: _____

The two models considered can also be used to account for the approach brain of Lobs O because in reality, it is he who realizes his type of reasoning and realizes his status. Etamul is for others as well as for oneself.

Other models are possible which involve only two stages. The importance of all these patterns is to have a grasp of cerebral gait.

Note 2: _____

If we come back to the level lines, we said that they are revealers. We can put the brain of a human being in transfer with a set of level lines. If this transfer is in place, or if need be by adding an exterior line to the given set, we will increase its sensitivity and also the person concerned will increase his areas of perception. It is good to drill in the center of gravity G of the equilateral triangle so as not to have equivalence levels that could lead to unintended effects. We can put a witness in the center; the baton should not be left for too long. All this development about the field $f(M)$ envisaged previously constitutes variations multiples on a form.

Exercise : _____

Avæcum can be obtained from stakes planted in the ground. The stakes have the same length and protrude the same length from the floor. They are in the same plane and separated by distances satisfying several possible sequences of values. Their ensemble emits day and night. We can even engrave on a glass plate, parallel vertical lines, unevenly spaced from each other, but the intervals still satisfying very precise sequences of numbers. If we lit from behind or even better in grazing incidence, the avæcum is very powerful. If we do a orthogonal affinity on the figure engraved on the glass, the ratio $k < 1$, it is even stronger. If we put

two such arrays of lines on 2 glass plates so that their directions are perpendicular, there is no more avæcum; the closer the angle is to 0° , the more avæcum is detected. Let us recall that when the angle is 90° , it is as in the cases previously indicated, the avæcum is not even detected at the exit of the barrel or more generally of the transmitter.

Exercise :

Consider a closed box. Let's drill a small hole in one of the faces. The box becomes a weak transmitter of avæcum. But if we paint the inside matte black and it's still drilled from a small hole, check that it becomes a powerful emitter of avæcum. And this regardless of its form. (If the black is matte, the shape takes on an ext).

Remark :

Now we find here the black body which intervenes in the laws of the emission of radiation. So any black body emits avæcum. Moreover if in the black body, we put a quartz crystal, not too much big compared to the volume of the box, we have emission of avæcum which is amplified. Obviously we have detected from the avæcum without any black body presence. But every body has more or least one blackbody character¹⁰.

If, for example, a piece of polished metal (body perfectly reflective) or a fragment of frosted porcelain (perfectly diffusing body) bearing spots of platinum black, these spots emit more light than the rest of the body and stand out brightly against a dark background. If we test, we discover that they emit avæcum. By against sunspots do not emit avæcum. The black body has the character of what further we will call: hard core. Forms that are hard nuclei emit over time more and more avæcum.

If we have in the interior of the black body, plates with holes or not, in certain arrangements, there will be no more avæcum. Some signs drawn externally on the surface may increase

⁸ The expression used in black body physics is poorly chosen; it simply means that at ordinary temperature, the black body, which neither diffuses nor reflects any portion of the light which illuminates it, appears black - like lampblack or like the inside of an oven. states in physics: the spectral brightness of a black body is independent of the direction considered, and of the nature of the walls. This is why we speak of blackbody emission and not blackbody emission.

¹⁰ The brightness of any body, for any wavelength, is always lower than that of the black body at the same temperature. That is, of various bodies at the same temperature, it is the black body that emits the most energy.

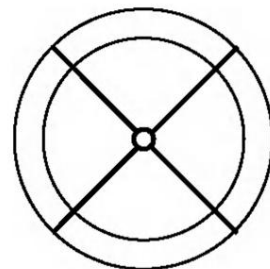

© EUREECALL

ravaecum. We can even provoke a Dd between its interior and its exterior. We see that the avæcum is not identical to the energy, first it is not localized, then one can make a black body which does not emit avæcum.

A flame that contains a metallic vapor emits a spectrum of lines by incandescence. By example with sodium vapor, the flame is yellow and emits the double D line: the vapors of sodium contained in the flame must be absorbent for this line. If we cross the flame by the light rays from an electric arc, and if they are then received on the slit of a spectroscopy, it should be observed that the radiations corresponding to the D line which were in the arc spectra were absorbed; they have moreover been replaced by the radiation emitted by the flame. The brilliance of the flame is certainly lower than that of the black body at the flame temperature, approximately 1800°; the brilliance of the arc is much higher, of the order of that of the black body at 3500°: the lines D consequently stand out in dark against the brilliant background of the continuous spectrum. This is called the reversal of the lines; we know that it is by this phenomenon that one explains, since Kirchhoff, the existence of the black lines of the solar spectrum. Right here the avæcum is still detected in the black lines and is located in a three-dimensional neighborhood spectrum [4],

The avæcum can be obtained by surrounding coils: for example a rotating engraved cylinder around its axis. The avæcum will be all the more powerful as the speed of rotation will be high.

Note that jade amplifies the avæcum (this varies according to the color of the jade). We can amplify it also by a mounting, at the exit of the guns, in cross of Saint-André not encircled, or encircled, which is even more powerful. You can also use a small square mesh fence (hexagonal, this would not give the expected effect) or rectangular (for these dimensions are more interesting than others).

x

Certain religious objects and motifs emit avæcum: for example the cross of Saint-Maur believed to be from the 9th century. It is in the abbey of Saint Maur; this building is on the edges of

the Loire, near Angers¹¹. It was occupied by eight Assumptionist religious. Now they are gone. The cross, which must have been slightly pattée, bears, for all ornamentation, interlacing mixtilignes. The drawing in the center protrudes 3 to 4 cm; elsewhere the notch does not exceed 1 cm. The total height of the cross is 2.38 m. ; the arms are unequal; the one on the right is 0.88 m and the one on the left 0.65 m. This is important because Ravatin and Dupré realized from marks made on an astrolabe made by Dupré, (which is an extension of a simpler one made by Don Néroman), that at the intersections on the sphere of the fixes of the ecliptic and of the polar circle we could match a cross with unequal arms; on the other hand the ratio of the lengths of the two arm is weaker than for the cross of Saint-Maur.

The cross of Saint-Maur rests on a foundation of stones, several of which are decorated with drawings. From resemblances have been detected to the stone cross at Carew, Pembrokeshire, in England and the carved cross of Abellemno in Scotland. Drawings similar to those of this cross were found on sticks in the Dublin museum. These remarks were used to make it a dating; it is therefore not certain.

In the center is an interlacing which is interesting because it emits avæcum and avæcum quite powerful. We give a reproduction made on site by R. de Montercy. There must be voids for the avæcum to be detected. If the patterns on the arms of the cross are openwork, the avæcum is very strong. By slightly modifying the central drawing, we can while keeping the avæcum and even amplifying it a little, detect the FFV. The cross of Saint-Maur as it is, embedded in a wall of an old chapel of the abbey does not emit an avæcum.

¹¹ Abbey of Saint-Maur de Glanfeuil. La Thoureil 49350 Gennes. For all information write to this address.

© EÜRECALL

Complement :

Another example of a shape that can emit avæcum but only under certain conditions can be found in !,following story:

A few centuries ago, lived in the region of Trace, in northern Greece, a monk, hermit, named Father Demetrios. This man was famous all around, because he lived alone in an inhospitable region, according to travellers, other monks and all the villagers;

moreover Demetrios seemed to live in the midst of great abundance; this was manifested in particular because he offered a lot of food as a sign of welcome to his visitors.

One day a traveler passing through the Trace region entered the humble abode of Demetrios; he observed on the interior part of the front door a cross; it was adorned with symbols and initials. The traveler asked Aba Demetrios what its meaning was; the hermit referred to a singular story which was kept in the library of a monastery Greek.

One night, Demetrios had a strange dream: an angel appeared to him surrounded by a light supernatural which made him resplendent. He spoke to him: "For the life you lead, heaven reward. If you hang this cross on the door of your house, you will no longer be tempted by the devil. Never again will you make bread and the fires of evil will be repelled". And the angel drew with his hand a cross surrounded by symbols and initials that Demetrios kept in memory with all the details possible and that he reproduced on waking.

Then he hung the cross on the door of his house, where the traveler discovered it, and he activated it with a special ritual. From that moment Demetrios fell into a state of bliss, tranquility absolute peace. His life was blessed with an abundance of food.¹⁹ He reaped a hundred times more than he should have with what he sowed and his reserves, instead of diminishing, seemed to increase.

The traveler shared the monk's meal and got ready to spend the night at his house. The next morning, when he woke up, he saw that the monk was dead, but on his face he had kept the same expression of inner peace.

The monks of the nearest monastery were notified; they came to bury the remains of the hermit and took away the Cross, the story of which was told to them by the traveller.

The miraculous power of the Cross was confirmed when, ten days after it was placed on the door of the humble monastery, it received an important donation from distant Russia: a gold crown encrusted with diamonds and rubies, which the Tsar gave because it had belonged to his father, a great devotee of Saint George and also of the fact that the monastery was dedicated to this saint. 12

12 In the case of the Curé of Ars, localizations of wheat were made several times as well as localizations of entities with which he conversed; witnesses make seen and heard a dialogue.

© EÜREECALL

The original "Cross of the Gate" remained there until today; she is still there and continues to bring in abundance his gifts of prosperity, bliss among the monks. The reputation of the place went increasing in such a way that in the century in which this story began, an Athenian antiquary visiting the monastery stayed there for some time. Having also been able to benefit from the benefits of Cross, he asked permission from the monks to reproduce it. They agreed and decided that one of the monks in the library would give the Athenian in question a parchment copy. There is has a ritual to activate this form; it is not known exactly whether the details of this ritual were transmitted by the monks at the antique shop. Finally, you should know that the antique dealer having taken it to Athens, he lived the rest of his life in great material prosperity and spiritual calm to the point that his house was known throughout Athens as "the House of the Cross of the Miraculous Gate".

In this way the gift of Heaven given to a holy hermit to reward him for his life as a saint by through the miraculous appearance of the angel, became accessible to other men.

Advice was given for using the Cross with indications for the ritual; we do not know if this is the original ritual.

The cross should be hung on the main door of the house or office so that it either face inward. This is correct because if we test we see immediately that it is in a vertical position which is the most effective. If it is a field, it is advisable to place it on a palisade closing the field. Avoid placing it in a noisy or agitated place.

You can make various offerings of flowers to this Cross, light candles (white), burn incense. It may be noticed that it falls off sometimes, its gloss shows up differently, she may not appear in photos taken of her. This cross, when we pray facing it, or if a ritual is performed takes on interesting properties.

She takes an ext, then emits avæcum as well as VC, FV, LD, LA. It is revealed by prayer or ritual. This continues over time as prayer and rituals are continued. She has 1 T properties equivalent to those of an icon. It is linked to entities (these are not FIs)

We find a case of the same kind in the miraculous water which comes out of the sarcophagus of Saints Abdon and Sennen in Arles-sur Tech. Before the distribution of the water collected in the sarcophagus, once a year, at the end of July, a procession takes place in the city. This is important but not enough.¹³

¹³ FI for Intelligent Forces or Firthes. These are combination effects of Arkhams and Mahkras.

As before, it takes either prayers or a ritual to reveal this water. Water miracles of Lourdes and Fatima are almost the same.

Chapter XV

1. *LESPAVS*

We have seen that Favæcum has two components, but the experiment described below shows us that it produces a new phenomenon.

Let us put at the exit of the barrel, a piece of wood of circular, cylindrical section, the axis of the cylinder coincides with that of the barrel, such that this piece of wood has on its surface a helix right or left, engraved. We no longer detect, in the extension of the system beyond the cylinder of wood, of avæcum, but there is something else. This is what we will call the "PAV"¹⁴. There will be a right P AV or a left P AV depending on the propeller on the wooden cylinder was right or left.

You can get the pavs using a Vyz shape planted in a plug and the vertical stem put in a bottle. It is good to take a fairly plump bottle. By the 2 oblique stems it comes out for one the right AV P and for the other the left AV P. If you put coarse cooking salt at the bottom of the bottle is even stronger. If we put the system described above in a bundle of avæcum, the Pavs disappear, and there is a pump at Æ.

If we have a beam of P AV D15 and we put perpendicular to this beam a plane mirror at 2 reflecting faces, Pav R becomes Pav L. Similarly, Pav L changes to Pav R.

If we continue the experiment by placing a second mirror cutting the beam parallel to the first, if the mirrorless cannon emitted a Pav D, it still emits a Pav D (same for the Pav L).

If we put an even number of 2-sided mirrors, parallel to each other and perpendicular to the beam and intersecting Pav R or G is kept as Pav R or G. If the number of mirrors is odd, Pav R

¹⁴ This phenomenon has a vague resemblance to the rotatory power of substances like quartz which have a circular birefringence with respect to light.

¹⁵ R or L for right and left respectively.

© EÜRECALL

where G is transformed respectively into Pav G or D. If we send a beam of Pav D or G on a body in rotation this one is preserved but it is amplified.

Some bodies of chemistry watered by a precise wavelength, for example in the infrared, will emit one of the two Pavs. If we prepare this body to be pumps to Æ , a watering by a other wavelength gives the same Pav.

In chemistry, we learn that so-called optically active bodies have special properties. There are those called levogyres or dextrogyres or the half-half mixture of these two genera which is called racemic.

If we place a racemic mixture in front of the avæcum cannon, nothing new occurs, we have always the avæcum. If we put levogyrotory or dextrogyrotory bodies, we obtain Pavs D or G. Life choose the dextrogyre.

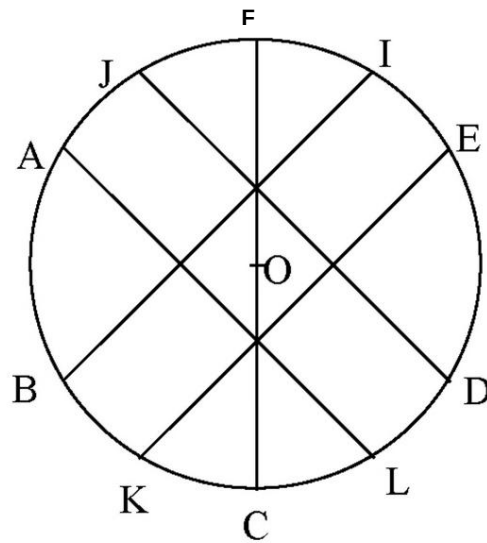

If we put in front of an avæcum cannon a crossed out square, we have the pav that we would obtain by putting in front of this same canon of left tartaric acid. By replacing the left tartaric acid with the right, we get the other pav.

To cross out a square, draw a segment extending beyond the edges of the square and inclined at an angle of -23° with respect to the line NfSf which is an axis of square symmetry. If we draw the symmetric segment relative to the NfSf axis, we obtain an intestable form. This form posed vertically to the output of the barrel, contrary to the barred square does not emit a pav apparently because all the system becomes untestable. If we make the square symmetric to the barred square testable by forms additional for example, we obtain the other pav and the form constituted by the cannon and the square is then testable.

Let's see a shape that emits both tiles simultaneously: Consider a circle with center O.

Divide it into six equal sectors by the points ABCDEF. Let's draw the diameter CF. Let IJKL be the respective midpoints of arcs EF, FA, BC, CD. Let's draw the chords BI, DJ, EK, AL. They are parallel two by two. The figure constituted by the circle, the diameter and the four cords emits the two paves. If we pierce the center of the circle, there are no more cobblestones

© EÜREECALL

This figure is linked to that expressing the dynamism of the FFV. Indeed consider the hexagon non-regular stellate ACEBFD. This is the one that represents the rhythm attached to the FFV. If we draw the interior bisectors of KRF angles, ADF, RFC, RAC, we obtain the four strings indicated previously.

If we put this vertical shape parallel to a flat ice, reflecting side facing the shape, we amplifies the pavs. If we place a second mirror parallel to the first and its axis (we take it rectangular for example) in the axis of the circle, it is even stronger. If we place this form vertical between two copies of the form expressing the rhythm of the FFV, the whole vertical, the planes of the parallel forms, we have a powerful avæcum but more pavs.

CHAPTER XV

Its proportions are very precise. This one could have been constructed starting from the meter as unity. We could have started from another unit, for example, a unit associated at the time or a one not dependent on the moment, but attached to another phenomenon; in these different cases the effects and states will be different. The more one is interested in an adequate unit, the more the properties already found strengthen and others appear. But here we have taken the side c of the basic square and we have sought the length of the side assuming it to be regular. We arrived at 2.26 C. We must place the shapes to energize slightly below mid-height; in this small region we have a channel. It is necessary that the form put inside does not have more than 15 to 18 cm of space in order not to disturb the pyramid.

Naturally, to operate under the desired conditions, the pyramid must be closed.

At the solstices new effects occur due to the "rain" of VC

We can draw from this study that the forms, by their multiplicity, can be used many ways: their proportions, the place, the moment, the unit chosen for the dimensions, even several units can be set up simultaneously, all of this will result in a form which will be operative for the obs.

Naturally, to function correctly this pyramid cannot be placed just anywhere.

II. The FIRTHES¹

Frédéric Dufourg had discovered and used what he called the "Intelligent Forces" [1]. It was besides the partial title of his first manuscript, which, unfortunately, got lost. On the other hand his second manuscript [2] has been edited. This is the application of "intelligent forces" to the study "Brute Forces of Matter of the Three Kingdoms".

We said in [1] that Dufourg insists that "the brute forces of the three kingdoms" do not can be fully assimilated only on condition that the "Intelligent Principle" is associated with them.

During our research we at some point came to the conclusion that we touch this "Intelligent Principle" or, following Dufourg's name, the "Forces intelligent".

We will therefore find forms that will be said to be "linked to the Firthes". Note immediately that a living being is not necessarily linked to the Firthes. Inert forms can be bound to Firthes: for example certain stones; they are found in the countryside, in brush, near places rocky, in paths.

A statue of Easter Island allows you to be in contact with the IFs This allows you to go a lot further than what Jean de La Foÿe had found about these statues who had only looked for the eifs and states. In general the eifs were harmful. If we consider a set of statues, we have access to one or more FIs that can be manipulated simultaneously, which makes it possible to work with much greater subtlety. At the same time we model the IFs, as we can also model them by forms.

We can "channel" IFs through vertical planes. Several plans made by plates of rectangular wooden or metal plates placed vertically on the ground, on the longest side, the plates not being in contact with each other, give access to the FIs. There are multitudes of FIs, their creation will depend on the setup. You can associate angles and crystals: this will allow you to have firthe-related forms. This is the case of dihedral angles or solid angles. When removing the crystal, it is not related to the firthes; for it to be, we can introduce a form additional.

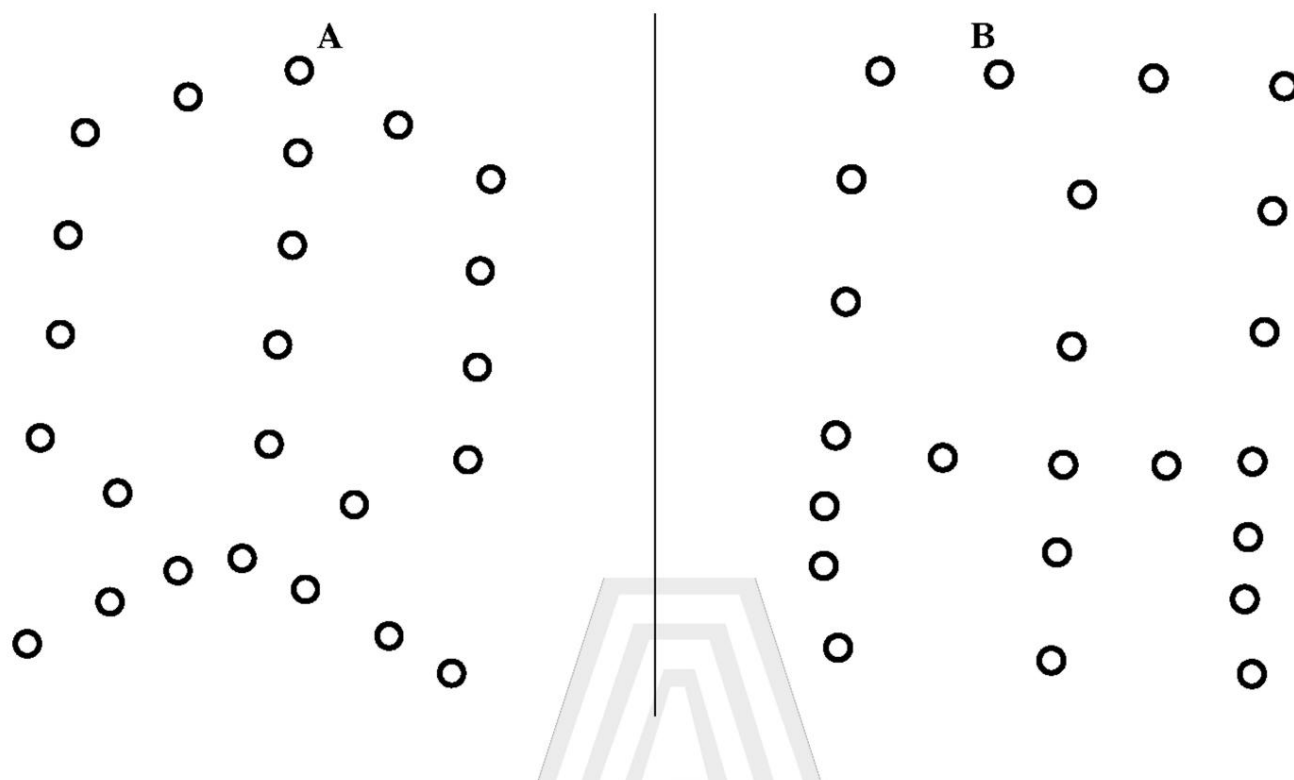

In the case of plane angles, we do not take crystals but autioth. The manipulations are delicate; they can generate other phenomena which are not apparent at first glance.

¹ Abbreviation for Firthe: FI. This word is feminine.

III. *Components of the acaecum*

It has been previously reported that avecum has two components: avecum can be separated into its components.

For this we put at the exit of the avæcum cannon a vertical plate pierced with holes according to the shapes cut out by A and B.

If we put form A in front of the barrel, the avæcum gradually disappears, even between the barrel and the plane. of the shape: the sinusoidal component appears.

If we place the 2 shapes on the beam, their plane always perpendicular to the axis of the beam, whatever their position in relation to the barrel, nothing is detected.

Note about the avæcum that some gray-lead skies emit avæcum. If in a room we place a table with the color of the previous sky as a background and in the foreground the very green trees the painting emits avæcum. The avæcum is detected in a volume a little superior to that of a prism having as its base the flat surface of the painting and as edges the perpendicular to the edges of this surface.

© EÜREECALL

A dodecahedron whose faces are pierced with fairly large holes, placed between the oscillators of G. Lakhovsky's multi-wavelength oscillator emits avecum during operation of the device.

IV. Forms related to VAether

There is a very particular type of forms which, when tested, appear to be "related to the $\mathcal{A}E$ ", that is, there is an immediate connection between the $\mathcal{A}E$ and themselves. We do not know the nature of this link, we simply know that the form linked to the $\mathcal{A}E$ has properties that are quite astonishing to generate the avæcum, LC and LD or eifs.

There is a precious stone which is linked to the $\mathcal{A}E$ (one is a reservoir of $\mathcal{A}E$, or a pump of $\mathcal{A}E$), it is Jasper.

We will see several examples of $\mathcal{A}E$ pumps; they also have a great interest because often they make it possible to create avæcum or LC and LD, or the eifs with high C. de T., and their flight or again FV and VC.

If you put a stone that has a psychic field (CP) near a form that is a reservoir of avæcum, the CP is singularly amplified. (CP for related to the Firthes)

We have previously reported the following assembly: 4 avæcum cannons, identical, each placed at a vertex of a square and facing each other two by two along the diagonals of this square. If we test, we finds that these forms constituted by the four guns arranged according to the description are a reservoir at $\mathcal{A}E$.

If the guns above are large, this can be very important. If we dip a tuning fork in the air liquid, it becomes an $\mathcal{A}E$ pump.

By heating water in a glass container, itself surrounded by earth which is contained in an earthen pot, the earth becomes an $\mathcal{A}E$ pump; if we put plants in this soil, after cooling, they emit VC and C. de T.. If we take this water, we put honey inside and we heat it again, then the honey becomes a reservoir of $\mathcal{A}E$. It is interesting to consume this honey.

An $\mathcal{A}\mathcal{E}$ pump can be obtained from certain alloys of tin which are melted in the sun;² then coarse salt is sprayed onto the molten alloy; on cooling we have a solid mass which has an ext. By adding salts of certain light metals, the whole can emit avæcum.

Some vertical walls built with parallelepipedic stones can, under conditions very precise, becoming pumps to $\mathcal{A}\mathcal{E}$. Not all stones have to be parallelepipeds too perfect. We would have the same with an imperfect checkerboard with black and white squares. Naturally we talk about an imperfect checkerboard but it should not be done just anyhow. Yes, on this checkerboard imperfectly made, we put stones in certain places, we can amplify the pump character to $\mathcal{A}\mathcal{E}$. We can also make a regular and hollow convex dodecahedron, put cubes in it solids quite small compared to the dodecahedron and arranged much like the stones above in the wall, then the dodecahedron becomes a very strong $\mathcal{A}\mathcal{E}$ pump.

One can wonder if the blood, in the veins, is linked to the $\mathcal{A}\mathcal{E}$; before going any further, it is about know well what is called blood: we will not take into account the red liquid that flows from a incision made on the skin.

This liquid moreover has an ext, it is that of the individual from which it comes; if this individual has no ext neither does the liquid.

The blood in the veins (we don't know what it is) is linked to the $\mathcal{A}\mathcal{E}$.

The whole blood network, as a form: vessels, arteries, veins, is also linked to the $\mathcal{A}\mathcal{E}$, but the human being is not related to the. Suppose that this network can be separated from the individual to whom it belongs belongs, and that we put it in a dodecahedron (here it is a simple mental experiment!) regular, convex, hollow, something new is happening: the human being linked to the blood network becomes a pump at $\mathcal{A}\mathcal{E}$. The dodecahedron is for the human being a kind of revealer. It's not that it allows the human being to become a pump of $\mathcal{A}\mathcal{E}$ is that it reveals that it is a pump of $\mathcal{A}\mathcal{E}$.

If, instead of starting from the blood system, we consider the nervous system and think about it. put in a dodecahedron, we detect that the human being is a reservoir of another aether, than that, let's say fundamental, Boutard's little serpents. In the last two volumes of the work of V.Rosgnilk, we had hypothesized a multitude of aether s. It seems as well as being human is a reservoir of two or more aether s.

² The position of the sun in the sky must be taken into account. These alloys are found in the so-called "tin" caps closing wine bottles. These capsules are increasingly being replaced by plastic or aluminum.

© EUREECALL

It will not be only the dodecahedron which will be a revealer. Other forms are too. Shapes "revealers" are very useful, because they make it possible to consider properties of forms which have hidden properties. If we do not know these properties, we can hardly use them.

The dodecahedron considered previously is not a revealer for any human being. If we consider for example a human being who is born without an ext, or who has a low FFV, this human being is not a reservoir of $\mathcal{A}\mathcal{E}$. This does not mean that another form will exist and will be revealing for him. The "revealer" cannot reveal what is not (in the sense of existence without reference points).

The human being, from the moment he knows that he is an $\mathcal{A}\mathcal{E}$ pump can emit the eifs he wants, where he wants, in a place desired by him; but also all that we have seen previously and which do not are not eifs. It is the first time, in this study, that we come across forms "revealers". The artifices reported by La Foÿe to detect the vital field of plants or the spectrum of a burning candle are "revealing" shapes. Here the manipulation technique is more elaborate because it is necessary to consider an abstract form: the blood system for example but in the body, as we do not know it seen from the outside, and plunge it in thought into a dodecahedron regular, convex, hollow. Instead of such a dodecahedron, we could have taken a dodecahedron called "pearl"; it would have worked just the same. A study of this type of shape was made by J. of Saint-Venant at the beginning of the century [2] We present in the appendix a summary of the study of Saint From.

Chlorophyll with a developer will give the VC. Hemoglobin with a developer will give the VF. For one as for the other, it suffices to take as revealer a dodecahedron or a beaded dodecahedron, so to put them inside separately. If we put them together we will have both VC and FV.

We thus realize that the chlorophyll by this developer, is linked to magenta and that hemoglobin is bound to FV. The developer seems to detect a reversal made by the human being.

There are other "form revealers" than the regular, convex or beaded dodecahedrons. By example a language like 1, Hebrew is a revealer of forms; for this you have to take Biblical Hebrew. Similarly, Hebrew letters associated with constellations favor the transfer with shapes. The Grail, the Tables of the Companions are revealers.

Ambergris is an $\mathcal{A}\mathcal{E}$ pump. If we place ambergris in the center of a closed dodecahedron, we detects avæcum as well as VC, FV, LD and it's still an $\mathcal{A}\mathcal{E}$ pump. Consider the 5 Platonic solids. Let us name the P_i where i is the number of faces:

© EÜRECALL

tetrahedron: P4

cube : P6

octahedron: P8

dodecahedron: P12

icosaèdre: P 20

Let's make a montage: $P_{12} \rightarrow P_{20} \rightarrow P_8 \rightarrow P_6 \rightarrow P_4$. If we place a brass wire such that they cross all, this thread becomes an $\mathcal{A}E$ pump regardless of its length.

Léon Sprink made a study on F iconography.

Forms, which can be revealed by a dodecahedron are the icons, but one can work on an assemblage of circles through which the icon is placed. Sprink was very insistent in his research on the traditional layouts used to establish the plans of the monuments religious and he noted that strictly identical lines had been used for the prescription iconographic representations [3]. He insists a lot on the fact that in the West or the East, the arrangement of the circles on the surfaces which will serve as a support for the frescoes, mosaics, and iconographic paintings is strictly the same as that of the surface of a plan of a church.

According to Sprink, in the West, there are very few documents that explain the meaning of the lines. churches and cathedrals. Most of them date from the Renaissance and are questionable for their validity. This is not the case with iconographic representations.

The Second Council of Nicaea was devoted almost entirely to the discussed question of worship images. His decrees shed vivid light on the purpose and significance of Christian iconography. This makes it possible to justify the complete identity of the layout of the plans of the churches with that of the icons. In religions other than Christianity, the worship of two- or three dimensions is prohibited. The approach to the divine is very delicate: we must not forget that the realization of the figure is in the path of the one who will use this figure to contact the divine.

Sprink says: when we find ourselves in front of an icon "what dominates there is the impression of us find in front of a "mystery", evoked and signified". Of course it is useless to look for a even two-dimensional AND structure in an icon. Sprink has this lovely expression: "It's not yet not immobility in the ordinary sense of this term, but the immutability of "eternity

© EÜREECALL

created". Sprink thinks that if the icons are in a plane, it is because, in our natural condition, such is the minimum still allowing an intelligible figuration.

It's not sure at all!

This is true, but there is much more!

It seems, when working with forms, that the planes are often more important than the three-dimensional forms provided that the planes are what we call "inhabited". Sprinkle writes: "If on the icons... the arms, the whole body appear to us as atrophied, it is not in no way a sign of unleashing, but the absence of possible and corruptible flesh", thus linked to the sensible world, and like a presentiment of the glorious body with all its qualities (subtlety, transparency, etc.) which place it outside the phenomenal order" and he points out that we would be a big mistake in equating icons with abstract art. This body is close to the spiritual body of which Saint Paul speaks. The icon could be compared to an attempt to open up an experience mystical. It allows relocation. If he who prays before the icon, moreover the prayer reveals it, puts his thoughts, these can be placed in the revelation which contains a leak, and be placed in the leak where there will be a location that will give animated images, but additionally containing eifs, states, atmospheres linked to the divine which further amplify the effect of localization in flight and stabilize him but take nothing away from his life.

Sprink talks about the impression of life given by the beings depicted in the icons. This is already the beginning of the process of leaking and filling the leak.

As early as 787 the Fathers of the second Council of Nicaea expressed themselves thus on the subject of the traces of the painters icons: "The composition of religious images is not left to the initiative of the artists; she comes under the principles laid down by the Catholic Church and religious tradition".

And again: "Art belongs to painters, the order and arrangement (of works of art) belong to the Fathers".

Sprink talks about the colors with which the icons shine; he says that to find similar ones he would have to be in the steppes and deserts or high mountains before the day illuminates the sky. But he says that icon painters have gone even further thanks to the "assist", these tenuous rays of gold which weave a transparent veil and, as a result, attenuate the contrasts of the colors of the refracted light. They signify the light like that of Mount Tabor which, moreover, the painters icons have only ever been able to "signify" since it is outside our means of expression and of representation. It is always about location in leaks where color varieties, or maybe even the concept of color imposes itself, breaks up the global and flows a little into the

© EÜREECALL

decalaire to fill, fill the leak. "In the West, we represent the saints as they were among us, in the East, they are represented in the "ævum" or "created eternity", such as they were assumed, transfigured and "realized" in the brilliance of taboric light" writes L. Sprink.

Christ has been represented on an icon. This resulted in the Virgin and Saints being able to be represented. All the theology of icons is contained in this lapidary text which claims to be from Saint Paul "The Son is the image ("sixoov") of the invisible God".

Most Russian theologians recognize the sanctity of icons and the liturgical function which they exert thanks to their form.

By adopting this point of view, the Church of the East recognized in the ritual icon the sign of a supernatural presence; its liturgical meaning is based on a resemblance to an archetype living in another world than our phenomenal world. It must be understood that with these concepts, the man locates.

Sprink writes: "Invited to choose from a rich album an image of the Virgin which reminded her of the her "Belle Dame", Bernadette put her finger, without a shadow of hesitation, on an icon of the 11th century, preserved in Cambrai. Neither the virgins of Raphael, nor that of Murillo or Vélasquez have found favor in his eyes" and L. Sprink continues: "Because, in the end, that is a icon: materialization of prayer and flower of contemplation". The so-called "symbolic" Virgins shed striking light on the major guidelines of Christian iconography. By example, the "Praying Virgin", standing with her hands raised, as Sprink described her, symbolizes the Church. She is often depicted in the apses of old churches in Russia (the oldest date 1035; it is in Kyiv).

Saint John Damascene said: "Do not represent the divinity, do not disguise it as blind people whom you are, because it is impenetrable to your eyes. By figuring the camel envelope, I bow full of faith and I glorify the Virgin who gave birth to the Lord". (You should know that this text is not found in the writings of this saint, but that the content is consistent with his teaching).

Marian iconography becomes a replica of the holy liturgy which never tires of signifying in the same texts, mysteriously interchangeable, as Sprink points out, earlier the

Mother Church, sometimes the Mother of Christ who never ceases to give birth to her Mystical Body for Life

everlasting. Taken under this aspect, the icon of the Virgin-Church appears to us as a triumph of pure interiority.

We see that the concepts Church, Mother Church, etc. are not attached to the rational C. of C. It's necessary to understand them, use developments of the kind presented in the study, inserted dans[1], on the World of Silence by Max Picard.

It should not be forgotten that adoration is strictly reserved for icons of the Saviour; those of the Blessed Virgin and Saints are only venerated.

Sprink places great emphasis on icons so that the minds of the faithful of the Christian East can grasp their meaning. He sees a certain equivalence between the writings of the great mystics of the West (011 think in particular of the Rhenish mystics and the Flemish mystics) and the icons of the Orient; on the other hand in the East the texts are rare.

You have to have been in the contemplation of an icon to grasp its secret meaning which puts, from the outset, at the extreme limit of the usual room. An RBB cannot address these states and this domain. Let us quote with Sprink the curious phenomenon called in Russia "prosvietlenie". It is common in Russia since the great revolution of 1917. It has been attested by countless witnesses. Icons, very old, blackened by the smoke of candles and night lights that had been burning in front of them for centuries, with a varnish ruined by time, suddenly recovered, overnight, all the freshness of their colors and their primitive brilliance.

Similarly, some domes, tarnished by age and lack of maintenance, suddenly "illuminated" and shone as if they were golden yesterday. This mysterious phenomenon concerns above all the icons of the Blessed Virgin. Obviously, adds Sprink, one could not expect, in the current circumstances, a full investigation or technical verifications, but the testimonies on this point are so numerous and concordant, spread over such a long period, that it would be very difficult not to take it into account. From the 1917 revolution, a new atmosphere began to well up and there was an impregnation on the icons of this atmosphere. Those of the Virgin were perhaps in their construction more apt to react? [3].

3 It is quite significant that the iconoclasts who fought to the limit against all representations of Christ, of his Mother and of his Saints, nevertheless admitted a holy icon, a sign and image of the presence of the Lord, the Eucharist.

EUREECALL

**“They knew almost everything; nothing seemed to belong to them
difficult, neither to carve the nephrite, nor to melt for, and all that, arts
and sciences, proceeded from Quetzalcoatl”**

Brother Bemardino of Sahagun

This is from a chronicle of a cleric who was with the conquistadors during the destruction of civilizations
Indians of the Americas.

The Spaniards were chosen to accomplish enormous destruction in order to gradually put in place a system which now reveals
itself to us as the meaning of a gigantic puzzle. [Recall this thought of Cortez on the destruction of Tenochtitlan: "It was sad to be
the instrument of its destruction but it was part of our plans and we had no choice". It is obvious that a historian will not understand
this remark in the sense in which we take it. It is too steeped in rationalist propaganda!]

It should not be forgotten that the machinations are not disclosed in the Histories of the Peoples, so all knowledge is distorted.

This remark by Brother Bemardino of Sahagun perfectly illustrates the incomprehension of the rational thought in which he was
immersed - with respect to another thought - attached to the other Field of Coherence the Indians, by what is called the gods and
say their mental constructions which were in a R. de C. of the Other Field of Coherence knew how to use these entities, because
they existed in this R. de C. - D' elsewhere perhaps there were several R. de C. one for each civilisation: Olmec, Maya, Toltec,
Zapotec, Incas.

Moreover, some R. de C. may have been very close as in a R. de C. beam due to their similar polarors (it is recommended to refer
to [1] where the Theory of C. de C. is presented). C. from a model where wandering points are used to set up the R. of C. and the
swarms of coherence) which makes civilizations seem to follow each other while they mix by similarity of R. de C. Their differences
would be the expression of the structural differences of R. de C. .

The god and the gods become the very structure of R. de C.; it is enough for humans to traverse this R. de C., at the same time
they construct it. "They are what they are" one could say. They are in becoming, which is the expression of "being being", that is to
say, the Idathema.

For an outside observer, who is not the adequate thought, "they ask and it is given to them," so he sees and then does not
understand that it is a question of the structure of R. de C.

The conquest by the Spaniards, this Indian genocide, were the fact of bringing together a bundle of usual R. de C., thus there was
destruction by assimilation by rational thought, and this with a goal - since the goal exists being given that we are talking about
habitual thought - which becomes more localized every day.

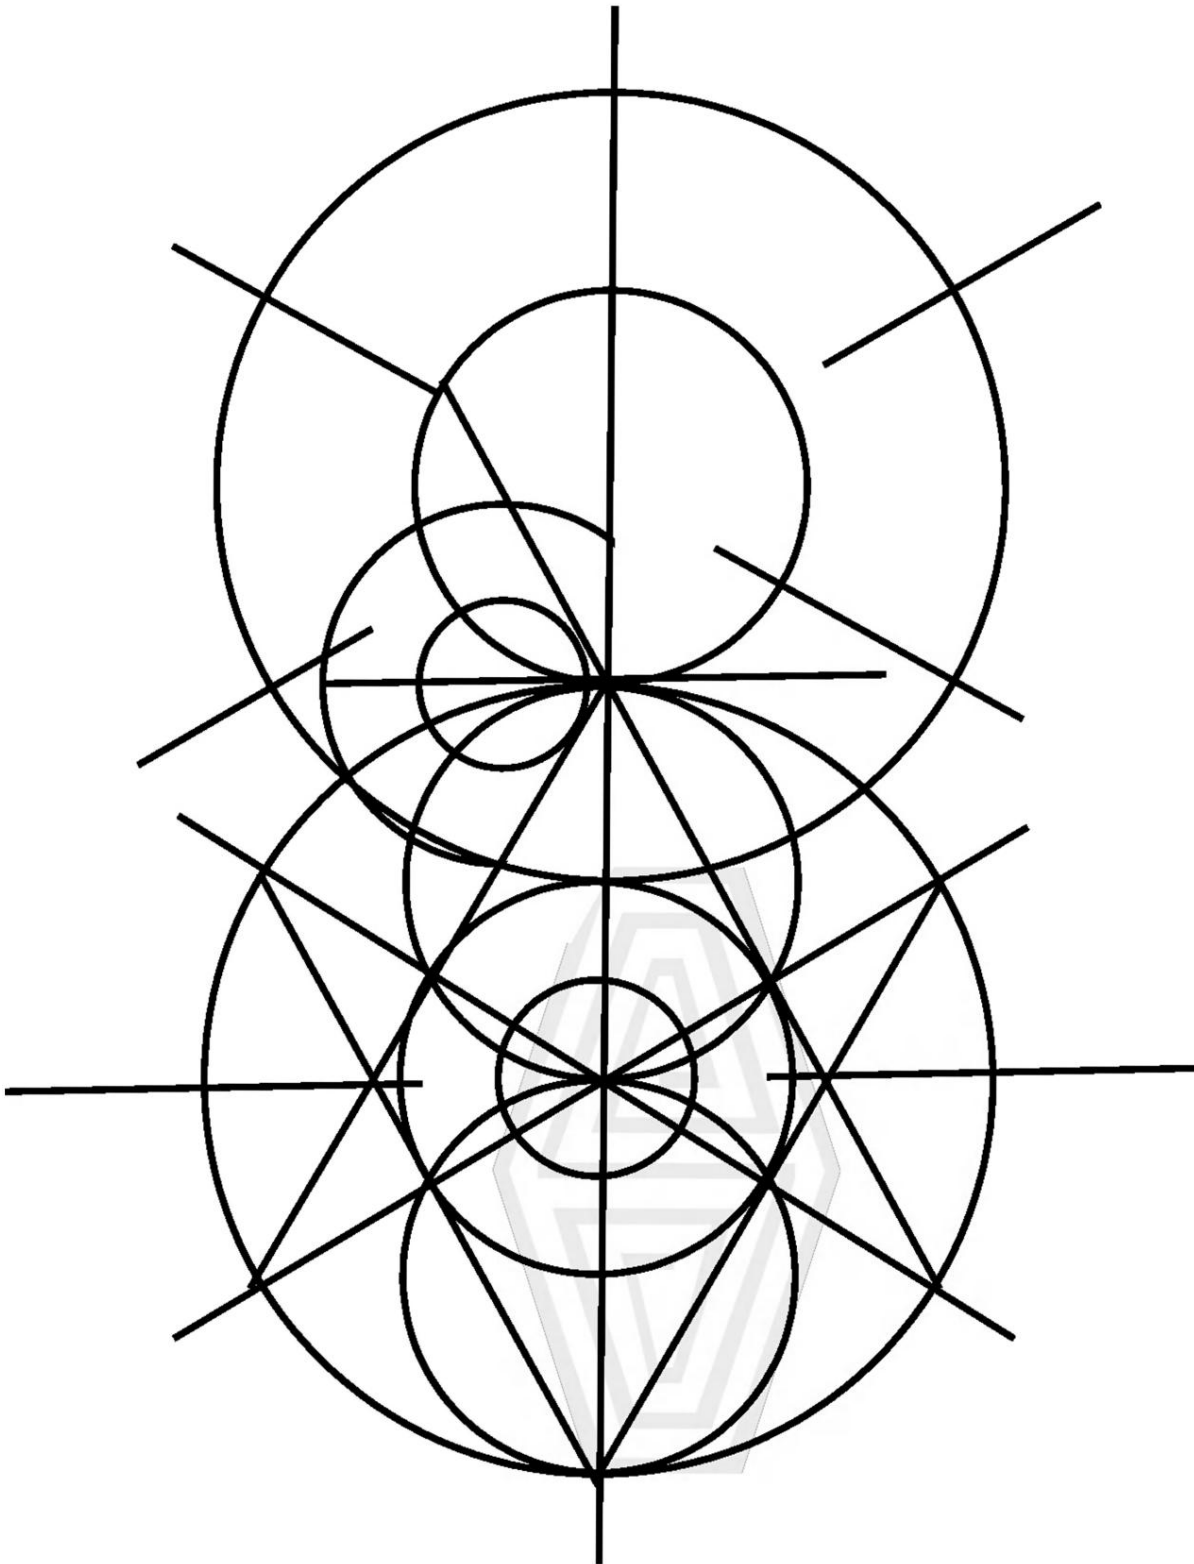

Outline of the icon of Our Lady of Vladimir

(It was chosen by the Church as a sign of unity on the eve of the Council)

Layout at the request of L. Sprink de J. Grivot, architect DPLG

© EUREFCALL

Let's draw the circles. By adding the rhythm form attached to the FFV, we have a transfer with the icon, moreover one detects of Favæcum if the plan is put vertically. It is an Æ pump.

If we rotate a gyroscope in a dodecahedron, the whole becomes an Æ pump and emits Favaecum. Gyroscopes are very important; they have been used in devices that can

© EÜRECALL

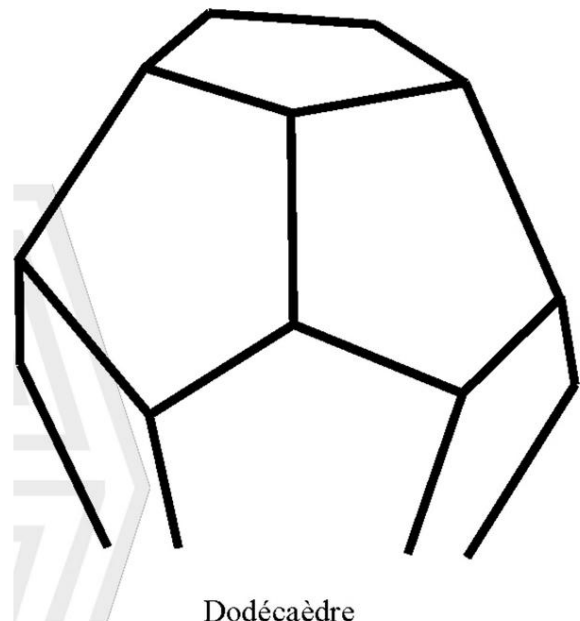

overcome gravity. The RBBs persisted in claiming that these devices did not work. not. And yet they worked! It is necessary to associate several gyroscopes. It's good to have three. It is then observed that the device becomes a à pump. This is not enough to avoid it, but we do realizes that we are not facing a technical object (OT), but a phenist object (OP). As pointed out in [1], the conservation laws of rational mechanics do not apply not to such systems. One such device is Eric Laithwaite's machine: it has only two gyroscopes which are driven by a motor and can move on a helical upward rail. Let's go back to the regular convex and even beaded dodecahedra. We realize that a constellation as the Little Dipper is linked to the dodecahedrons. Let's do the following setup:

cardboard pierced with holes reproducing the
constellation, as it happens
the little Bear

and

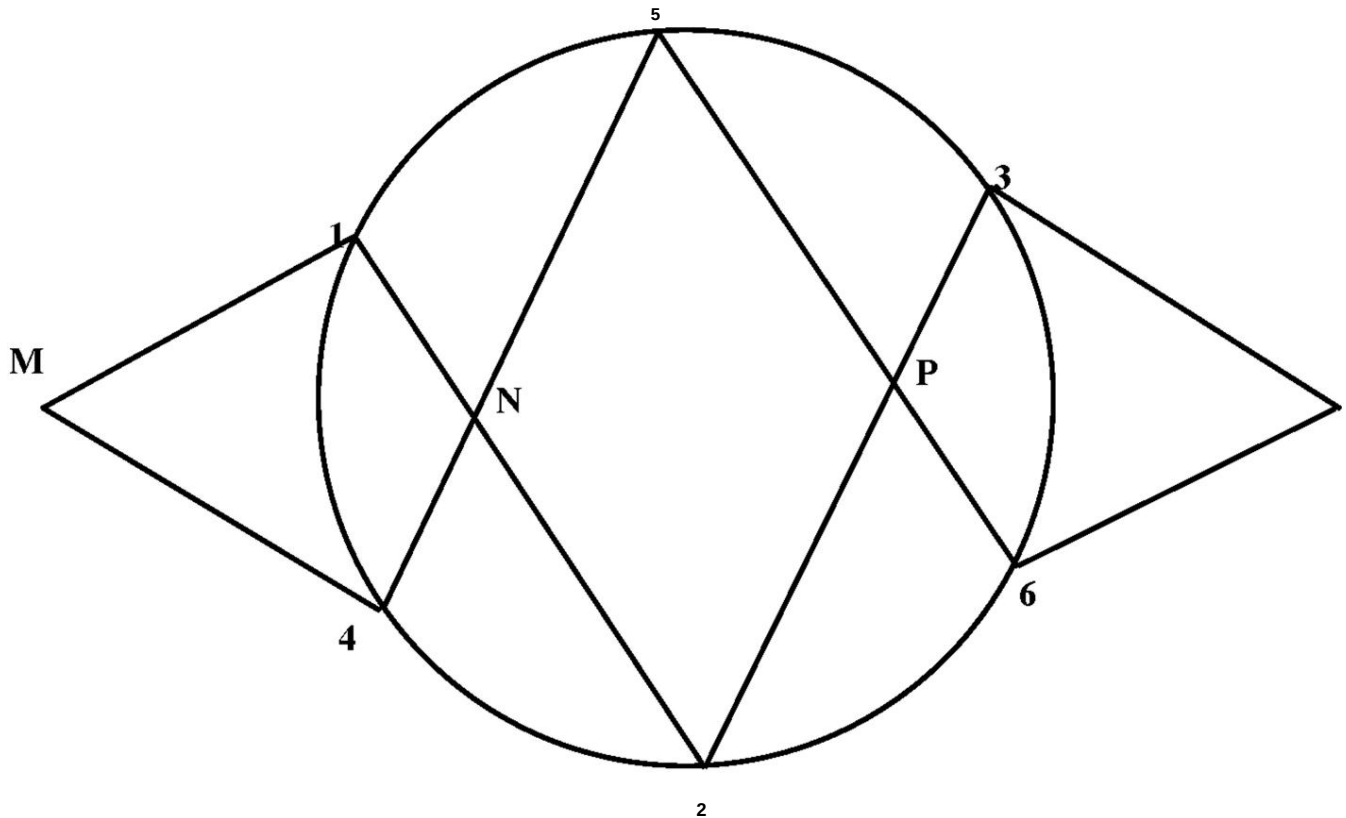

i

light bulb on

The dodecahedron becomes a à pump but does not emit avecum. If you look at the Little Bear at through a beaded dodecahedron there is an effect on the beholder. Of course it is very subtle. From the rhythm shape related to the FFV, we can derive two planar shapes. Both forms have very interesting properties. First they are linked to the Æ, they have an ext and an int. They send out avæcum very strongly, whether they consist of a single wire or plates.

© EÜRECALL

(We have reported the figures that we had put on the rhythm form of the FFV)4.

The plates are: M1N4, N5P2, P3Q6 - or the trace with a wire: M123Q654M.

If we put the plane of this shape vertically and parallel to the lines of faces of a field magnetic, the characters indicated above are amplified. On the other hand, if we want the same property of amplification with an electromagnetic field it is necessary to place the vertical plane of the form perpendicular to the field propagation vector.

If we place this form parallel to a mirror, it is even stronger and we associate the form with curved surfaces. The same is true for the other form. These two forms can be placed in perpendicular planes. All characters are reinforced, except that the associated surfaces are replaced by a volume. We further amplify if the line of intersection of the 2 planes which is an axis of symmetry for the previous shape, is vertical. In these last two cases, we can place these

4 In this case arcs 1.4, 4.2, etc. are considered equal. Other FFV patterns where they are not equal, exhibit the rhythmic form associated with the more operative FFV. One can thus generate, without coloring, the rhythmic forms which resemble the seal of Solomon - VC, FV, LD, LA, LC, LB.

two forms in a magnetic field; this must be parallel to the earth's magnetic field so that Pavæcum is always detected.

But each of these shapes can be replaced by suitably arranged angles. These corners can be flat or dihedral. If they are flat, they are inserted into a rectangle, if they are dihedral, they must be in a parallelepipedal box.

The two forms could not be placed on top of each other without losing the avæcum. With the angles, the tackle is possible, the avæcum is even stronger. We can even, if we stay in the plan, avoid drawing the rectangle completely. In space, we can also eliminate the box and only use dihedral angles⁵.

As we pointed out in [1], angles have amazing properties. In some cases on the study of shapes, we replace them with systems of angles. We can also have in the case of the plane, angles with a rounded point, the same for dihedral angles and solid angles when we are in space ³³.

A full 16° apex angle cone emits avæcum and is an Æ pump. It is the same for a full cone with an apex angle of 74° .

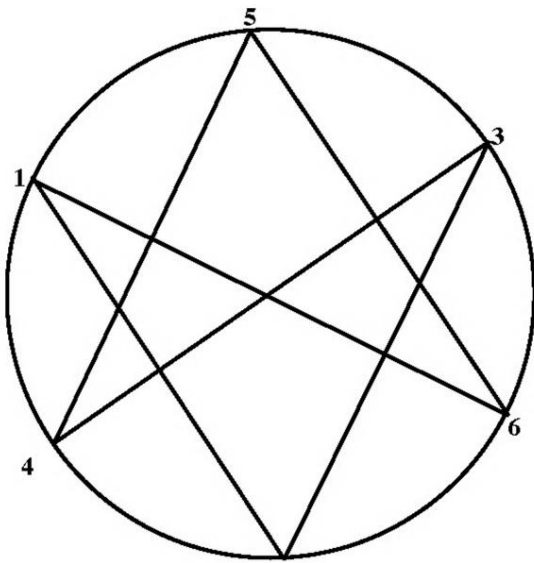

One can ask the question, as for the lengths, to know if there is an angle which can be imposed as a unit and which is related to an angle unit. For the distances, we know that there have been multiple cubits according to the times, so we had gaping shapes at the time and transported, they could enlarge the moment. The meter is not a limit that allows operations of previous units. All these old units were not operational; there is none had that some. On the other hand, some of these units cannot be compared with each other and particular to the meter without deleting the operativities of the forms which are constructed using these units. So if we want a shape, for example a parallelepiped, to have such a property, we can find a unit which will make it possible to locate this shape and above all it will have the property sought. Yes we copy this form by measuring with a meter for example or one of its sub-multiples, the newly constructed, apparently similar shape will not have the desired property at all. It will be much more localized than the first.

⁵ One can place for example these shapes and these arrangements of angles in the energizing pyramid mentioned in a previous chapter. It takes on amazing properties. In particular, this pyramid is associated with curved surfaces in the case of the first two forms and a volume if they are used together as we have indicated.

But we can find a unit of length linked to the meter which makes it possible to compensate for these units attached to a form. In the same way one can find a unit of angle, these two units are moreover related.

The angle unit is related to the degree; it is: $2^\circ 3'$. Can be used with usual protractor for measure the angles but we will bring them back to this unit to find the desired angle with the pendulum. Here the case of the solid angle is not solved because there is the number $7C$.

We can take the form of the rhythm linked to the FFV with angles. The latter will issue many avæcum. It responds to FFV6 7. You have to mark all the angles and keep their locations in the figure obtained by the first plot.

"AT

\ x x

6 It has no ext while the FFV has one. If it is made with dihedral angles, it has an ext. Note that the dihedral angles have the same value as the angles drawn in the plane. These angles can also be embedded in a closed cylindrical box, their edges must coincide with the generatrices of the cylinder.

7 Let's use the Hebrew again: the H is linked to the $\text{\AA}$; YH is a reservoir of $\text{\AA}$ but not HY. YH is an abbreviation of "Etemel". Note that the wormwood plant is linked to this YH. It is linked to the $\text{\AA}$ also. This is linked to the sides YH and place one H in different places on YW another H, we get YHWH. HW Y WH and even a

This allows a collapse in YH. Note that:

- hA Sh • fire
- YH abbreviation of “Etemel”
- hAYSh the Man actualization of fire
- hAShH the Woman, the living fire

then Y,H in equimsey gives hA. A shin arrives; it separates the equimsey; we have: hAY and hAH then it is formed hAY-Sh and after hAYH . Then hAY-Sh becomes the hAYSh.

This confirms the importance of angles. Moreover Francis Warrain in [4] writes about the geometry: "The neutral element is the Angle, because it is the angle which allows the diversity of the rays and the determination of curvatures. Finally the Angle is the source of all spatial metrics. Indeed, it is as a chord of a circle that a segment can constitute a standard of magnitude because of the fraction of a circle associated with it. This fraction is undoubtedly arbitrary since it depends on the chosen radius, but this choice made, the segment is qualified by a structural relation between the part and all. On the contrary, one line segment compared to the other will only give ratios similarity without fixing any unity inherent in the geometric structure".

Should we deduce from this that homothetic or more generally similar figures have the same properties for what interests us? When it comes to similarity, that won't always be true because there are relations which can cause a form to take on new properties in its neighborhood after a rotation. As far as homotheties are concerned, it should not be forgotten that the obs is subject in its tests to its tacit knowledge and in it is the volume of space selected. The properties are not the same according to this volume of space.

So it seems that distances should also be brought into play. On the other hand, if we assume that the two dimensions are as fundamental as three, we can describe in a plane a network in which is placed the obs and the identification of a form by this obs is not a point but a finite set of points on this network. The distance from the obs to this shape is then an angle or a system of angles. This is necessary if we want to account for the mental displacement of the obs in his C. de C. as well that of the existence in this same C. de C. of other obs which are only put in place by its care.

Three-dimensional space emerges from these planes. Plans also come into play when the precise observation of the twenty-two Hebrew letters (Biblical Hebrew). To this set of twenty two authioth corresponds a set of twenty-two planes. Note that at an ant ne does not correspond to a precise plan.

Simply these two sets have the same cardinality. We can have the traces of these twenty-two planes on a horizontal plane (none of these planes is parallel to a horizontal plane). These twenty two planes have an ext (the set) and the FFV is associated with them. They are also associated with a volume form. They are not linked to the IFs but we can easily arrange for them to be in contact with a wide variety of FIs. If we put the traces reproduced on a paper in a cathedral, this set behaves like the set of planes. If we put them in the pyramid

energizing considered above, a very powerful avæcum is detected but there is no FFV ni it is not an Æ pump.

There is a flat layout of 28 points which creates a very strong avæcum; this has an ext and is a pump at Æ8. Let's replace these 28 points by two representations of projective geometries each on a flat surface (we will pay attention that in the representations of projective geometry, the straight lines are arbitrary lines); the two surfaces being in the same plane but separated through a hallway. For one geometry, $k = 2$ and for the other $k = 4$, so that the total of their points or lines is 28. These two representations being arranged as we have just said, we finds, if one sends avæcum in the corridor, the two components of this avæcum; if both geometries are in the same plane, but without common point, one detects a very powerful avæcum, it's an Æ pump and it has an ext.

Let's go back to the 28-point planar layout; we can further amplify the avæcum and the character Æ pump by placing a copper winding above the board where these 28 stitches are made through holes, or from below.

If we pass the wire through the holes, crossing the board, we destroy any avæcum and the assembly is no longer linked to the Æ. The current, if a current is passed through the winding, transport of the avæcum. But we can link this plane figure with 28 points to a rhombus either in volume, or a flat figure representing a section by a plane of symmetry of this rhombus. We also have considerable amplifications of all that has been pointed out previously.

Let us say a few words about these two-dimensional rhombs : they were described by Jean Servier in [5] Servier presents it as a strip of wood or metal placed at the end of a cord or of a strap that a man twists at arm's length. The man turns at the same time on the object. There is a whirring sound as it rotates. The Dogons, the Aruntas (Africa), the Bombaras (Africa) say that the rhombus was transmitted to them by geniuses or was carved out of wood of acacia, sacred tree, recognized as such by the initiates. In Africa the rhombus is often linked to initiations of men. Similarly, the rhombus figures as an initiatory instrument in the islands of Torre Strait s in Melanesia and the Solomon Islands.

In Malaysia, it is used by shepherds to ward off wild animals.

8 The 28 points are linked to a deeper notion, which is that of the Æ crystal. On the other hand FÆ is stronger if one places oneself in a plane parallel to the rays of the sun.

© EÜRECALL

In Ceylon, it is associated with certain Buddhist ceremonies.

Often, and in very different places, he seems to have a formidable power over women.

In America it is known to Eskimos, Apache Indians, Navahas, Koskinas, Kwakiutls (British Columbia), California Indians, Pueblos (New Mexico), Hopi and of the Zuni. It is used in the latter to invoke clouds, thunder, rain.

It is still found in central Brazil where it is used to keep women away from the mysteries accomplished by men.

This instrument is found in Scotland, in Cantyre, in the County of Argyll where it is associated with an ancient celestial god. In the County of Aberdeen cowherds used it in the past (even again in 1885) to protect their herds from lightning; Servier does not give any recipe. We find the rhomb in the Basque Country: it comes in the form of a wooden board, a little serrated, whose shape is no longer that of the flat rhombus of which we have spoken until now. He is attached to a rope and the shepherd twirls it around so that the roar drives the mares of the herds, these beasts being able to frighten the sheep at night. It is used in Béarn also to ward off mares seeking to enter sheep pens.

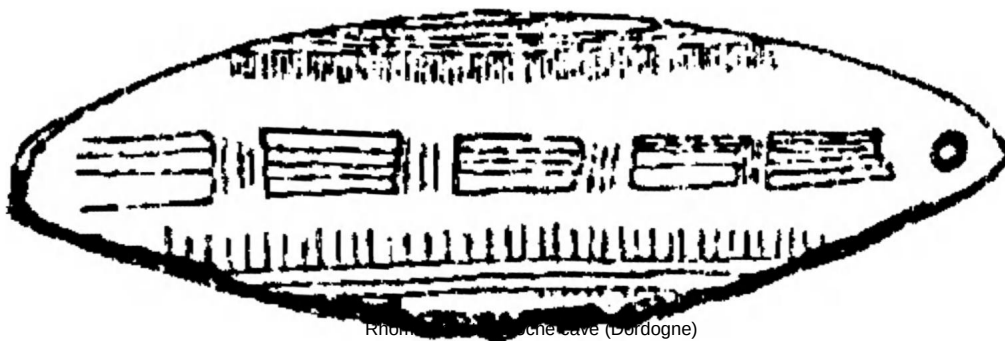

It is also found in Sicily and Portugal. In this country the elders forbid children to do resound their rhombs at harvest time.

People in prehistoric times had rhombs: one was discovered in the layer Magdalenian rock cave in the Dordogne. Some have even been covered with ochre. They bear incisions corresponding to partial representations of manipulations of the $\mathbb{A}$. In Greece, the rhombus was present in the mysteries of Bacchus, Cotytto and the Mother of the gods. He has some been discovered in gold, bronze and even carved in rare stones.

Pliny reports that in his time, in Italy, it was forbidden for women to walk on the paths by twirling their spindles as it was believed that this could jeopardize the success crops.

If we swirl a flat or volume rhomb, we detect a powerful $\text{av}\mathbb{A}$ but it is necessary that the rotational movement in the counterclockwise direction. If we make the movement in the direction of Clockwise, we have no $\text{av}\mathbb{A}$ at all; a state is created $\mathbb{K}$ Sh Ph with reversed Sh>

It is indeed necessary to avoid that this state is placed on the harvests but is this the only reason prohibited?

One can notice serpentiform designs on these rhombs. Are they a reminder of the little ones snakes of Louis Boutard [1] or the orange component of the avæcum? Is there a connection between these serpentiform signs whether they are the components of the Æ or the avæcum? We don't know not !

APPENDIX I: The "pearlized" dodecahedra.

These curious and strange objects greatly intrigued their discoverers.

It was in Germany that the first somewhat general study on the subject appeared in 1892. the professor Couze¹⁰ enumerates in this study all the openwork dodecahedrons that he was able to this date. It happens to fourteen different. It gives for a large number of them the dimensions exteriors and openings for the faces. He tries to find probable uses for it.

¹⁰ Director of the Archaeological Institute of Berlin.

All are foreign to France [2]. He mentions in postscript a specimen found in Hungary.

In 1894, Professor Erman from Lausanne, presented in [2] an article about one of these objects found in Avenches. Twenty-four specimens appear in tables but without other details than opening sizes.

He also very judiciously discusses the various hypotheses put forward for their destination. He cites a new directory of these objects for Germany, plus eight new dodecahedra reported for the France by Heron de Villefosse. In France these objects are in public collections or private: Louvre, Lyon, Poitiers, Rouen, Vienne, Troyes museums and company collections London antique dealers, Courtot, Bayer, Jouandot, Ponroy, Bertrand, Mélines¹¹.

Saint-Venant describes or points out forty-one dodecahedra. Line thirties are whole or have no experienced only minor accidents: torn balls or damaged faces, but one can imagine their full original shape easily.

Twenty-eight specimens have a known origin, but as Saint-Venant points out, it is not hardly specified with really useful details except for 9 of them (openly Roman environments: former camps or various ruins). In 3 cases out of these 9, we can quote with precision in the 4th century of our era the probable date of their burial. 13 are of unknown provenance, and 2 have faded away. A serious study on one of them is given by Saint-Venant at the beginning of his work. He it is, at the beginning of the year 1906, the discovery made by Messrs. Mache court, father and son, who ripped up a yard to turn it into a garden.

About a meter deep, they encountered, near the foundations of old walls, in a hiding place, old coins with teeth and bones of animals, fragments of knives, tools, iron nails, pieces of tiling, earthenware vessels, shards with a micaceous surface, a life-size stone finger, fragments of Venus Anadyomene in white earth of 1'. Winger, a piece of disc (diameter: 96 mm, thickness: 27 mm) in polished black stone, containing crystals in its paste (basalt or schist) pierced in the center a regular bitronconical hole (diameters: 12 mm and 22 mm), two curious spherical caps in glass, polished on their convex part (diameter: 76 mm and height: 40 mm).

There were 1672 bronze coins. The less ancient bore the effigy of Valentinian and date back to the end of the 4th century AD. ¹¹ ¹²

¹¹ Naturally, it would be necessary to do research because these stories take place at the end of the nineteenth century, the beginning of the twentieth.

¹² On a property in the hamlet of Moiry, commune of Saint-Parize-Châtel in the Nièvre.

© EÜREECALL

The others were by Gallien, Probus, Carus, Constance, Chlore, Hélène, Constantin, Licinius, Crispus, Constantine II, Constantius II. A part of these coins (less important) was housed (intentionally or incidentally) in a bronze dodecahedral box that was about 30 cm from the vase where most of it was.

Let's see this object in detail: at the 20 vertices are buttons, not quite spherical of diameter less than 10 mm. The 30 edges of the solid are about 27 to 28 mm, the thickness of the metal is 1-3 mm, its height is 59-62 mm. The 12 faces are drilled in their center; the circular openings have different diameters: they seem to be cut in the plate of bronze but there is no trace of beading on the edges. The smaller holes are circled equidistant engraved circles.

Let's look at their general characteristics: it seems that this is a delicate and neat cast iron job which could only be practiced with "lost wax." Dodecahedron heights range from 40 to 85 mm (this obtained for 32 dodecahedra).

The diameter of the balls varies from 5 to 10 mm. The circumferences concentric to the holes are in variable number and variable diameters. Small circles are arranged on each side.

We therefore found them in France, Switzerland, Hungary, Germany, Holland, England.

Léopold Hugo, nephew of Victor Hugo, published short excerpts from notes to the Académie des Sciences de Paris from 1873 to 1877 on beaded dodecahedra. It seems that the Academy never took their author seriously and it was only thanks to her uncle's recommendation that she agreed to listen to him.

In conclusion, it seems that among these objects, those which could be dated, date back to the time Roman Imperial; a number of them have been found in particular in the ancient camps neighboring Germany. The discovery of SaintyParizeyLeÿChâtel (Nièvre), makes it possible to better specify again and to assert that they were in use in the fourth century AD.

These dodecahedrons have intrigued their discoverers and many other people: their uses have been assumed to be very diverse:

scepter pommel

masses of arms

- brush
- chandelier
- cylinder gauge
- coin blank caliber
- game instruments
- ball game box
- variety of bilboquet...

It seems to be quite different, especially when we realize that there is an effect in the brain of someone looking at the constellation Ursa Minor through a beaded dodecahedron.

If we consider a hollow dodecahedron, beaded but whose faces are not perforated, it has a property interesting: everything is formed as if we had drawn the level lines of the scalar field $f(M) =$

20

j Y this creates the avæcum which is further amplified by the presence of the dodecahedron. If there are $1=1$ 1

holes in the faces of the dodecahedron so there are no level lines. If we place one of the holes against the eye and looking through the opposite hole at a constellation like the Little Dipper, the dodecahedron takes on the properties of the previous dodecahedron.

It turns out that by adding the balls with vertices of a dodecahedron, it becomes a powerful transmitter of avecum. It is somewhat similar to that of Boutard or Abbé Boudet [6] in linguistics and philology, they permute syllables, letters, make comparisons of phonemes between languages; this allows access to another very rich knowledge. That method could be applied in the countryside where one can easily by moving stones, change a landscape on the horizon. Eifs appear but also states, atmospheres and phenomena can occur by localization or delocalization. But also, this process can evoke new ideas in the person involved in this implementation. And this method can be applied in the field of the implementation of ideas. It's a very creative process. Forms will appear and be revealers. The people who especially criticized Boudet (there are had more than for Boutard because the latter was less known) absolutely did not understand his

approach.

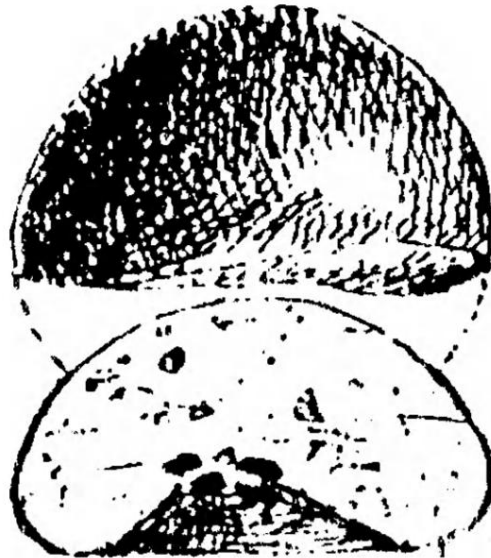

The philologists of the time of Boudet could not know the cerebral gait of the abbot; that approach may only work well for him and only with him, but let us insist, this process revealing, leads him to new horizons.

But pearl dodecahedrons have a remarkable property: they correspond to pathways in the sense where we talked about it previously: that is to say an F shape close to a pearl decahedron or on which we put one, becomes F' by a way. F with pearl dodecahedron -----> F'. This is very useful in radionics. Wires passing through a beaded dodecahedron take on special properties; depending on the metal composing the wire and the entry and exit holes, the wire is linked to Æ (æther) or emits eifs, yews, etc.

One can even associate planes with a pearl dodecahedron. These will be useful for transmitting remote information between 2 people each having such an object.

The strata (see [1]) associated with a pearl dodecahedron are not clear for their detection.

Let us point out a curiosity: the lenticular bases in vitreous paste.

Scale 1/2

The ruins of Moiry yielded, among other relics, two large pieces of coarse glass bases, opaque, blackish: one 77mm in diameter, 37 in height, well polished on the outer part of the cap; the second of 75 x 42, rougher and seeming to contain sand; some bubbles make its interior cavernous.

These very typical objects are starting to be reported everywhere, but we are not yet sure agree on their use. They are characterized by a spherical cap or flattened dome figure, whose convex part is usually perfectly smooth; the opposite side, more or less hollow at the center, looks like an umbilicus, so the section is somewhat bean-shaped.

Some authors have spoken of similar bases, among others M¹ Dumuys and M. L'abbé Harrdel.

The Nièvre provided three others: two which appear in the Museum of Nevers and the third belonging to M. de Flamare, archivist of the department and coming from Nevers itself.

A broken copy at the Auxerre Museum, one at the Blois Natural History Museum, two at the Carnavalet Museum (one light-colored and one black). Orléanais and Blesois provided several, among others in Roman (and Gallic?) burials. Picardy, Normandy, Poitou, champagne, also delivered some, almost always found in Gallo-Roman environments.

Mr. Demaison, in connection with a specimen collected at Reims by Mr. Mowat, thought that these pellets were used to grind colors and, according to him, several were found near old kilns of potters.

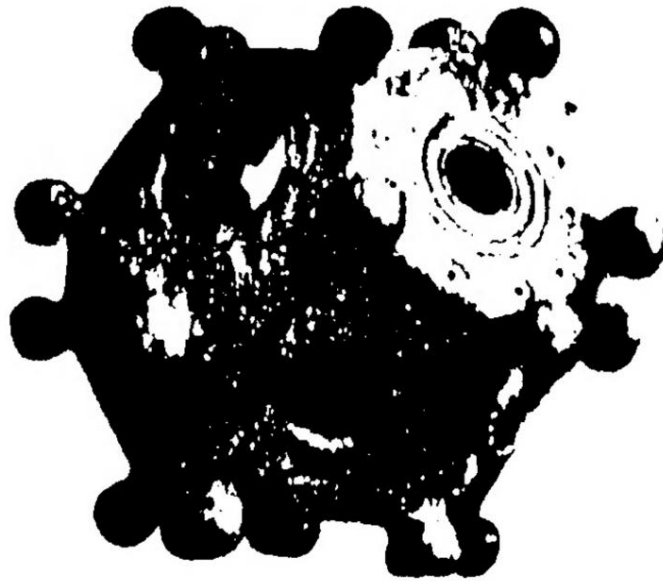

The Edinburgh Museum also has some and one is featured in its fine catalog (p. 274, fig. 148), or it is described as intended to luster or unite linen; the Museum of Stockholm contains some many, it is said, which come from, among other places, women's graves.

The Scandinavians see them as polishers and in certain provinces of their countries, women in were still used at the beginning of the century to iron the linen; it seems that it is the attribution that must prevail as the most probable one reads in a work.

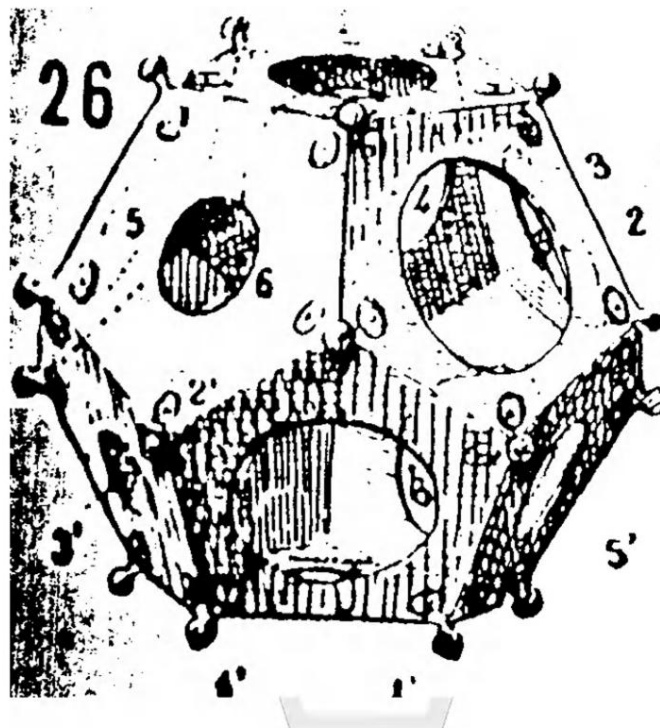

But this is misunderstanding the shapes and if you place this glass shape between the hands, it begins to emit what we call Z-fields, ZD-fields, and P-fields and likewise from the avæcum. The Ancients were very attached to form. 13

APPENDIX: II We still insist on a point of view that we evoked in the volumes let 2

[1]: that of the Representation.

To illustrate what follows, let us quote an anecdote: Near Angers, in the countryside, R. de Montery and P. Godart studied a place in which there is a menhir.

Note that the avæcum was found (detection with a pendulum or a rod) almost everywhere, this which Montery and Godart had verified. Montery noticed that there was no rain above the menhir; Godart confirmed this.

Shortly after, P. Godart discussed it with J. Ravatin and C. Glaudel; they found the avæcum above the menhir as in the entourage of this stone and the whole region. We is faced with a contradiction it seems? The approach of dowzers more or less RBB, that we most often encounter, would adopt the point of view of contradiction. Yet he happen to disagree. They would rather ignore each other than understand!

Is there a preponderant point of view on the other?

- the avæcum is not detected above the menhir?
- or the avæcum is detected above the menhir as in the whole region?

If so, should we use an artifice as indicated in [1] to choose one of the points of view? One artifice as envisaged by J. de la Foÿe does not change anything.

This is where we see the importance of representation. In the example we have chosen:

- either we are interested in the menhir then we look at the close surroundings, then the place in which finds the menhir and this is what R. de Montery and unconsciously P. Godart did.
- either you immerse yourself in the place and discover the menhir placed in this place; what J. Ravatin did afterwards, by transfer with three people present, C. Glaudel, G. Lhomme and R. Teichmann.

In this case, two representations are possible. The first, if adopted, allows us to affirm:

there is no avæcum above the menhir. The second, if adopted, allows us to affirm: the avæcum is above the menhir as in the whole place.

We are therefore faced, no longer with a contradiction, but with two possibilities of expression according to the representation¹⁴ chosen.

For example, how does the vegetation near the menhir look like? Does she choose a representation rather than the other? Note that with a form-revelator one can, while remaining in a representation detect what is found in another. One can, if one does not find an avæcum at the above the menhir, by a revealing form, to detect it. Another form that would not be a revealing form, would allow while being in the second representation, to pass to the first (it would rather be a form that reveals an absence).

Vegetation or certain plants or grasses can play a revealing role, which means that will detect on them what we find in a representation that is not the one we have chosen.

This experience lived with the avæcum and the conclusions drawn can be found with eifs.

For example, an eif, the V'e is in the countryside. Will there be an underground stream? this will depend on the approach of the representation, by the detection of the eif. If we find V'e it there may or may not be this stream. Naturally an underground stream is localized, but its existence still depends on approaching a representation that can contain the previous one, to be only a part of it or to be another one.

¹⁴ Representation does not necessarily mean change of C. of C. or in the other C. of C., change of R. of C.: Representation is the expression of the awareness of the cerebral approach which will take place in a timeline.

Let's see this in the following form: (The cerebral process, the awareness of the cerebral process; the way, the representation) has a halo: it is coherence in existence. The way is that expressed by the Tao. Representation is everything we choose to achieve coherence, in this whole there are the elements and their assembly. Afterwards, coherence appears, a coherence. We can give an image that will help to understand this concept: a child has a set of cubes and on each side of a cube is pasted an image.

The child must reconstitute a coherent image from the pieces of images which are on each side. In this example, there are six possible representations which will lead to six coherent images.

Let's look at another example¹⁵ : a jet plane flying in a region of the sky where we detect the avæcum; if we think the plane in the sky, after having tested the region of the sky in which the plane is going arrive, without thinking of the plane first, then we realize that the plane amplifies the avæcum around of him except behind him where the avæcum is erased. This is a representation. On the other hand, we can think the plane first and then test the region of the sky where it is. Think it before presence of the airplane, one finds avæcum, thinking it during, one no longer finds an avæcum behind the plane ; but in this case the avæcum is no longer detected, even after the plane has passed, whereas in the previous representation it re-detected itself after a certain time.

Chapter XVI Silence

Silence: it is interesting to dwell on this concept because it is tacitly understood¹ in the world common but quickly forgotten. On the other hand the poets have often evoked it and in our approach the poets have a great place.

We will often refer to a work by Max Picard: "The World of Silence" [1], and for quote a few passages.

In his introduction, Max Picard writes "Silence does not consist only in the fact that the man stops talking. Silence is more simply a state in which man can put himself when it suits him". He points out, which is very important: "Certainly, it is not when the word that silence begins. But it does not begin because speech ceases. It manifests only then". Is it underlying speech? Was the word hiding it? Is she like a form, she, on a background, he?

It is not in our language to consider silence as underlying speech, or speech erasing the silence. If, on the other hand, the word is considered as projected on the silence background, this can only be true in very specific cases. We will consider such a case later.

M. Picard ends his introduction with this:

articulate affirmations about silence. But we will only be surprised if we conceive the silence like a non-existent, like a nothingness. But silence is, it is a reality and speech can to articulate affirmations about all reality".

And again, he clarifies what precedes by "Word and silence are one: the word is instructed by the silence like the silence of speech".

Should we deduce from this a dynamic duality between speech and silence? Before deciding let's see Picard in a chapter he calls "Aspect of silence". "There is no beginning in silence or end... it is like uncreated existence". "It, (silence), does not grow in time, but time grows in him. It seems that time has been sown like a seed in silence, that he raises in him; silence is like the ground where time is fulfilled"...

¹ In the sense of - content and accepted

© EÜRECALL

We may be led to link the concepts of time and silence, which in rational C. de C.

doesn't make much sense, but in the other C. de C., it's the manipulation of concepts, even if these may seem totally foreign in the usual, which is an effective construction tool.

Let us continue to skim over Picard's thoughts: "Existence and action are one in silence. This is as if the trajectory of a star were abruptly gathered up into a single light: thus do a in silence, existence and action".

Let's stop at this thought. Let us consider existence and action projected onto a background, the occurrence silence. At that moment existence and action become a macron. Thus Mr. Picard described it very well without knowing the concept of macron. What he says about it is of the same kind as the image given in [2] where we involve a rider on his horse and the dust due to the gallop riding on the dusty path that rises in volutes and we "integrate" everything.

Let's come back to the concept: the delocalized, seen in volume 1 of [2]. The localized is existence with mark. There can be several types of localization according to whether one is in the usual C. of C. where there is only one or in the other C. de C. where there are as many as R. de C.. There are also localized very unstable linked to islands of incoherence. We have therefore postulated the existence without landmarks which constitutes the global; that is to say the delocalized. The passage from the local to the global is made by an escape from the landmarks, ordered flight, by a decalage, incoherent flight, by a channel. Thus from the localized, we were able to put in place the relocated.

The cerebral process which, of one has made it possible to postulate the second, is a certain course, a certain way:

localized.....--Q1Ç—> delocalized

Of a form F , thanks to this way, one could postulate Ext F . But the way, which makes it possible to pass from globally localized can be rethought in the opposite direction, that is to say from delocalized to localized. Thereby

2 Not every shape has an ext. On the other hand we can have different exts depending on what Ton is doing on F . Manipulations on F occur in the channel. This way is an unconscious cerebral step or even more often erased in the usual approach. The manipulations carried out on F as mentioned above, for example putting in holes of smaller diameters, obvious parts of the cerebral process. The way contains that within it. In reality its plating after transport of structures (localized -> global) on F makes that we reach Ext F

© EUREECALL

consider FExtF3 . This constitutes a form F . We're going to go from F to what we're going to write and name Int F. Thus we will write:

Int F <..... F '

We will have F which will be a part of Int F but Int F can be partly delocalized.

For example if F is the localized part of a human being, Int F will be this human being with its aura and what we see by the so-called Kirlian effect etc...

Back to the diagram:

localized----- → delocalized

Let us apply to the noise which is localized this diagram:

noise.....-Qlsÿ <—silence: silence is then the outside of noise.

Noise can be thought of as emerging from silence. Consider the reverse path: (path)'1.

localized <ÿ— ÎXSisX— delocalized

The Int noise will be speech.

Picard remarks: "...there is no longer any difference today between silence and speech. The silence is no longer a phenomenon for itself, silence today is only a word not yet uttered -

likewise there is no longer any difference between what has been acquired by research and what has not.

summer ".

And there he explains himself: "What has not been veiled, what is veiled, is also no longer a phenomenon. for itself, it is only what has not yet been acquired by research".

Let's study this paragraph. This is explained as follows:

Ext (what has been acquired by research) = what is veiled!

As in rational C. de C. the concept of ext does not exist, what is veiled is reduced to what is is not yet acquired by research⁴.

³ The sign U is taken in the mathematical sense of the term, i.e. F and both Ext F, considered as a new form Fÿ) .F and Ext F being 2 entity-forms so that one has the union in the mathematical sense).

⁴ Picard expresses very well the impoverishment of expression. Here, again, we realize the strength of the usual C. de C., its reassuring effect by its overly overwhelming logic, and the importance of putting in place the concepts belonging to the other C. de C. . to express coherences, that of poetry for example.

© EÜRECALL

When Picard speaks of the difference between - what has been acquired by research and what has not been - this difference is due to the fact that the two expressions are not in the same C. of C.5 or so they are both in the other C. of C. and in him there is a difference. This allows to see that the other C. de C. is richer than the usual C. de C.; it contains subtle nuances. Picard does not conclude that science is useful today but points out that "...there is no more in science today's real encounter between man and object".

We have seen that the outer (which has not yet been acquired for research) is what is veiled! Because that this ext exists, we can deduce from it that the man if he is in front of the object that he does not yet know or a new phenomenon for him, then:

the ext[(New object or phenomenon) U (what is veiled from the object or phenomenon)] = what is does not yet know of the new object or phenomenon.

But where does the Encounter between man and object take place? The Ext (what we do not know about the Object or new phenomenon) = Meeting between Man and Object.

Silence, outside of noise, can be further deepened. To see this, let's go back to Picard: "...the cathedral... it is like the solid entrance to a well through which silence descends into a silence even deeper..." and "...the silence of the cathedral which leads to the silence of the spirit".
"The cathedral... enormous reservoir of silence".

The silence of the cathedral behaves towards the silence of the spirit like the growth of sheet [2]. We are facing an AG6 system [2] where we have the cathedral (F!) and the silence of the cathedral (F2), the first the parent and the second the bait which are in equimsey. Consider a human being, that is to say the obs, who enters the cathedral.

The Voiloc de l'Obs is diluted in F2 and

$$(F1 \cup l'obs) \mid F'2$$

From where

$$F! \mid F2 = F$$

$$(F1 \text{ and the obs}) \mid F'2 = F'$$

5 is the change of state from F to F'. Ext S is the silence of the mind.

ÿ If the two expressions are in different C. of C., they are not comparable, and yet we speak of difference. This means that this "difference" can never be bridged.

6 System AG = Primer-Progenitor.

7 We will see later what must be expressed correctly.

© EUREECALL

Picard says: "The cathedral is like silence encrusted in stone".

The inlay is a position of 2 bodies A and B, more generally of two shapes A and B, what fact that we can write:

the cathedral (as an entity) is the halo of (the stone, A; silence, B) where A is encrusted by B

Consider the concepts of obverse and reverse of a coin. Are they in Dd? That depends on what you consider. From the moment we become attached to the shapes of a medal, we cannot speak of one without the other; this is not enough to put them in Dd But we can consider the obverse as emerging from the rest of the coin and the reverse likewise. But we don't have the obverse which emerges from the reverse and vice versa. So we don't have a Dd Here the 2 faces are two limits inseparable from a fairly flat cylinder. If we consider the system as described thus: the obverse and the rest of the piece which will be called reverse, the reverse and the rest of the piece which will be called obverse, then we will have a Dd between obverse and reverse.

One can choose another representation of the obverse and the reverse: they can be considered in equimsey. They are then the emergence of a third delocalized term. themselves are not necessarily completely localized.

Picard thinks that speech came out of silence and even better "out of the fullness of silence".

"This plenitude would have exploded by itself if it had not been able to flow into speech". let's see

First, what does this plenitude of silence correspond to? This is the state that the Obs takes bathing in the atmosphere created by a T AG system: the Obs will project itself into a T AG system and the silence, and the two will overlap; there emerges an atmosphere in which the Obs bathes. We see here that the Obs. does several things at the same time: it projects onto a T AG system of which it has the concept, places itself in one of the cells of this system, becomes impregnated with the atmosphere, it reveals otherwise^{8 9}.

This is reminiscent of a decal type shape. To obtain a decal type shape¹⁰, we start from a form F, which is projected, soaked with a liquid or an atmosphere for example, and which is revealed afterwards, following a form F'.

⁸ We write A embedded by B: A 0 B.

⁹ This is one of the purposes of initiation. Most of the initiations did not have a TAG-like gait for the brain. They were too little studied for that.

¹⁰ Decal in Hebrew: H Sh hA Th - Th MWNW Th.

We have thus gone from F to F' and F' is said to be the decal of The path followed is called the process of decal type. We see here that diving into the cells of the TAG system, imbibed in a atmosphere, that of the TAG system; we therefore have a decalco-type approach.

Picard affirms that silence is a primordial given. For him, man contains silence. the silence is related to the global as the ext of the noise. Man, when we speak of the entity man, this entity has an ext and an int, is embedded by silence (embedded as seen previously).

And Picard presents aspects of silence. By succinct comparisons he makes impressions that we can have silence. This succeeds because silence is both primer and progenitor. The silence is AG type. Picard writes: "In silence, man finds himself... face to face with the first beginning; everything can once again start anew... At every moment, the man can, through silence, be at the first beginning". Picard's approach is full of caution; its short sentences take you step by step, so the reader gradually absorbs the depth of Mr. Picard's thought.

"Connected to silence, man not only participates in what is original in silence, but to all that is original. Silence is a primary phenomenon that is always available to the man. There is no other primary phenomenon so present at every moment as is the silence". It should not be inferred from this that silence is the only entity which by itself is of type AG. But silence encrusts man, so by this position of two forms Man and Silence (Silence 0 Man), Man becomes impregnated with the properties he feels in silence. It is said that the silence is in itself an AG system whereas previously when we spoke of the silence of the cathedral, the cathedral had been placed as a progenitor and silence as a primer. All this is not in contradiction. The progenitor cathedral is in equimsey with silence, {AG system}, primer. It is the silence in equimsey with the cathedral that is called the silence of the cathedral.

Picard thinks of silence as a primary phenomenon. For Picard, primary phenomenon: given first that cannot be reduced to anything. It (silence) cannot be replaced by anything else.

Let us consider the set of primary phenomena: in this set Picard places love, fidelity, death, life. If we apply silence to this set considered as a background, we will have a halo: it will still be silence. Silence is its own halo, its own depth.

Silence is truly mysterious. The other primary phenomena, love, fidelity, death, life, are encrusted with silence. "There is more silence in them than outward manifestation" ... « il ya in love, in fidelity, in death more silence than in general, does not appear

© EUREECALL

of love, of fidelity, of death. There is also more silence in a man than he can use.
in his life. This is what makes any manifestation of man mysterious.

On the concepts developed in volumes 1-2 [2] and all those that have been implemented in [3] and [4], we can introduce those of evolution and transformation, even if time is not present in this ocean of concepts.

For Picard, silence emerges from noise in today's world. It gives movement to this emergence "...like something that goes back to the earliest times...silence...like a primitive animal...living"...and this emergence takes place as if the animal were hiding by sinking more and more noisy. It must be understood that this emergence in the noise (in our modern world, and it does not correspond to what silence was long ago) described by Picard presents himself as a presence immersing himself in noise; there is no contradiction between emergence and immersion in this precise case because everything happens as if, little by little, the silence, from its primitive position had moved and found itself present in an immersion. This silence of today carries with it the memory of the silence of yesteryear. It is still the silence of yesteryear, the only silence, it simply presents itself differently, but as it is its own halo, it his emergence-immersion of noise is reflected on him and there appear two components of silence, the silence-starter, silence-progenitor. This is why Picard writes "You can still see the broad back of the silence in the thickets of noise". It seems like the silence is sinking deeper and deeper into the depth of his own silence); the depth of silence is its halo which is itself, but the effect of the emergence of the noise which manifests itself in an immersion in a part of the noise, plays on silence, AG system on its own. It therefore seems that the usual C. de C. acted on the silence having destroyed its unity, then makes appear two components, like those of the avæcum, where there is had, if we take a representation, a sinusoidal component, colored red-orange, moving in translation, it is component A, and the other dense, gray mass, it is component G.

We also have (component A of silence, component A avæcum; component G silence, component G avæcum) has a halo: it is the density¹¹ of silence or of the avæcum. This density is such that Picard points out: "However, all the noise today sometimes seems to be only buzzing of insects on the broad back of this animal of silence".

¹¹ But density linked to the notion of gravity (not fertilization or consequence of fertilization).

© EUREECALL

We have seen that we have used the concepts of evolution and transformation in the delocalized: transformation of silence as it was before, evolution by sinking into itself through the appearance components A and G., silence being the equimsey whereas before it was a unity. It would seem that the modern world has made it possible to make silence more explicit by becoming aware of its two components of which the equimsey is itself. The rational world, if seen from the other C. de C. allows the obs, to move (by thought) to take relative positions of a C. of C. vis à vis on the other, to formulate what perhaps the Ancients had not attempted to establish, or perhaps superficially, or without realizing it.

We have seen that Int noise = speech.

Picard points out "...that today the silence is diminished...". This is true if we stay in the C. of C. usual; which, moreover, erases any other point of view on silence. Yet we have just seen that the use of the two C. of C. makes it possible to realize that this reduction gives birth on the obverse and reverse of a coin. We have seen several possible interpretations of these concepts:

- they are described as emerging from each other.
- they are in DD
- they are in equimsey.

Picard writes "Speech, verso of silence, silence, verso of speech"

12

We can therefore construct

(Speech, silence; obverse, reverse).

This has a halo, but this halo will depend on the three possibilities above which give possible connections between obverse and reverse. There will be three possible halos:

- in the first case speech, image of silence and vice versa, but there is between speech and silence something; the halo will be: Dynamic Duality. Obverse and reverse are described as emergences.
- in the second case, speech and silence are in Dd; the halo will be the flow. Obverse and reverses are in Dd 12

12 Picard adds "In each word, there is something silent that indicates where the word came from; in each silence there is something that speaks and indicates that speech is born of silence".

- in the third case, speech and silence are equal; the halo will be: deployment.

Obverse and reverse are in equimsey.

Silence is still this: it is the atmosphere of chaos.

Consider the notion of formless. It seems that the organized form emerges from the formless. In the organized form appears a coherence. Ravatin in these courses spoke of formless. The shapeless form is the form that is not organized.

Let's do (organized form, shapeless form; obverse, reverse).

This can have different halos depending on how the couple was considered [obverse, reverse]
. Suppose this couple described according to the first ^{rx} case.

The halo of: (organization, shapeless; obverse, reverse) is what has already been called the couple (emergence, immersion): what makes the previous aureolar the couple (emergence, immersion) applied to the shape. In the couple (organized form, shapeless form), let us not retain for the moment only the second term: form-inform. Consider form over substance, the formless and let us place the form on the formless, we are going to have a halo: it is chaos. Naturally we could continue to play and manufacture (form, chaos; obverse, reverse) by imposing the presence of the couple (obverse-reverse) and for example according to the first way in which this couple was envisaged^{13 14}. There is a halo that we do not know.

We could have considered couples (obverse, reverse) according to the second and third ways, (organization, shapeless; obverse, reverse); we fall for the aureolaires on concepts to which it does not correspond to any word or expression in the French language.

Let us continue to study Picard's text step by step: "It is only when a man speaks to a other man than this one learns that speech no longer belongs to silence, but to man; it's by the *you* of the other that he learns it; it is only through the *you* that the word fully belongs to man and no longer to silence". Picard insists a lot on the *you*, which he has written in italics. The others are in the C. de C. de l'Obs.

¹³ Note that we pass from the second case to the first by a flight, which is another way of approaching the Dd.

¹⁴ In the process (A, B; C, D) there is a pair which is in relative position; he imposes this position on the other couple and this gives the fifth term: the aureolar.

So when the Obs. receives the word spoken by another, he detaches it from silence. This happens when the obs places the others (who are in the echo of his C. of C.) as equivalent to him. At this moment it disturbs what we have put in place in all that precedes.

Let's project the word on the silence background, we will have a halo of the word (what Picard calls the depth of speech); it is thought._____

Picard, further on, considers speech to be born of silence. We must therefore consider the process inverse of the form on the substance. To flatten the form on the ground is to make a journey of what is at foreground to background. Let us rather bring the substance over the form. In the case that interests us, we brings the silence background to the speech form; we are going to have a halo: here it will be language.

Picard says "Silence can exist without speech, but not speech without silence". It's not because we will have constructed silence as the effect of the path on the noise that silence is not first. Simply by this process we construct concepts from the localized. Those process of obtaining concepts from the localized are more fundamental for the notions same firsts. To take a comparison in the usual C. of C., in mathematics, it is as if we gave ourselves the operators before the sets on which they act.

"Speech would be without depth if it lacked the background of silence", that is to say that the halo of speech in relation to silence, that is, thought, is existence before being formulated as we present it here. The formulation is necessary to set up a formalism which will allow us to go much further. So we build a world of concepts.

When it is important enough, it takes on a new character, it is an existence primordial, even more, it is an existence "before Creation" to use the expression that Picard applies to silence without speech "Silence without speech is of the order of what precedes Creation, he is an unfinished Creation... It is only by the fact that speech is born from silence (one saw what was meant by this expression), that the silence passes from what precedes the Creation, in Creation, of what is not historical, in the history of man, in his proximity ; it becomes part of man and a legitimate part of speech...". This world of concepts as it grows, takes place as an existence. This confirms what we had already hinted in [2], that our approach must be dynamic and not static as when one evolves in the C. of C. rational. Thus the establishment of this world of concepts is to the domain that one approaches, what silence is to Creation (world of concepts, area being addressed; silence, Creation) at a halo: the world of possibilities.

© EUREECALL

Next Picard "Possibilities that are not realized are food for silence; by them, silence acquires more strength and, in turn, becomes powerful nourishment for all that is do otherwise".

We will not say that these possibilities will never come true, however we can bet the existence of such possibilities but they are strange. Is there a R. de C. where they could be realized, or even an island of inconsistency?

Then can we speak that this set (if it can be a set) of possibilities which are not not achieve in islands of incoherence? Because we are aware of this "together" we can build something else taking into account these possibilities of which we are aware and which do not realize (this explained outside of a duration) then of those of which we are not aware and of which existence is thought. They are going to be overlays on the silence, which means that even if we removed the silence they would remain. In some of these possibilities that are not, there is incoherence, which means that we must remain cautious when approaching silence.

The R. de C. are diluted in silence, even islands of incoherence. All points wanderers who move on the straight lines of the diagram given in [2] and [3] constitute biblical chaos.

We will immediately see a new type of shapes: diluted shapes. They are not representable.

they exist as contained in a form that is generally delocalized. For example,

consider a two-dimensional network, with square meshes, or parallelograms or others.

A UFO, as long as it is not partially located, is a diluted form in such a network; there is will be of several types. This network is an incrustation in the usual C. of C.. We can have a form of an island of incoherence, which is diluted in an incrustation-network and which can be localized (partially)¹⁵. A network is associated with the human being - it is on a surface, it is what we have named in voiloc [2] and [3]. The equimsey of the form on a background, this gives the functionality. If they are localized, it is generally an OT If some are delocalized, it is an OP

¹⁵ Forms are diluted into networks. From the networks, forms can emerge if they are solicited by something else.

By imposing these features, we often localize . This will cause that between T and U 16 there will be a transfer, or a collapse, finally a new entity more or less localized and more or less stable TU can form, we could even have a halo

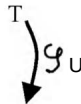

$$(T, U: \otimes, 0).$$

But we can still have the schema where U does not yet exist but where we have:

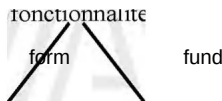

$$ty \cdots \cdots \cdots \otimes$$

©

The following phenomenon occurs: T evolves according to a story or a U is created directly and afterwards we can fall back into the previous diagram

Naturally for people in favor of the ternary they would see one in

But making ternaries does not look like much especially when the 3 terms are not equivalents.

Consider a form T or a system T. Consider a non-localized concept 0 such that we have

$$\backslash \cdots \cdots \cdots \otimes$$

where the arrow can mean the reverse way $\cdots \cdots \cdots >$ or a projection or another concept.

Let us give U similarly in gender to T and (Q) similarly in gender to 0 .

To 0 and (Q) can be

associated states, for example. But it may be that between U and 0 there is no connection. Between 0

16 Where T cl U are OT or SV for example, and © is Eext of EO.T. T with its functionalities, or the exl of the SVT with a background, the possibilities are endless.

© EUREECALL

and @ can occur a Dd, an equimsey, a projection of Pun on Pother, a detection of Pun in Pautre, overlapped by Pautre, etc... Thus we will have a diagram like

$$T\ddot{y}-----\textcircled{c}$$

$$u\ddot{y}-----@$$

“UFOs” can come from overlocalizations due to the multiplication of OTs. The localized features become overlocalized. The OT thus projects itself onto the background which is a neighborhood in which it is located. At that moment, this fund and this OT are diluted in a network which is an overlay of the local. This overlocalization of functionalities leads to the creation of states of the kind |K Sh Ph> with reversed Shin and even with other characteristics.

We can also have effects on the SV1'' . Very localized functionalities can create states of the type |K Sh Ph> because, for example, the OT can stick to the bottom. The ext OT and the functionalities go into |K Sh Ph> state.

Thus can occur a process that will be reduced to the following diagram:

$$\begin{array}{c} \text{SV M}-----\text{Ext SV with bottom} \\ \\ | \text{ transfer} \\ \\ \text{OT}^{\wedge}-----\text{Ext OT and features in state} \\ | \text{K S'h Ph} > \end{array}$$

and creation of a new system

$$P) \text{ Py} \quad i$$

The content which only exists because there is the form (the content changes as elaboration of the form) is made up of leaflets. Consider an OT. The OT dislocates these

17

17 VS: Living Systems.

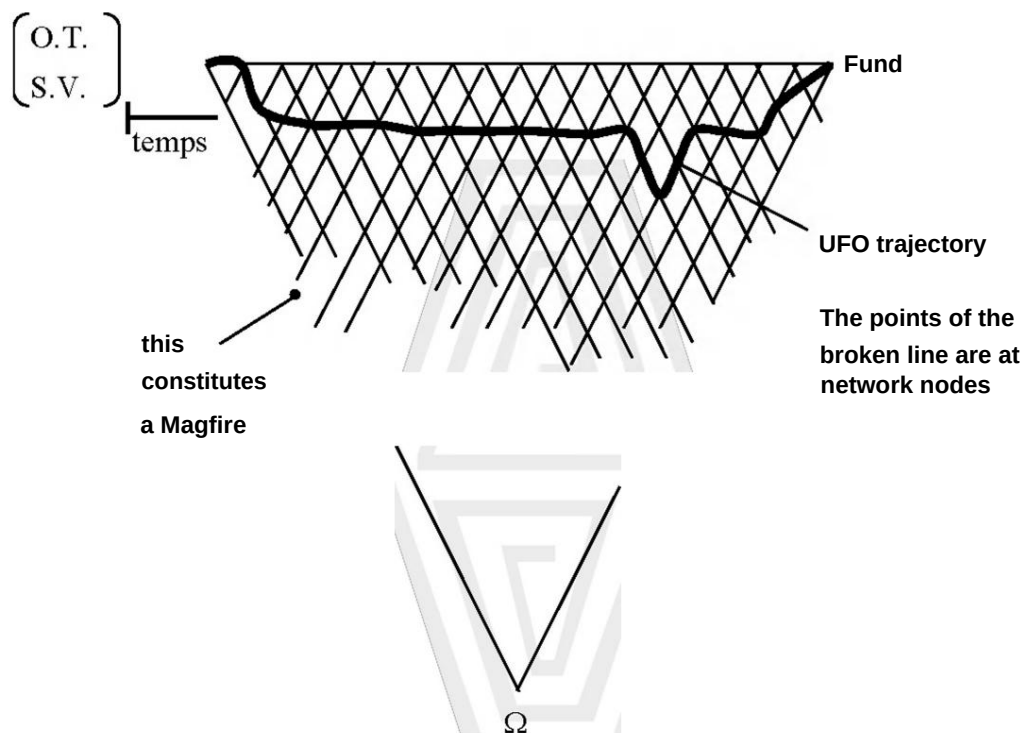

We recall OT: technical objects
OP: Phenist objects.

© EÜREECALL

sheets and brings them to collapse, we then have a magfeu [2]. The magfeu is diluted in our physical universe, then an island of incoherence can come out of it, the trace of which in the usual C. de C. is a UFO. But of course all this is only one possibility among many others. The OT can not have an ext (a steam locomotive considered as all of its parts does not have from ext; the same for an electric locomotive. If the steam locomotive is considered a everything, it has a slight ext primer). The ext can come from a set of OT, or from a neighborhood of this OT or of the coherence in which the obs places the OT

To carry out an OT is to provoke an emergence. On certain funds, the OT can project and give a macron OT[^] time, [2].

The bottom can also come on the OT. If Q is a landmark leak as we saw in [2], it the following case may arise: As in the case of the Basque pelota game presented in the volume 1 of [2], we have two scales.

Between Q, the r_{OT}^{SV} , the background and the two scales, a network is created; the trajectory of the UFO is an emergence of certain nodes of the network.

© EÜRECALL

Here for this attempt to explain the UFO phenomenon, we did not involve the polaror as in [2]. This attempt can replace or complete that of volume 1 of [2]. He is also fundamental to refer to [4].

Oracle's response to Croesus

Chapter XVII

GNOSTIC DOCTORS AND THEIR SYSTEMS

This text is added to the understanding of the work of L. Boutard and A. Hatinguais, but the presentation is made to relate a little to the mode of expression and the representation of occultists. According to Simon of Samaria, at the summit of entities, that of fire, infinite power of all aethers and states of heat. This power to act goes into action. To express his thoughts, Intelligence named it and having named it, it was able to unite its different ideas and form them a whole. From this all were drawn six beings or emanations of infinite power. These beings were obtained by syzygies: two by two active principle, passive principle. Simon also had the six aeons of superior.

+	We (mind)	Epinola (thought)
+	Phone (voice)	Anoma (the name)
+	Lagismos (reasoning) - Enthumesis (reflection)	

In each of these six aeons or primitive beings (nixaïs), the infinite power was found entirely in "potency" but not in "act". To pass into "action", it is necessary to make an appeal to an image which conforms to what is expected of infinite power by an "image". For this, the aeons themselves became emanating principles and six intermediate aeons were created. Finally in the terrestrial world took place the actual material creation according to the law of similarities which says that all beings in a particular world develop in a manner consistent with that in which developed the upper world and that all beings in each world themselves have the fiery desire to instigate what their superiors in the emanation hierarchy are doing. The desire set execution leads to the principle of the fall.

Energetically, the principle of Gnostic generation is always the same: the active power enters into communication with the passive power, deposits therein a germ which is only a spark; the germ grows and develops according to image and likeness. The Doctrine of Basilides of Egypt complements that of Simon. At the top, the god who is not, the nothingness that exists "ο © x onthéos" (which can become something), passes through internal action in God called Giotés, of triple essence and of triple activity; under its action, there is a first emission (Katabolé) which is, which becomes the act.

The first rises to the pleroma; the second (carried on the wings of the Holy Spirit) reaches only limits ; the third remains in the germ of the world: for it redemption is necessary.

Thus the upper world is created. The intermediate world was then created by the union of this germ of the world and the treasure of all the seeds: the great Arkôn was born enthroned following the world superior. The basis of God's nature is Love, and Love cannot do without

to like. This Arkôn generates a son. The link where these mysteries were realized is the agdoade which extends to the moon where reside the principalities (Archai), the powers (Dunameis), the dominations (Exausiai) and three hundred and sixty five gods ruled by the great Abrasax (corruption of the great Hebrew blessing (la Barecha (from Berech: to bless)). Abrasax can be given either etymology: Al Braxas (the stone of blessing), or from "abra-q-ad-habra" (meaning: "Send your lightning until death"). From this world of Ogdoade emanates a whole other world which reproduces the first according to the principle of similarity. There was thus a second dominating Arkôn of the space where we live; where is the potentiality of all possible germs. But the beings emanating from a world cannot conceive of a better world than their own. The second Arkôn did not know the first and wanted in turn to dominate the geniuses. They resisted him and it was a terrible struggle.

Valentine of Alexandria humanized the teachings of various Gnostic schools. Emanation is the basis of his system. In the intermediate world the Prince is the "Demiurge", "The Elder of Days ". The material essence has another prince: Diabolos; the spiritual essence has for prince Beelzebub; the Demiurge is stupid and "coarse"; while the divine wisdom Sophia acted and created, the Demiurge believed that everything came from his hands and imagined himself to be God.

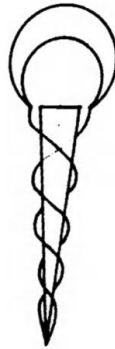

Valentine definitively establishes the Gnostic science of the pantacles; fate depends on powers that preside over acts; as for the acts themselves, they have no influence, they only indicate the strength of the dominating powers. For Valentine's Day seven planets enter the twelve signs of the zodiac; the rising of these planets is directed by the powers. They indicate the movement of matter. There is often a struggle between the powers.

In pantacular Gnostic science, in addition to the "name" (the name is the thing), source of the power of the pantacle, appear the respective representations of the god, the angel, the daimon evoked as well as the symbolism of the planetary hour.

The Gnostics modified what seemed to be usages and brought very operative elements. specific, new and important. Tables were set in a strange looking way by the neighborhoods of names: Yahvé, Adon, Sabaoth, Michel, Osiris, Isis, Anubis...

© EUREICALL

angelic par excellence gave the general name of the Gnostic stones found. The name of Abraxas was associated with figures, the most frequent of which was Anubis carrying

The inscription of Mil and Asia Minor, published by Le Bois in 1847 gives the correspondence between the set of Greek vowels and an "energetic" sphere of action linked to seven planets, satellite (the moon) and star (the sun). The planets were:

Saturn
Jupiter
March
Sun
Venus
Mercure
Moon

The 2nd century Gnostic musicographer Nicomachus of Gerase says: "The sounds of each of the 7 spheres produce a certain noise, the first making the first sound, and these sounds were given the name of vowels... The Theurges invoke the divine by slapping their lips, *whistling*, *sounds* inarticulate without a consonant. It is the brain configuration of the human being that creates *the* relationship between the sun, moon and 5 planets and sounds. The human being, by his thought, arranges in a representation given the matches.

The seven-stringed Greek lyre (heptachord) is mentioned in papyrus W of Leyden¹⁸ and in the "Mimaut Papyrus"¹⁹. One establishes the correlation by chanting of seven vowels with seven *virtues* or powers.

Seven metallic principles preside over it with 4x7 moonlights in seven intonation sounds. The Gnostic incantatory formula will be:

Pronouncing towards the West, the right hand extended towards the left and likewise the left towards what is to left, you will say A; towards the North, the extended right fist, of the say E; extending both hands upwards noon of say H; then towards the south, the hands turned towards the stomach, you will say I; spitting on the ground and touching the extremities of the feet, you will say O; looking up, hand on heart, you will say y; looking at the sky and with both hands on your head, you will say Q.

The magical papyri which have come down to us indicate a constant use of Greek vowels in both as vocal notation and as a sacred syllable, but also as an indication "energetic".

Note: It would be hasty to identify the Boutard atoms with the atomic nucleus and the electricities with electronic cloud; one cannot reasonably confuse the process arrangement of the little serpents with that of the N, O, P, Q electron shells; moreover for the iron and copper, we only have the N layer.

All one can do, if one follows the Gnostic theory, is to note that the world of matter (of the fall) is the imitation of a process of which only the prototype material is the primary form (arkon).

Amplifying generator: While the truck represents the element
fundamental of the automatic generator, the crescent of steel is that of the

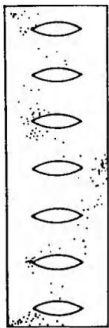

amplifier generator

U. _ Following the reading of the abraxas, the truck

carries a small snake ^ whose head rests on the sphere of the truck and the doubled snake is carried

double winding on the crescent. The heads meet towards the center, at the belly of the crescent,
the tails being directed towards the tips; the croissants are fixed on a strip of leather, the bellies
on one side, the spikes on the other.

attract F Aether leaving if the
iron is shiny and polished

,Loving the Aether

Copper collects red atoms

Brass collects yellow atoms

Lead collects blue-black atoms

Mercury promotes the disintegration of the Aether by attracting the blue-black atom.

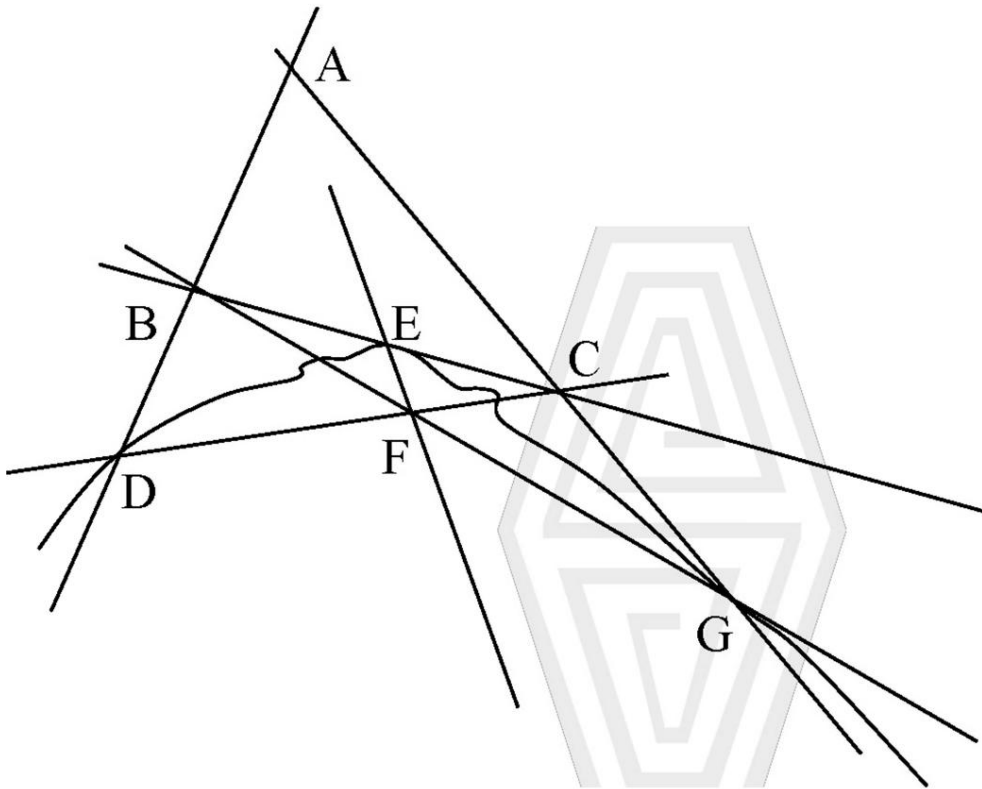

The goal used for Boutard is to dissociate the Aether and to draw from it the elements of which one expects a energy by collecting male atoms and female electricities, using conductors appropriate.

Chapter XVIII

Complement on the use of some projective geometries

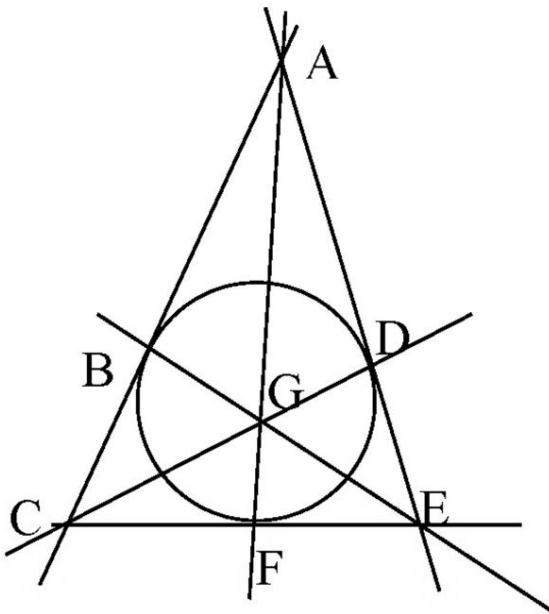

We are interested in finite order projective geometries. We refer the reader to numerous books and articles relating to these subjects. Ravatin realized that if we detected the avæcum around the shape given by the chosen representation of the projective plane, this does not⁹¹ did not depend on the representation. The representations are made in an ordinary plan but the lines have only a finite number of points.

Example: the plan of order $k = 2$. It has $k^2 + k + 1 = 7$ points and 7 lines. For each point it passes $k + 1 = 3$ lines. Each line is made up of $k + 1 = 3$ points. Here we have a possible representation.

²¹ For eifs, it may be different. The term representation is taken in the sense of a figure drawn in a plan.

Other representation:

: To determine the eifs, it is necessary to make the lines with metal wire or even string, and the dots are spheres hollow. This projective plane of order 2 thus realized emits a very strong avæcum. He has an ex. There are way to use pieces of blueprints projective only by perforated plates: part of the representation is on a plate, the other on the other plate. We hold both plates separated in the same plane and we place shapes between these two plates.

For example, with such an assembly starting from the projective plane given in the previous example, we transforms any form into a perfectly stable transmitter of avæcum.

One can use several projective planes either represented by hollow spheres and wires, or holes drilled on plates, or you can add engraved lines to these plates.

By having projective planes of order higher than 2, we have interesting properties when points belong to the same conic or the same oval. Also there is no point in look at the points and lines which correspond to each other by translation, reflection, dilation.

Moreover, configurations like that of Desargues are to be sought in certain cases. From 99 constellations can be considered as parts of projective planes. A transfer is then established between the constellation and one or more projective planes.

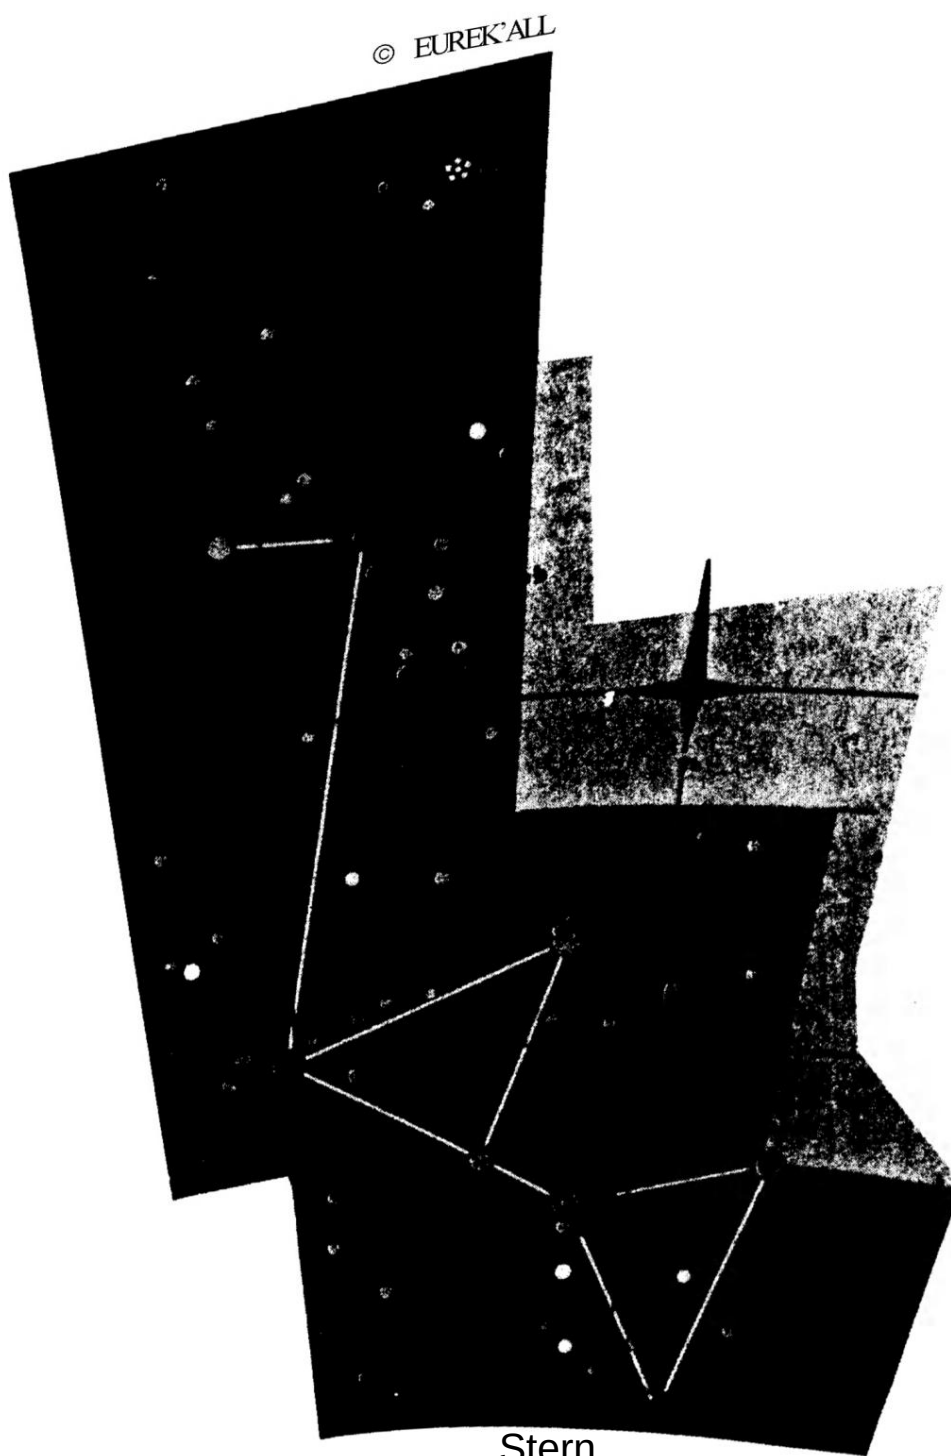

Plans of order 2, 4, of order 9 are interesting. Plans of order 15 are even more interesting. Their realization and study are very delicate.

The projective planes of order 15 or 16 are linked to the psyche of the human being [2].

22 The constellations which are to be considered are those of the Ancients. On the other hand, it is necessary to pay attention to the fact that certain constellations of the ancients have been transformed: example: that of the "Vessel" which has been separated into three:

The Hull - The Stern - The Sails.

The Ship is attached to the Nave of the Argonauts. It is therefore necessary to work with the Vessel and not one of the three constituting it.

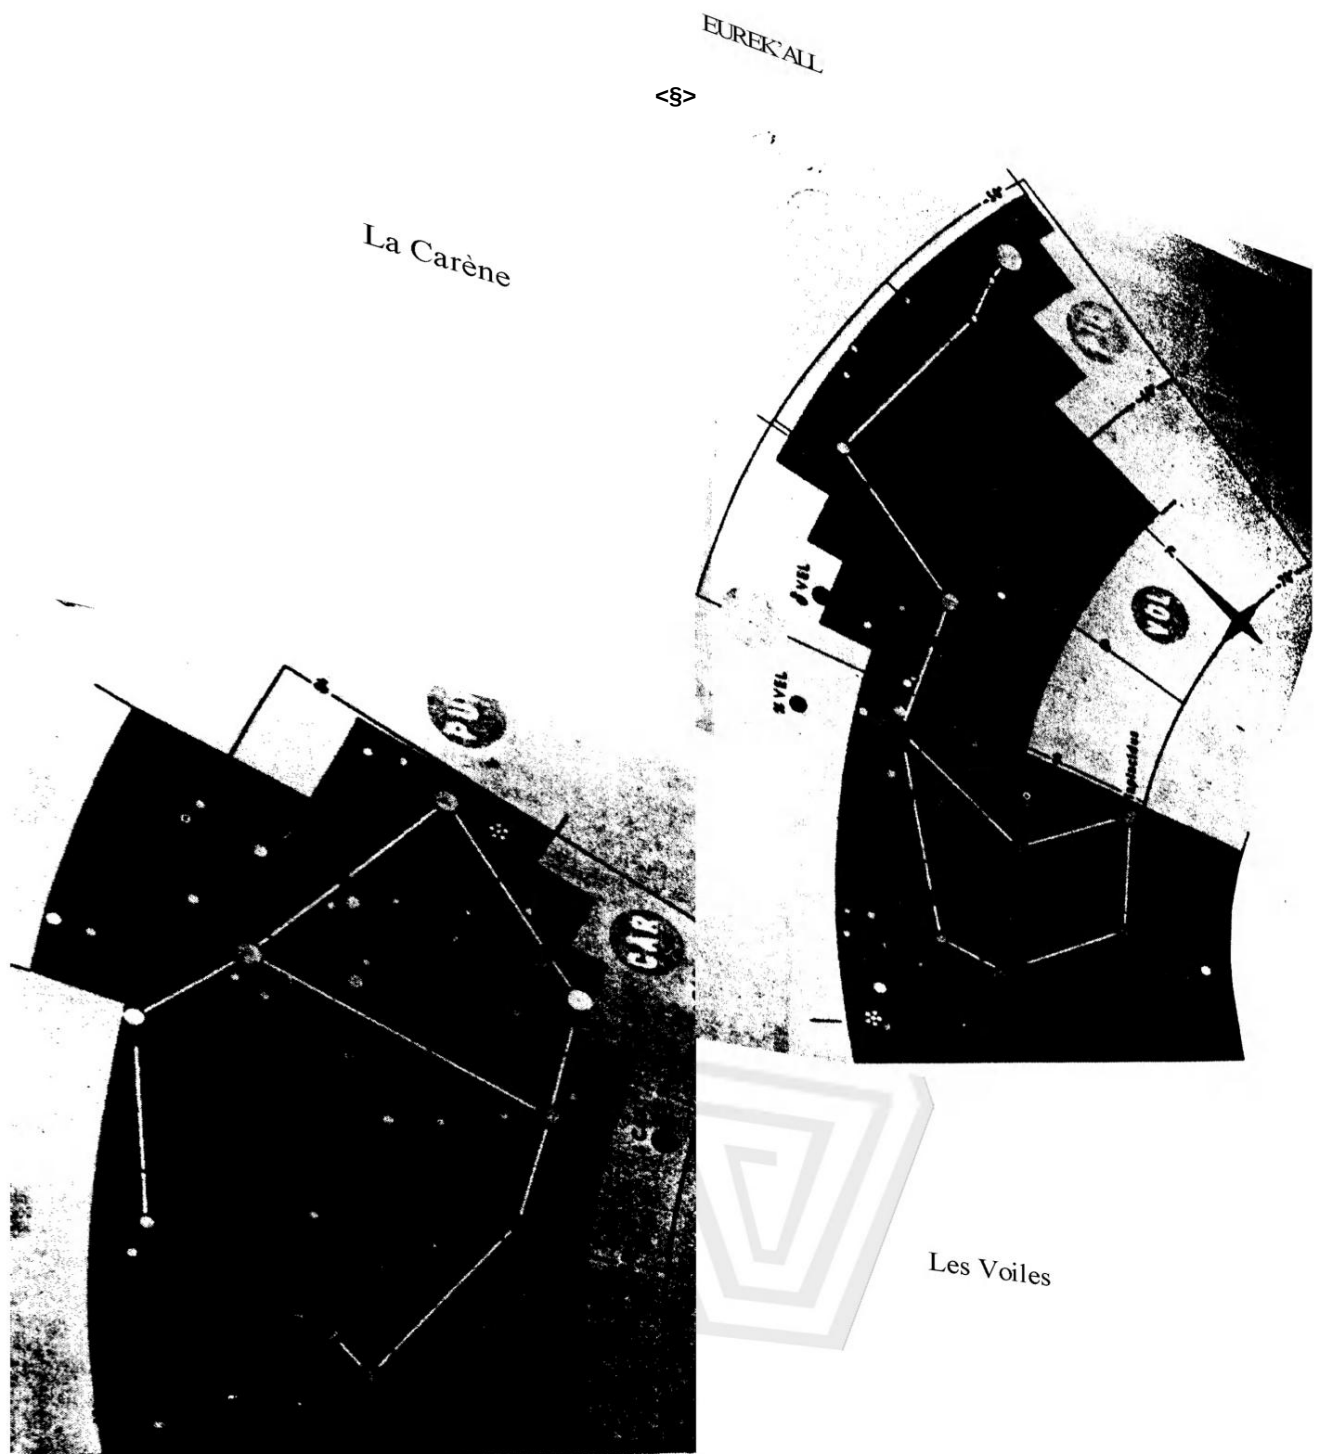

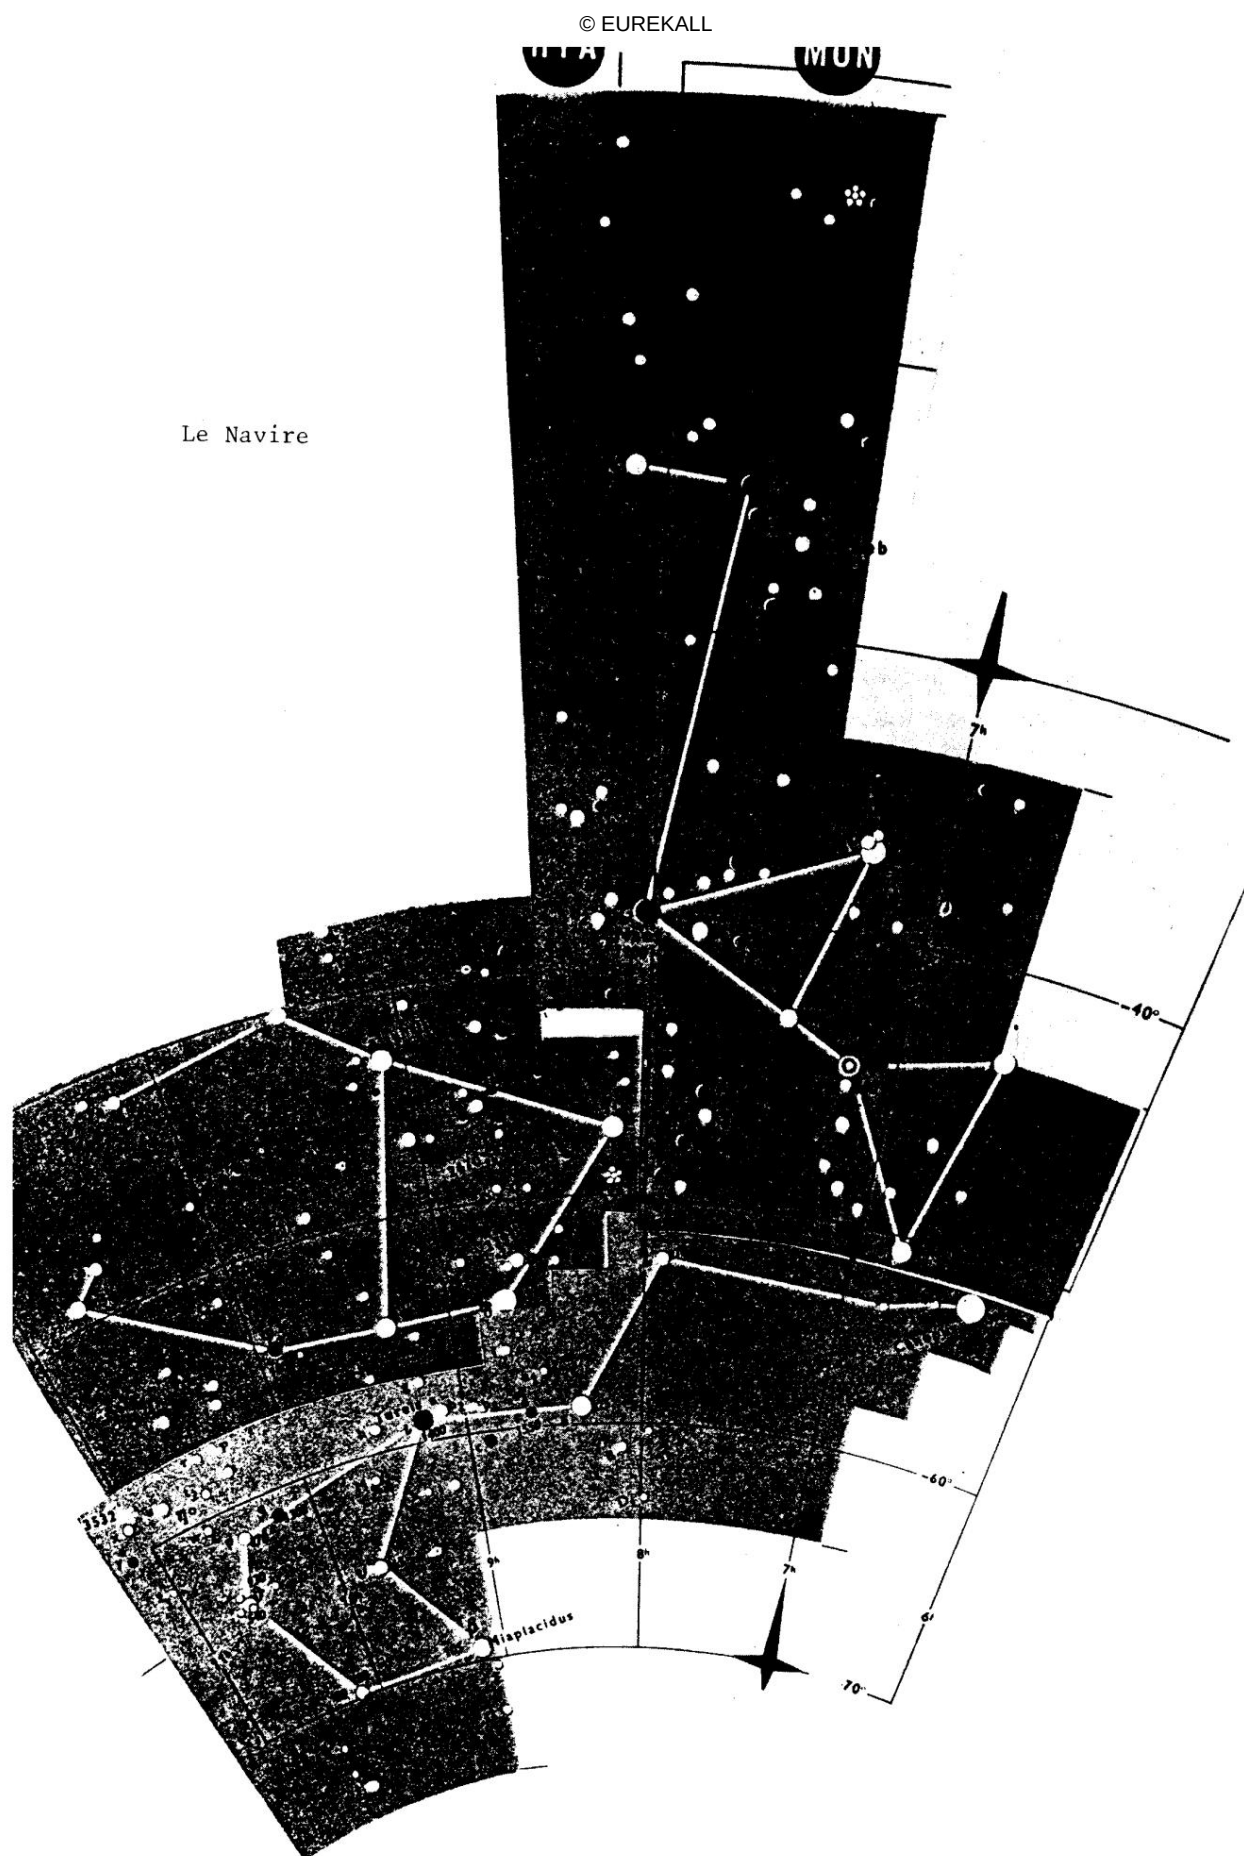

Stern

These diagrams are drawn from the Illustrated Atlas. Constellations by J. Klepesta and Paris (1968).

Bibliography

- 1 Max PICARD, "The World of Silence", Edit. PUF, Paris (1954).
- 2 Vladimir ROSGMLK, "The Emergence of Enel or the Immergence of Landmarks, Introduction to the Study of Forms and Fields of Coherence », Volumes 1 and 2, Edit. ARK'ALL, Paris (1985).
- 3 Jacques RAVATIN, ARK'ALL Common. Flight. EX, do. 1, 141-154, Edit. ARK'ALL, Paris (1986).
- 4 Jacques RAVATIN and Anne-Marie BRANCA, "Theory of Forms and Fields of Coherence, Edit, du Cosmogone », Lyon (1998).

In 1958, he gave lectures comprising around a hundred screenings, many of which views of monuments showing that architects have often sensed the harmony of Number Radiant ϕ without knowing the theoretical justification.

The work - which was to be called - "Beyond the Golden Number... the Radiant Number" was to analyze using layers to superimpose on the original unaltered photographs the progression, or often the various progressions ϕ , used, very close to the number Radiant ϕ .

This indeed has the approximate value $\phi = 1.325...$ and its inverse $\phi = 1/\phi = 0.755...$.

The radiant geometric progression, increasing or decreasing, is therefore very close to the progression ϕ^4 or ϕ^3 (1.333... and 0.75...).

This happy coincidence recalls that of the tempered scale - twelfth root of 2 - with some simple ratios.

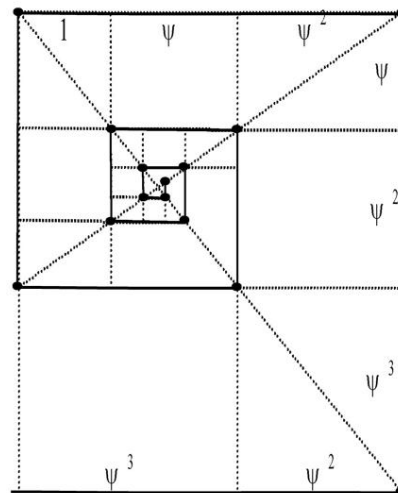

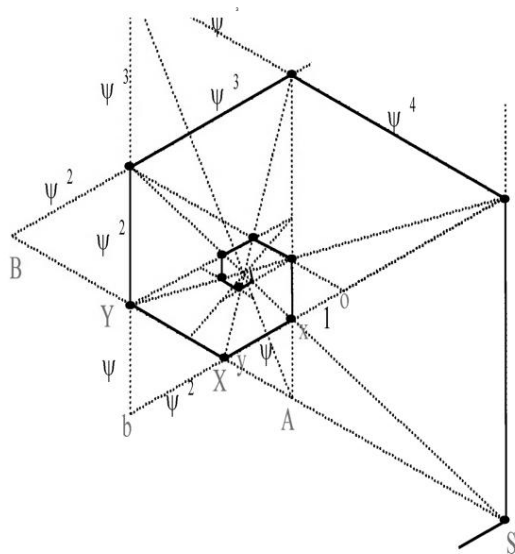

Note the approximate values of ϕ : $4/\phi$ and $7/\phi$. Moreover, a sequence analogous to that of Fibonacci - we named it after Cordonnier - is fast approaching and indefinitely by a geometric progression ϕ . We write 1, 1, 1... and each term is obtained by adding the two preceding the last.

1 1 1 2 2 3 4 5 7 9 12 16 21 28 37 49 65 114 151 200 265 351 465 616 816 1081 1432 1897 2313...

By dividing by 2 the numbers after 200, we obtain the approximate values of the powers sequences of ϕ . Before 210, up to 45, we also obtain sufficient approximations of the negative powers.

Note also the value $e = \phi^{1,151} - ...$ and $\phi / \phi^7 = 1,10$ and $(1,1)^3 = 1,331$.

One can draw for example 2 polygonal spirals, what G. Cordonnier named $\phi/60^\circ$ $\phi/50^\circ$. Exercise: Check that the right schin is detected in the center of the spirals.

Let's go back to the continuation of G. Cordonnier

11 1223457912...and let's write it again shifting 1 1 1 22 3 4 5 7 9...

Let's make the ratios according to the numbers placed on the same vertical.

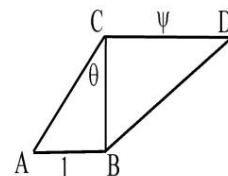

112 11 12 79 5 4 3
••••• 9 7 5 4 3 2

We get a new sequence which tends to $\sqrt{2}$.

Another 0.40° spiral derives from the study of the family of tetrahedrons

whose edges are in geometric progression. A limit tetrahedron

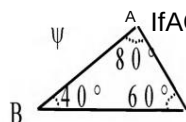

Aligned $AXYB$ defined the progression V_j . One of the tetrahedra has 3 edges successive trirectangles with progression 0.

You have to bend at 90° in BC.

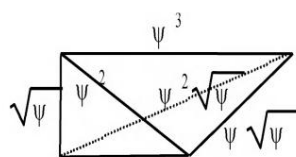

G. Cordonnier had also discovered a triangle with interesting properties: he had

called the "radiant triangle". Its sides are $1, \sqrt{2}, \sqrt{2}$.

If $AC \parallel AB, BC \parallel AB$, the angles are a few minutes of arc from those shown in the figure.

We can take these angles to draw the triangle, the approximation is completely fact correct. This triangle does not meet $|K Sh Ph|$.

Here is one of the tetrahedra of the sequence of tetrahedra which has 3 successive trirectangle edges with the progression $0 = 4/\psi$.

Remarks :

1) V_l , the Radiant number does not invert the polarized body of the tree trunk.

2) In the reports drawn from the sequence of G. Cordonnier, we find: and two terms that we

1234579 . finds in the sequence ...
 $1, 1, 1, u_1, u_2, u_3, \dots$

We see that the sequence of G. Cordonnier can be defined as follows:

$$u_1 = u_2 = u_3 = 1$$

$$u_4 = u_2 + u_1$$

$$u_5 = u_3 + u_2$$

$$u_n = u_{n-2} + u_{n-3}$$

• The sequences (v_n) such that $v_n = v_{n-2} + v_{n-3}$ form a vector space.

If (v') and (v'') are two such sequences and if $\lambda v' + \mu v'' = v$ then (v') and (v'') are

proportional:

Demonstration:

$$\begin{aligned} z_i &= \frac{v_2 v_{i+1} + v_3 v_{i+4}}{v_2 v_{i+1} + v_3 v_{i+4}} \\ v_i &= \frac{v_2 v_{i+1} + v_3 v_{i+4}}{v_2 v_{i+1} + v_3 v_{i+4}} \end{aligned}$$
 etc... So that they do not be not

proportional it suffices that: or or

A sequence (v) such that $v_n = v_{n-2} + v_{n-3}$ is perfectly determined if we know v_1, v_2, v_3 .

Soit $v = (1, 0, 0, 1, 0, 1, \dots)$ $v' = (0,$

$1, 0, 1, 1, 1, 2, \dots)$ $v'' = (0, 0, 1, 0, 1, 1, \dots)$ such sequences and $t = (t_1, t_2, t_3, t_4, \dots)$ where $t_n = t_{n-2} + t_{n-3}$

then $t = c_1 v + c_2 v' + c_3 v''$

avec $c_1 = t_1, c_2 = t_2$ et $t = (c_1, c_2, c_3, c_1 + c_2, c_2 + c_3, \dots) = t_2, c_3$

The dimension of the vector space of sequences (z_n) such that $z_n = z_{n-2} + z_{n-3}$ is therefore 3.

Exercise: We sleep the radiant triangle and a circle of radius V_l . We draw the lines as

in the figure below: We drill in the center of the circle. Show that we determine the right schin

on the axis of the circle, above the plane of the figure and the 4 components of the vital field. To verify

that the NF is imposed by the figure.

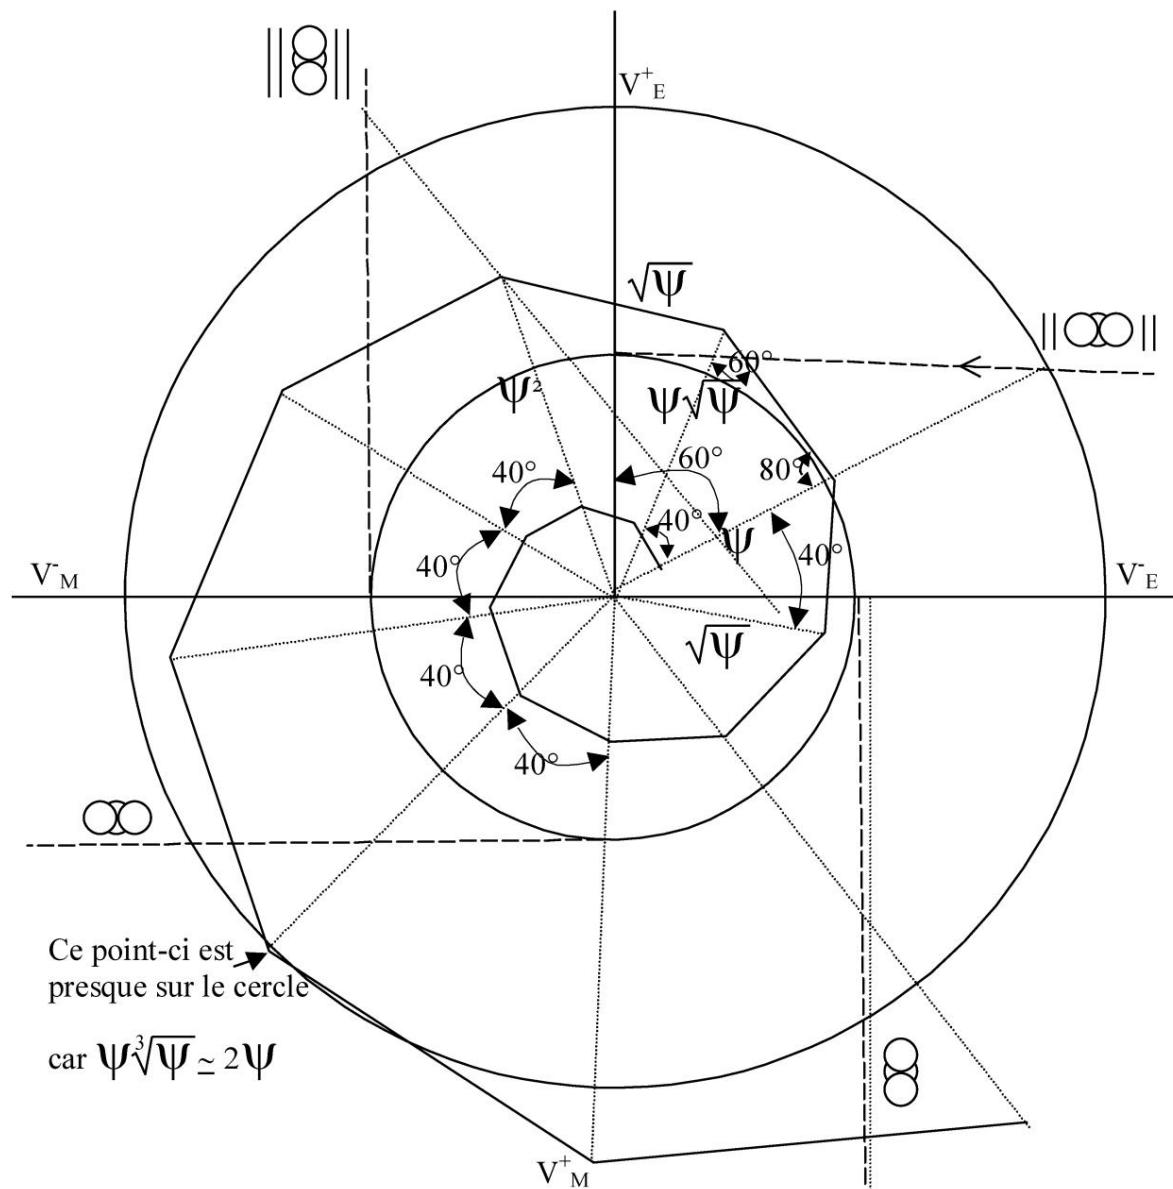

Remarks :

Give us three numbers a, b, c positive integers. Consider following $u_1 = a, u_2 = b, u_3 =$

$c, u_4 = u_2 + u_1, u_5 = u_3 + u_2, \dots$

Let's build the sequel | **So** «— ^/.

- It is possible to use vectors from the vector space of these sequences, which as we have seen, is of dimension 3. With a vector we can generate eifs.

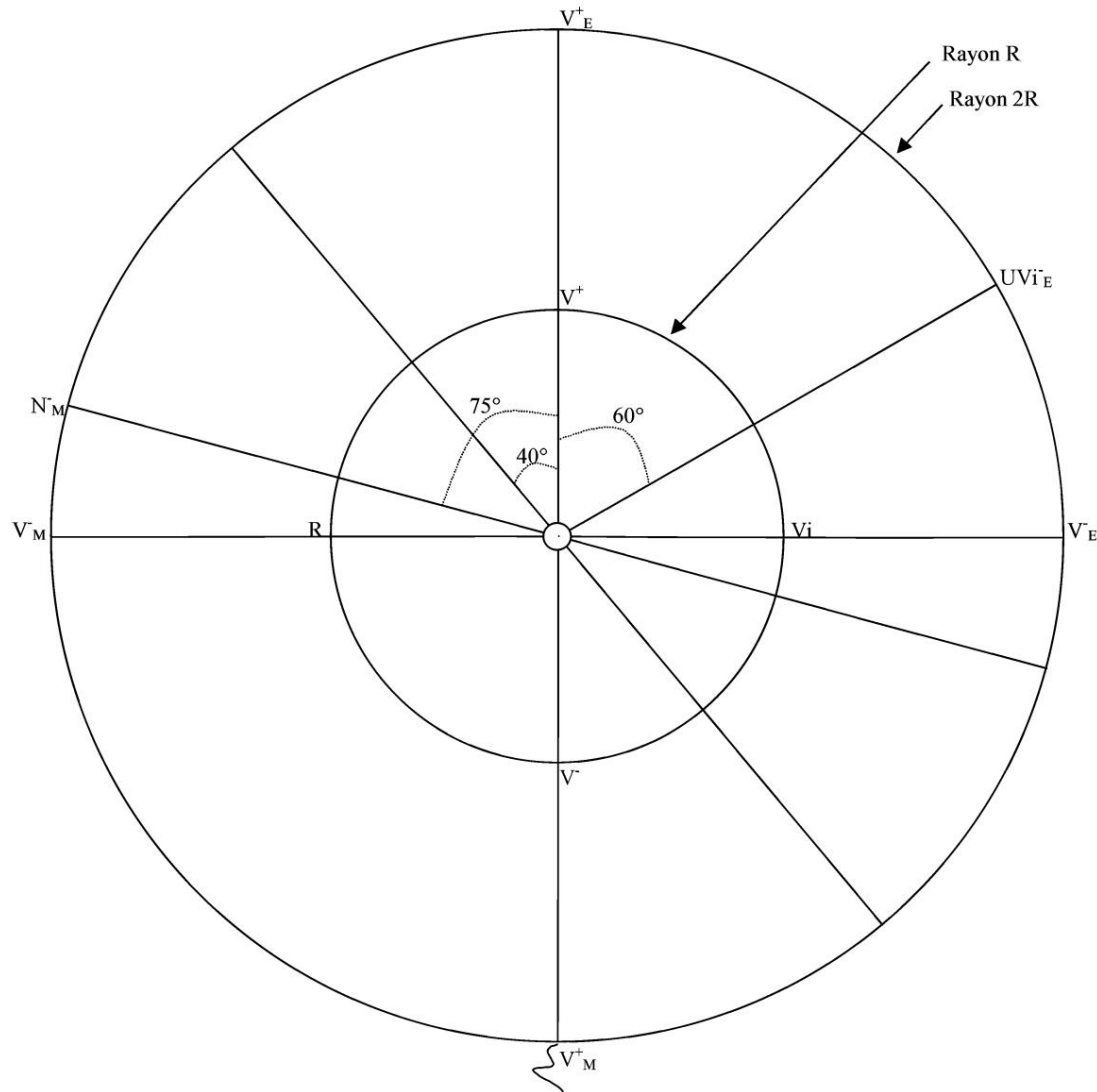

**The scientific world to which I belong
is widely
as corrupt as the political world**

Haroun Tazieff

C. Jean de la Foÿe transmitter tray

The radii and diameters plotted illustrate the physical field. The circular tray must be hole in its center right through.

With a needle of length $2R$, the differentiated spectrum is detected at $V+m$.

With a needle of length R , the undifferentiated spectrum is detected at $V+m$.

D. Square Transmitter Tray

It is interesting to produce an emitter plate of the undifferentiated and differentiated spectra which does not depart from the physical field.

This tray is a square, drilled in the center to avoid any RWCH.

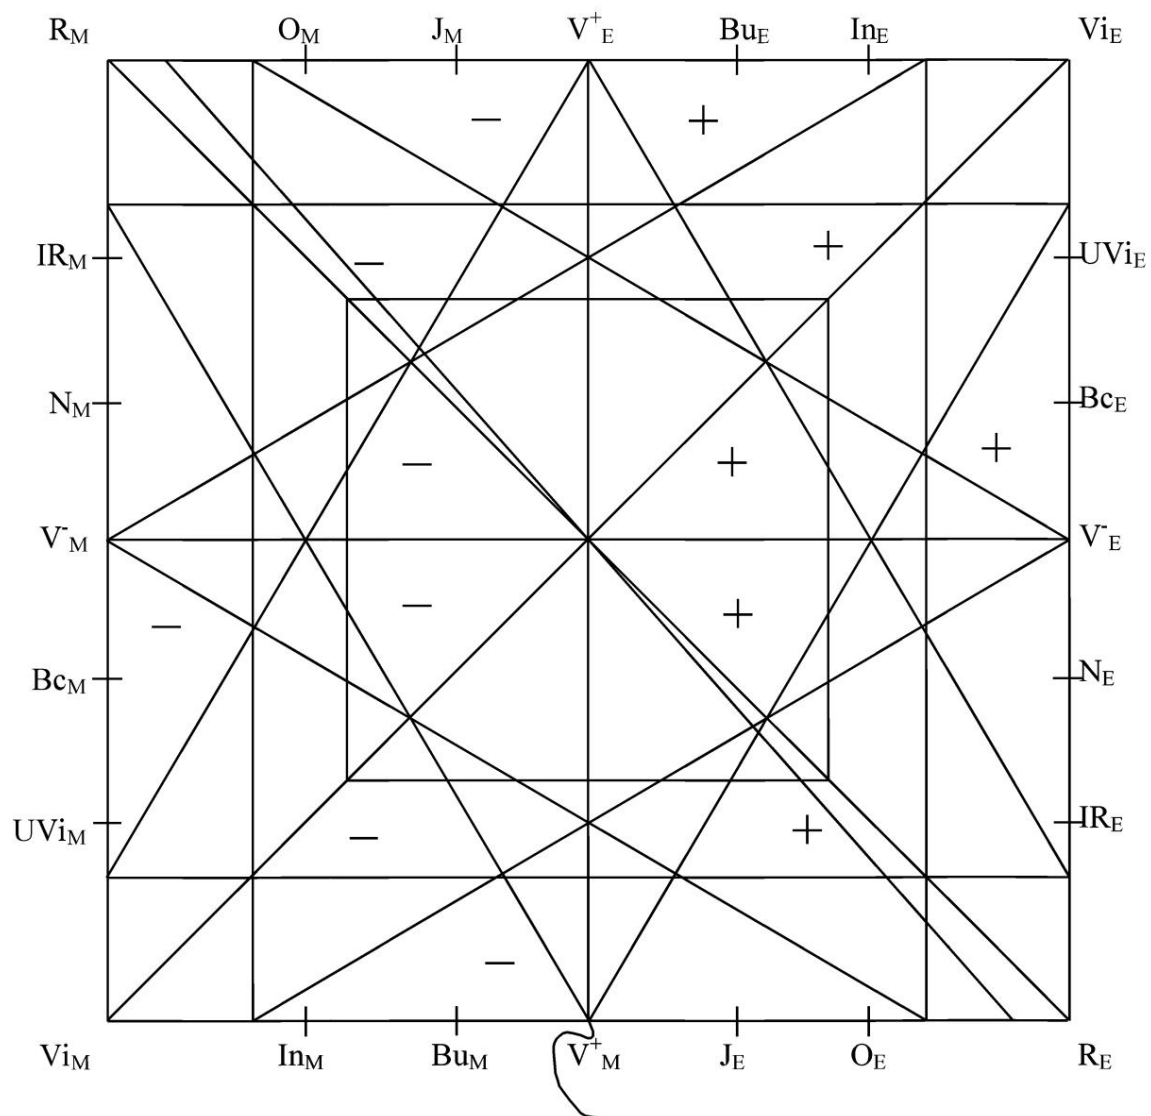

We start from 4 equilateral triangles inscribed in a square.

The differentiated spectrum will be distributed on the sides of the square, the output is still at $V+m$. We finds the polarities as soon as the square of the board has been homothetically traced, in a homothety of ratio $\sqrt{2}$ and center the center of the plate, another square which will support the spectrum undifferentiated.

The colors are no longer at equal distances.

Remarks :

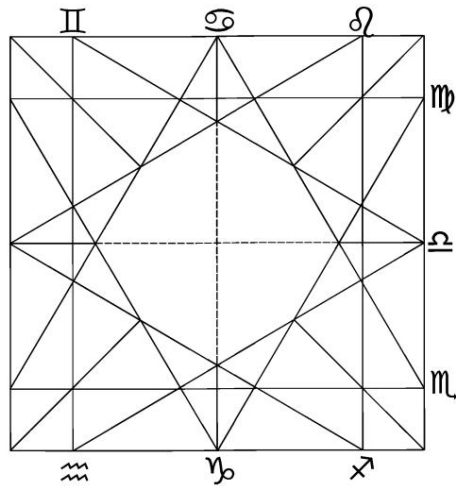

- the nature of the top material is important, wood is satisfactory. On the other hand, square tops were made of agglomerated stone; the eifs that come out change to course of time.
- The square wooden top is very stable, more stable than a circular top in the same wood.
- Some segments must be engraved but not all.

Carré émetteur

Richer² cites in a rapid study a plate with stamped reliefs found at Delphi in two fragments, one part between the treasury of the Athenians and the wall of Temenos, the other against the wall of Temenos and which is thought to have been part of the decoration of the coronation of a small votive shrine. It then supposes a complete reconstitution of the crowning of the building and perhaps even the shape of its roof with a probably octagonal top.

² Jean Richer, Delphi, Delos and Cumae, Edit. Julliard, Paris (1970)

The reconstruction of this roof following Richer is

reproduced opposite: are carried around the drawing the zodiac signs: centaur, goat, satyr, ophion, sphinx, gorgon, two lions, crab, rider, wild boar, ram, bull.

The plate found corresponds to the signs: two lions, crab, rider.

We can be inspired by this ceiling that existed or not and try to get a transmitter giving the spectrum

differentiated and even the undifferentiated, which is square to the

instead of being circular. You have to drill through the center to eliminate the level of equivalence RW CH. It is necessary to draw the diagonals, moreover it is necessary to draw four triangles equilateral arranged as in the figure. Their intersection is an octagon. You have to draw the line at 60° to the right of the line V+e, V+m, and the line at 40° to the left of this line. By tracing the homothetic square of the first square (the homothety having as its center the first square and ratio $\sqrt{2}$) we generate on the perimeter of the first square the differentiated spectrum, the colors being on radii which are 15 in 15° and the undifferentiated spectrum being on the circumference of the second square. We have the polarity + on the right of the line V+e, V+m everywhere except inside the small square and the polarity - symmetric with respect to this line. The figure in the center is a not regular convex octagon.

AND.

A few additions to the forms

It may happen that forms are not testable, they will be called untestable forms. This is the conclusion to which we arrive when we have tried the detection devices, which we check if there is no overlap, equimsey3, etc...

So we can't know anything about these forms.

Moreover, as has been pointed out several times in previous chapters, the domain of forms should get us used to getting away from the a priori of rational thought. We can therefore find forms that are both testable and untestable. These are characteristics that assembled on the same shape, make the shape completely escape us in the approach. The form may be localized or partially localized.

³ Concepts that will be considered in the 21st year course.

Let's also look at the so-called "moment-dependent" forms. We found out while working on some forms that their eifs and states were not the same if these forms were reproduced, apparently identical, in the same places but at different times.

Does this mean that they depended on the moment? No ! The word moment was chosen knowing that it depends on the context, the turn of the sentences, the atmospheres in which they are inserted. The meaning of the words is revealed in the sentence, the moment, but they impose the meaning of the sentence which means that we do not have a system with two positions in time but the sense of word which generally comes from the past finds itself being rethought, reinvested to be born in the sentence to which it gives meaning. We are in a Primer-Progenitor⁴ system.

Let's take the word moment, in all possible situations, with all the sensations that one has in thinking this word; let us project onto this multitude the concept of the moment, we have what we calls the Auréolaire⁵ of the moment. We will also name "Moment" the halo of the moment. It is in this sense that we will use the word moment in the expression "Forms which depend on the moment.

The living is always represented by forms that depend on the moment. Some forms like the Ark of the Covenant are forms that depend on the moment.

The First Temple in Jerusalem was such that some of its dimensions and the unit of measurement were thought out according to the moment. It may even be that the unit of measurement has been linked to a direction, itself found according to the moment; that's why if we do the same thing again form by thinking it, for the 3 dimensions of space with the same unit for each, by example an Egyptian cubit, it is not operative.

A form that depends on the time can be preserved but at certain times it cannot be rebuilt. The notion "same as" may depend on the moment.

In alchemy you have to take into account the moment; thus many grimoires are useless if they describe time-related operations. They only have historical value and by one way - this other way belonging to Alphysics" - we will be able to know the moment when the grimoire presented operational phases.

About the thoughts of some initiates, these thoughts could not be taken up by others people at any time; as forms, these thoughts depended on the moment. The disciple is the one who was near the Master, formed and chosen by him, and to whom

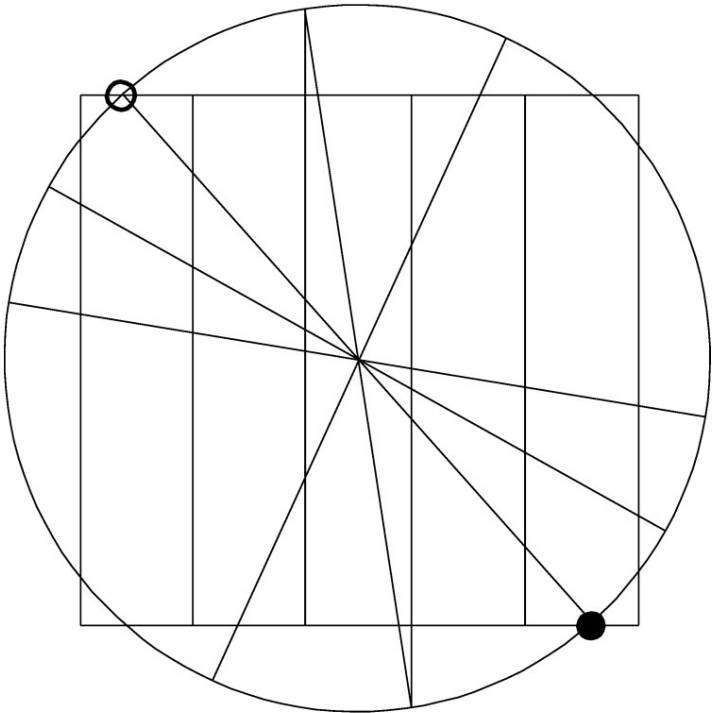

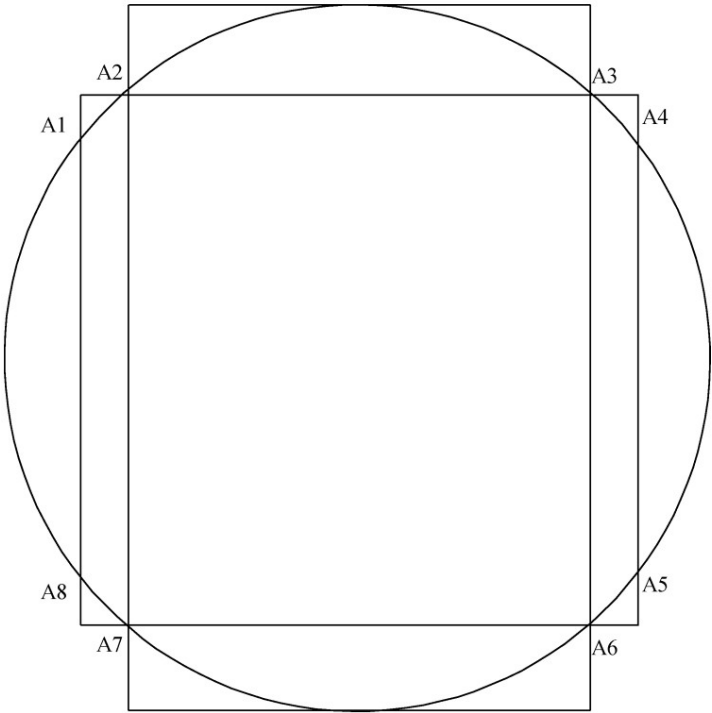

⁴ See the book by Jacques Ravatin and Anne-Marie Branca: "Theory of Forms and Fields of Coherence" (to be published) ⁵ idem

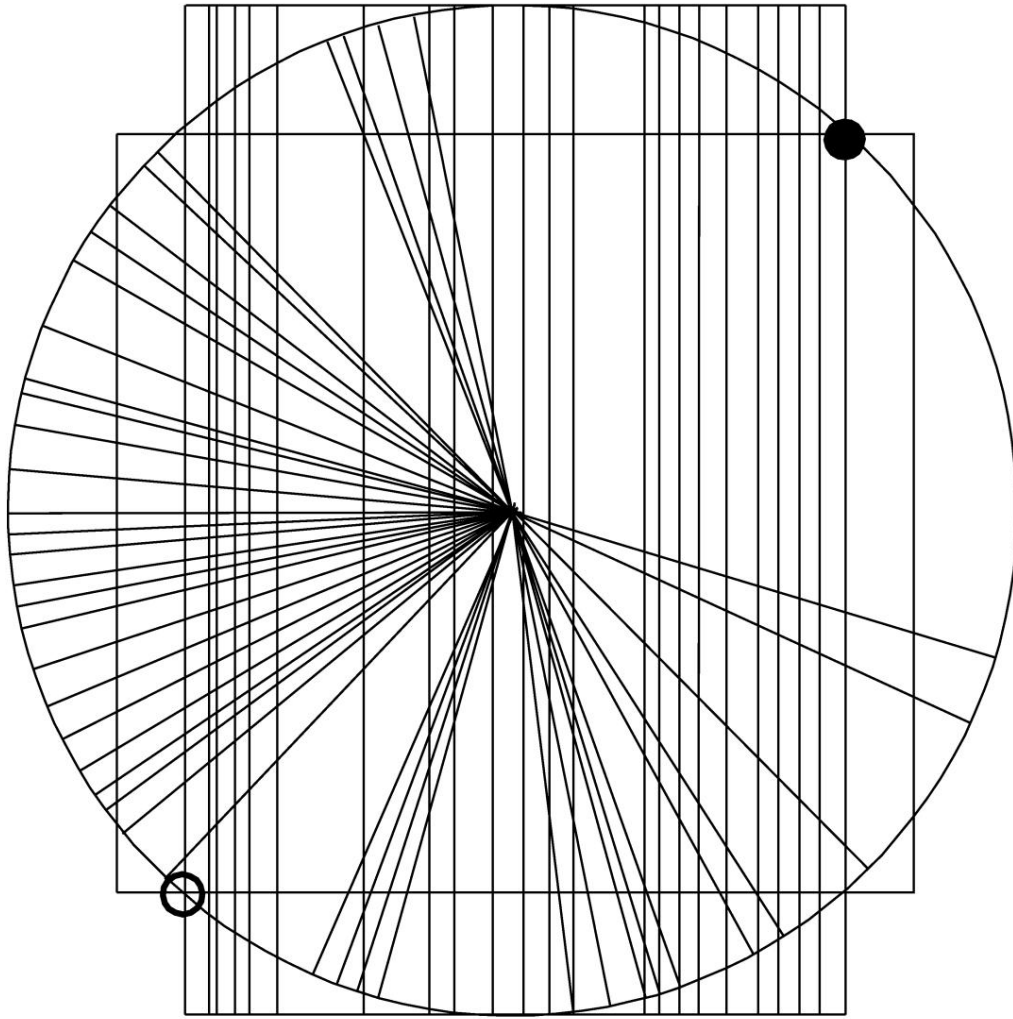

the Master gives the power to resume the teaching, at another time perhaps but in keeping everything "The substantive marrow" as Montaigne would have said.

Is a form which does not depend on the moment a degeneracy of a form which depends on the moment although feeling unconstrained by the moment gives a impression of greater freedom? We must be wary, in this domain of forms, of what we believes to win; one can, by gaining too great an adaptation, as in rational science such is the habit, losing a fundamental essence; in a sense a form depending on the moment is more an emergence than a form that could be called free - Ceci does not want say that a free form is not in certain cases as delocalized as a dependent form from the moment.

Examples of shapes that depend on momentum:

Consider a square of side length c and a circle of diameter $d = c/\sqrt{2}$ having the same center than that of the square. There are 8 points of intersection between the square and the circle. The fact of tracing these two figures in this way means that they are not located at the same level if they are think separately, that is to say when they are traced one on top of the other, if one thinks the figure total as the meeting of the circle and the square. If we do not think of the final figure as composed of two figures, they turn out that the shape is moment-dependent. She does not responds neither to RW cH nor to any K Sh Ph, but the eifs after a while do not will no longer be the same if we make the same shape and if we use this shape to rebalance from a witness, this role will disappear little by little to reappear perhaps long after and reappear again. It is not a form with variable eifs. If one wants to fix this form in such a way that it keeps the eifs, states whenever or has drawn, you must drill one of the 8 holes (this will not be the same depending on the moment) and put a protrusion at the diametrically opposite point (what will be called an anti-hole). After this operation, this form will no longer depend on the moment. Such a form can emit at C. of T. high.

Caption: Two other shapes inspired by the previous one. Holes and anti-holes are marked but they must be replaced because the reproduction process does not freeze the fixation necessary if we want these forms not to depend on the moment.

The “Kéroub” (or Cheroub) prize

by Anne-Marie BRANCA

This first year ends with this booklet. So to conclude we will present this study which apparently has a role of digression in relation to the subjects treated.

But it is necessary to place the researchers whose works.

Thus in a Pantheon, are:

Victor Schauburger, J. Keely, N. Tesla, E. Hendershott, Th. Moray, L. et M.T. Sprink, H. Morichini, L. Rota, L. Boutard, G. Lakhovsky, S. Brignand, F. Dufourg, Le Prince Skariatine, W. Reich, A. Prioré, A. Béchamp, D. Ghadiali, F. Crombette, G. Claude et J. Coutelen, G. Bergé, H. Mayer, A. Schmidt, T. Brown, Laithwait, Abbé Fortin and many more, we we haven't found them all.

They still deserved a prize, those who were voluntarily forgotten.

This is the Cheroub Prize.

Cheroub: a word made by us and which we unveiled for the first time at the Carnac congress in 1996.

Chéroub comes from 2 words: FORGOTTEN CHERcheur.

The researchers quoted above would each have deserved several Nobel Prizes, but their names do not were not even retained even admitting that they were presented. Their names are only on no stele because they had no right of expression, of even existence.

The plural of Cheroub is naturally Cheroubim - We will still write Kéroub and Kéroubim -

Thus these researchers will receive the Kéroub distinction.

A ceremony is organized by the EUREK'ALL Company for the awarding of the Prize⁷.

⁶ Congress held from June 29 to July 7, 1996, the theme of which was ... “The Study of Forms”. It was organized by Anne-Marie Branca from the EUREK'ALL Company and Bernard MENGUY from the ARKOLOGIE Association.

⁷ As for the RBB, it is also awarded a Prize: the Lebon Prize (Lebon: Nobel backwards). This Lebon Prize was imagined by Frédéric Ravatin, when he was a student engineer around 1979. This prize is reserved for a kind of individuals who are characterized as follows: sure of their abilities, eager for honor, with a cluttered brain of knowledge - "legged libraries" -, competent in certain fields, exceeding in their assessments the field or fields of knowledge, making "hasty" judgments on individuals - they work out absolute scales of classification of human beings, established according to gender criteria: the school from which the individual leaves, the ranks of entry and exit of the school, alertness, turn of mind. It's the RBB that reinstalls RBB! We have to admit that we hear far too many “researchers” claiming to be researchers, “scientists” claiming to be scientists. In fact, they are scientists, researchers

in laboratories, universities. They allow themselves in the name of their titles, even more Science - it would still be necessary that these oddballs manage to realize that Science does not belong to them, that they do not represent it, that they cannot invoke it As they wish. Fa Science, as an entity, is not on the scale of a man to speak of what they do not know, which is contrary to all scientific ethics: and moreover they allow themselves to approach domains which are not in their field of competence. - One must not take advantage of it to ridicule and reject them. There are very few real researchers, who have the soul, and very few scientists worthy of bearing this title. We are at a time when titles and denominations are distributed no matter how, become distorted, a handyman who repairs his radio claims to be an electronics technician, people with a bad cold present themselves as having the flu. - They treat themselves like having the flu, which makes the drug manufacturers happy. This attitude is an index of mediocrity in a society increasingly subject to a degeneration which manifests itself in particular in verbal formulation. - This is why it was more than necessary to create the Febon Prize.

While the Nobel Prize is discerned only fairly sparingly, the Febon Prize will be awarded quite frequently, the people worthy of receiving it being quite numerous. It may even happen that a Nobel is Febon! The reverse is, it seems, much rarer!

21st year course

“The form can be fixed, frozen;
it expresses the dynamism of the human spirit. »

Anne-Marie Branca

Cross of Saint Maur

which is located in the abbey of Saint-Maur, on the banks of the Loire, near Angers

Introduction to part 2

We saw in the 1st part of this course - 1st level of the booklets - an approach to the study of forms.

We hadn't insisted too much on the concept of form. We will now stop there more lengthily while making known a new form of thought in which these concepts will evolve.

Advice: The reader of this 21st lesson must read the whole text in order to soak up little by little this new way of thinking.

Some may claim that it is not a form of thought but an attitude of singularization of a group of researchers compared to the usual researchers. They misleading: the concepts that will be presented little by little and their arrangements do not are not at all insertable into the rational, usual thought that we will call Fields of Coherence¹ rational or usual.

Attitude and Intent

It is necessary that the reader of this course lets himself be impregnated little by little by the concepts which will be implemented during the development of the 21st level of this course.

We find ourselves as we should be.

One must have an attitude to conduct this unorthodox research; you have to keep always "impeccable" as C. Castañeda wrote. It is the attitude of the "warrior impeccable" by its rigidity, its vigilance, its open-mindedness, its possibilities of adaptation to the multiple situations found in the multiple representations, the attitude is not fixed but must be as it should be at the moment considered. We will see that the moment takes here not a particular meaning, but that it is under its true meaning, such as it should to be conceived, felt.

We must become aware that we are a form, a system of forms which depend on the moment¹ 2. The attitude does not impose the moment, nor does it impose itself in the moment, they will be bound by a process that does not take place in rational thought.

¹ C. of C. for Field of Coherence.

² We have seen in booklet 9 of the 1st level of this course the meaning to be given to this word. This word moment even in a usual sense is not perfectly determined. It is already in most cases different from the time interval.

Some might say, and in particular the rationalists, that these concepts are useless, or outdated according to the time-honored and often disparaging expression; Kant, Descartes did not quite see the relationship between man and the world as we envision it now in philosophy which seems to have leaned a little too much to scientific description of the world.

We are taking up concepts from the Ancients because we have noticed that some of these concepts had been misunderstood, distorted; they could not be assimilated by ordinary thought. That usual thought is not the only one possible; we are working to put another one in place; a new language is necessary, that is to say, the creation of terms and the assembly of these terms.

The rationalists³ will find this construction obsolete since for them there is only one understanding approach: that of rational thinking. And yet the Ancients did not think as modern man thinks. An important consequence of this remark is that the world appeared differently. Thus can be justified this thought of the Christ: "There are many mansions in my Father's house".

When we talk about attitude and moment, we think that they are linked. Their bond, which will be presented in the following booklets, is due to a tension which occurred at the level cerebral in the sensation of the two concepts, the need to create a fusion between them; so an atmosphere arises of which one is unaware; there is no more goal which would be to setting up something else, just an atmosphere; when the observer by his thought bathes in this atmosphere, he fertilizes himself and the concept springs up. As they say: the new concept is not going to be a goal, but it is the atmosphere itself. And if we wanted to justify this birth, that of the concept from the atmosphere, we would have to immerse yourself in this atmosphere that will bathe all this work, tell yourself that the expression "walking through the atmosphere to engender the concept" may not be quite accurate but that this concept and the atmosphere are already before existing in consciousness, and this in the meaning that will allow us to half-open the intention: the intention becomes the implementation of the or tension.

And in this second level of the course, this situation will be reproduced in the arrangement of concepts. There will be neither a before the comparison of concepts, nor an after this comparison. gaze; from their existence, all the consequences are. We are then faced with a kind

³ We prefer to speak of stupid and limited rationalists (R.B.); they are more and more numerous among the rationalists as a whole.

of "vertical" thinking in relation to the usual thinking which is expressed according to the scale of time and which can be considered as a "horizontal" thought, horizontal because there is flow of time.

Tensions may present themselves differently; we will say that they have 'faces'. Those faces will be considered later.

This "vertical" thought is not with the passage of time. It should not be considered two times, a "horizontal", that of physicists, and another "vertical".

Intention manifests itself in existence without landmarks.

So attitude and moment are linked by a tension face. The attitude cannot be described precisely; it will be said to be barely identifiable or not identifiable at all. We can talk about it, as one would in the rational world of a noumenon.

Similarly, the moment is not identifiable; it is not a time interval. In the moment are nested or non-nested time intervals, but if we fix a time origin for the moment, it will not be possible to define the limits exactly, whether these intervals are open or closed in the mathematical sense of the terms. Intervals will seem to leak and their definition fade away. The concept of interval becomes unstable. The noumenon is also not identifiable, not expressible by rational thought.

One can, on the other hand, envisage a passage from the phenomenon to the noumenon, which will call for a way and we will write: . Naturally this way has existence only by the concepts of departure and of arrival. By permuting them, we would have the opposite route which we will write as route $\bar{y}$ l.

The concepts that we will put in place little by little and the paths between these concepts will be transported to other concepts like schemes. Multiple lanes can be placed following geometric figures, such as star pentagons or other flat shapes.

Such figures and the ways will constitute new entities which will be able to associate.

Ways and concepts can be exchanged in the schemes.

4 In Kant's philosophy, the noumenon is the "thing in itself", such as it exists, independently of any being capable of knowing or feeling it. The noumenon is opposed to the phenomenon which is the thing as it appears to our mind; experience only lets us know the phenomenon, and the noumenon escapes all experimental knowledge; the fundamental problem of philosophy is, according to Kant, precisely whether the human mind can, by reason, reach the noumenon [i].

Here too, phenomenon and noumenon, in rational thought, are not always identifiable, at least for the first, as for the second, it is never identifiable. The phenomenon is the thing as it appears to our mind; our mind can set benchmarks, say to which set the phenomenon belongs if that is possible, and the notion of belonging is already a location. To speak of a "thing in itself" is the negation of all reference points, whether in ordinary space or in an abstract space as we define it in mathematics.

The brain uses these patterns; they do not develop over time; they are already before any awareness of their existence.

You have to bet on what you find; the attitude contains that. We must understand, and this is difficult for the rationalist researcher to recognize that the observer, if he is a real researcher, knows⁵. Of course, it is not necessary to separate by a time scale the fact of knowing and that of being; both, knowing and being, are presented in tension⁶. This is another face than that of the tension between attitude and moment. We'll never have to deal with tension but to his faces, from which is elaborated a sheaf of paths that will go from these faces to the intention. Thus we will have multiple ways, paths. All are possible, used.

Then from each path may spring another sheaf; everything will build like fireworks and this right now.

We can say that awareness (which is in time) emerges from this instantaneous. The tension also appears thanks to this image: the human brain behaves like glaciers on rocks; they forge them. When a brain in the society is hampered by this society, it is pushed, deformed, and something else comes out of it.

So there is tension between a brain and society. But how can we envisage society, abstract concept? The society we are talking about here is the one representing the rational world. Society and world are thus two poorly localized concepts. Society is the set of humans from industrialized countries, these humans united by nature and laws, customs; the rational world is the whole of the individuals of these industrialized countries but with in more the laws, relationships between individuals; you can still put multiple characters in the expressions today's world, rational society.

⁵ An anecdote linked to Albert Einstein shows that he knew his hypothesis true long before it was verified [ii]. There were two major expeditions organized in February 1919 to observe a total solar eclipse, to Sobral, in northern Brazil, and to the island of Principe, in the Gulf of Guinea. They both demonstrated that Einstein's calculations were correct and that it was therefore necessary to abandon the conception of the world that had been imposed since Newton.

Dina Marianoff reports this: "One of Einstein's colleagues from the University of Berlin was there by chance when the photographs of the eclipse were in the hands of the researcher. D said to him, "You must be happy, you have the proof of your theory in your hands." "A proof?... a proof? repeated Einstein with that surprised, questioning air that always gives the impression that he is only a visitor on earth. "A proof? They are the ones who needed it! I wasn't looking for it! "".

Let us also quote this other anecdote of Antonina Valentin relating the memories of Elsa Einstein: Einstein looked at the photographs (they gave the proofs of General Relativity) with a surprise which changed into a joy illuminating his features "It's wonderful, it's truly wonderful! ".

It was entirely believed to be his triumph. When the importance of this confirmation was explained to Mrs. Einstein, she ventured, shy: "How happy you must be, Albert! ". And, Einstein, his eyes still riveted on the photograph, replied: "I am delighted! ". But he immediately added: "I would never have believed that photographs could reach such perfection." So he was talking about the quality of the shots.

⁶ In the case of rational vision this is not generally apparent.

In these cases they will be assimilable by rational thought, used in this thought⁷ ; they will in a certain sense be identifiable because describable by elements belonging to the language usual. Although the notions of a rational society, of a rational world are not defined with precision⁸, they enter into everyday thought. These notions, while not quite identifiable can immediately be associated with their container, which is perfectly identifiable⁹. We thus confuse them with their container as we confuse the forest with its container which is the set of trees sufficiently close together, sufficiently bushy and deciduous, in sufficient number. But we will see later that the concept of forest has something moreover which means that it does not belong to the usual thought.

The tension between the brain and society can be seen as caused by one of the faces of intention, this intention which will be presented later, the importance of which is fundamental.

You have to bet on what you find, discover: the attitude contains that. The bet is not taken here in the sense of the word intervening in the game, but in the sense of the one who wants to know for hear and not to win and dominate others, or perhaps win for him if he fixed a goal, although he must forget the goal to devote himself only to the path.

It must be understood, this is difficult for the rationalist to assimilate, that the obs, if it is a real researcher, knows (refer to footnote 5 of page 1, note linked to Albert Einstein).

Naturally we must not separate by a time scale the fact of knowing and that of being.

Both, knowing and being, present themselves with such intensity¹⁰ that they are in tension.

Carlos Castañeda talks a lot about intention[iii]. It is for him the spirit, what is before abstract, "the dominating force of the Universe ... the force which modifies things, or keep them as they are". The intention changes the state of the obs or if we consider this "vertical thought", intention and state are in tension. In the intention there is more than the

⁷ rational or usual.

⁸ a concept emerges little by little in the mind of the child, settles there without definition and he will be able, as an adult, all his life to use it without further knowledge, and quite appropriately.

⁹ We can thus introduce the non-locatable notion (known as delocalized), of the enel of a society. It should be noted that concepts related to the non-locatable are used in everyday thought; this is because the human brain does not naturally construct a rational world; moreover, ordinary thought has become very powerful, and it absorbs all the concepts of the rationalists better and better, more and more in order to stabilize itself, because even in ordinary thought, areas of instability appear, fractures which must be resolved. to fill in.

We will not say that everything that is identifiable constitutes rational thought but that everything that enters into this thought will one day be able to enter into a rational context and then the non-identifiable character disappears to serve absolutely rational results. We could say that rational thought - the rational field of coherence - sets up terms, concepts which by a certain tincture are elements of this field of coherence.

¹⁰ About the rational vision it is perhaps not possible like this.

to want, there is the will in becoming; but wanting to become is also in the moment, it does not does not spread over a time interval.

The other is no longer potential, it is¹¹ : it is a present of extraordinary richness. All that we will see later, how “the network of the future” is fertilized by this present; this present overflows itself to exist in this network. The present is diluted in the moment which, itself, is partly relocated; the moment placed in this moment, becomes an emergence; the moment is otherwise reimagined; from a time interval element it becomes a memory of a location.

Castañeda writes again “The intention creates buildings in front of us and invites us to enter them. This is how wizards understand what is going on around them. Wizards then talk about symbols. The symbols are the return to the present usually understood investments of intention.

The intention imposes representations. Some are easy to set up, that's what can occur for example with the placebo effect, well known to everyone where effects are noticed, attributed to other so-called psychological effects. In the case of the placebo effect, everything it contains is put in place by the one or those who make the experience a representation: the remedy that will be given to the patient is supposed to contain the drugs that fight evil. The patient will enter the game but he is deceived: the caregivers want distort a story. This therefore corresponds to another story that is taking place, which we will call a path. The patient's trust in those who care for him is part of his intention, so is his desire to heal. Likewise the intentions of the doctor, nurses who participated in the experiment intervene^{11 12}.

This explanation presented here is not the only possible one. She is also slightly incomplete ; it will be presented later in the course thanks to the implementation of concepts new. Then we will also find cases where several explanations are possible. simultaneously. Each explanation is attached to a path, a path. We can thus have several possibilities, what we will call a sheaf of possibilities. In this sheaf, all channels will be used; tensions may appear between the paths of a

11 Here we are faced with a “face” of thought: “I am he who is”. Awareness of this thought comes afterwards.

12 If we test the water that is supposed to contain the drug according to the methods described in [4], we find in this water characteristics that it did not possess before the establishment of the intention of the caregivers. The intention of the patient takes up these new characteristics of the water to amplify them, multiply them, stabilize them and his condition will go on improving, the product by the intention being supposed to treat the patient. It is a face of this intention that comes into tension with the intention of the caregivers and the new characteristics of water. There is no more cause and effect when tensions arise. The water, for example pure at the start, is impregnated as in the case of a homeopathic dilution.

sheaf or between a sheaf of one case with a sheaf of another case. So everything swells, develops, but not in a time-indexed evolution, in an instantaneous of existence. The intention can be associated in certain circumstances with a neighborhood. Thereby if we choose a plant that can heal; what we are going to treat will depend on a neighborhood which is not that of the plant but of the one who intends, and the neighborhood of the one who has intention can become neighborhood of intention.

On the subject of the moment, it is necessary to know how to identify the moments, for example "to die not when we want but when we have to [iii] (volume 8)".

The "implacability" of the nagual [iii] presents itself in several facets. She is like a tool that adapts to several uses. The functionalities of the tool are diversified and it allow for various uses.

The tool thus has multifunctionalities, multifunctionalities associated with an object technique or adaptation of the tool to other technical objects.

Implacability is an attitude. The attitude characterizes a level of intention related to the nagual [iii] (volume 8).

Castañeda emphasizes intention through the eyes. We are faced with the power of the gaze. Being human can convey its intention through the eyes, but it is far from being the whole intention. The eyes¹³ are both the reflection and the sparkle¹⁴ of stories happening quite elsewhere. They allow to transport in the usual thought (field of usual or rational coherence¹⁵) sensations belonging to the other thought (another C. of C.). Between reflection and sparkle of the eyes there is tension¹⁶.

Let's continue with the notion of intention. Carlos Castañeda used it in [iii] (volume 8). It's necessary notice that Don Juan, the Yaqui sorcerer who initiates him, does not have the adequate language for this that he wants to make Castañeda feel, but he had a remarkable training; so he can transmit through gestures, periphrases, examples mentioned or experiences carried out in the field. Don Juan is like the ancient sorcerers he speaks of "He is not focused on thought, he leans towards action"; on the other hand compared to the old wizards, there is in him a attempt to put an understanding in place. It does not achieve coherence but it transmits. Let's see what he says about intent:

³ seen in ordinary thought. But the eyes are not comparable to a system of lenses.

¹⁴ reflection and radiance: concepts developed and used by Goethe.

¹⁵ Field of Coherence: abbreviation: C. de C..

¹⁶ This tension is an "equimsey", which will be explained later.

« ... there exists in the universe an immeasurable, indescribable force, which sorcerers call intention, and that absolutely everything that exists in the entire cosmos is related to the intention by a communication link ... » « ... sorcerers drew knowledge directly from the intention, without the awkward intervention of spoken language" (this is naturally from the spoken language of the usual C. de C.). "Intention is the universal force¹⁷ which makes us perceive". We do not become conscious because we perceive, in fact, we perceive because of the pressure and the intention of the intention. It is the intention that is put in tension with itself.

A healer from Berry said during a television program "It is the Intention that makes succeed when you want to cure a sick person".

He perhaps did not foresee the deep meaning of it being too implied by this intention used in everyday language which expresses a will in an action to be carried out and this, in a establishment.

The intention as Don Juan feels it, and presented by Castañeda, seems to express itself thus: it precedes thought and is found in thought. It is both a primer and a progenitor [iv] and [v]. It can be said that the intention sinks deeper and deeper of his own intention [v]. All of this, later, will be expressed in an adequate language¹⁸ [vi].

¹⁷ Don Juan uses the word strength because he uses everyday language to convey a message.

¹⁸ Primer and progenitor will be developed later.

"True scientists are poets and imaginative.

Without them, Science would not exist.

The others are accountants and grocers,

they don't find out.

And besides, that life would be boring without imagination..."

Paul-Emile Victor

Reminder: A lot of isolated researchers, remaining isolated all their lives and unknown to everyone, their documents, diary, notes, ending up in attics when they die and then being thrown away during family moves, were drawn to the eifs and gave little approaches similar, at least when it comes to classifying them. It comes, as it was previously mentioned, of the representation that the researcher was asleep as well as of his tacit knowledge. Some (and this is true for the most part) have not even bothered with the notion of state, which we will see later, which led them to a simplistic classification (but sometimes useful) of what they called the "good waves" and the "bad waves", or the "fluids beneficial" and "evil fluids" ¹⁹.

Enel (Prince Skariatine) had, after his return from Egypt, around 1923, given a classification; to do this he had created a correspondence between the visible part of the spectrum electromagnetic, to which he added infrared and ultraviolet, and eifs. For him, this was not confused, but essentially linked to colors ²⁰. He could have chosen a whole other scale. He himself also classified them as acidic and basic; so we find:

Red (R)	Blue (Bu)
Orange (O)	Indigo (I)
Yellow (Y) <i>*so-called positive or acid colors</i>	Violet (Vi) <i>>so-called negative ²¹ or basic colors</i>
Infrared (IR)	Ultraviolet (UV)
Black (N)	Blanc (Bc)

He found a correspondence between the "colors", the various elements of nature and organs of the human body. He used this correspondence to heal and he had results spectacular. He summarized this in his works, we will not develop them further.

On the other hand, these correspondences are interesting because they bring together the fact that from when we are looking for a correspondence, in an unexpressed way, we place in "look" two sets, and the ordered set of emissions (because we can place them on a circle or on a straight line), in this delocalized domain of the eifs, placed on that of the organs by example, entails an operativity on the elements of all the organs.

Enel could have chosen another scale, for example, electrical voltages, intensities of electric or magnetic fields... and on certain divisions of the dial say: I have a

19 This denomination of "good waves" and "bad waves" nevertheless makes it possible to test a place and even to rebalance it. It is a very simplistic description but the dowser can make a representation for himself. It will simply be difficult to transmit. Moreover, it will not adapt to the use of eifs for industrial purposes, for example.

20 Enel had realized that the "emissions" were not electromagnetic waves, while some who followed him did not have his lucidity.

21 Colonel de Rochas seems to have discovered 2 of them, one blue and one red, but he is not sure that they were eifs.

emission every 15 volts, every 5 amps, every 10 gauss ... Bovis and Simonetton have moreover built devices supposedly measuring the wavelength of the human being in angstroms (for example 8500 Å for an individual will mean such a thing: he will be approximately in good health). We will talk again about these arbitrary scales imposed in the field of eifs more far.

We did not mention green in the list given by Enel; he noticed that there were of them ; one was named positive and the other ^Unegative. It is this negative green (actually V'e) that mummifies meat, fish, it stops decomposition and kills all microbial life. We found in the great pyramid of Cheops, likewise it is emitted by the statues of the Isle of Easter.

Note that Jean de la Foÿe [vii] used discrete spectra but also lines of spectra color continuums. On the other hand, Enel only used the discrete spectrum but it had to have awareness of the continuous spectrum. It should be noted that people using a discrete spectrum and that others using a continuous spectrum may not give the same results after study of forms^{22 23} ; each of them will however be right; it all depends on the performance. There will have no function related to a probability to indicate results obtained from the discrete spectrum and reported on the continuous spectrum. Moreover, other researchers, just as isolated, arrived at completely different classifications which gave them consequences valid both in medicine and in the detection and rebalancing of harmful places and dwellings.

Depending on what the obs puts as concepts in its model, it recovers phenomena: so it is with the od, the auras, the Kirlian effect, the orgone. Then all this goes into knowledge on the scale of a people or even planetary; you have to be careful that this passage does not distort the phenomena. But let's not forget, depending on what the obs puts as a concept in his model, he recuperates one or more phenomena.

22 R. de Lafforest often talks about it in his works. Bélizal, Chaumery, Morel have studied it although the description of the discrete and continuous undifferentiated spectrum belongs to Enel. We will thus have the eifs of the EFF level of the discrete or continuous undifferentiated spectrum or of the differentiated or continuous discrete spectrum of types E and M. We can moreover not consider the continuous spectrum as a complement of the discrete spectrum - This is a point view acceptable, it all depends on the representation -.

²³ Jacques La Maya [viii] also adopted a simplified classification using the denominations "waves good", "bad waves".

24 The eifs and we will see later, the yews, the avaecum, the wyverns, the arkhams, the mahkras... correspond: to a more or less advanced delocalization of the form or of the system of forms but also to the fact that the obs is in front of the form and that he has considered it as being in the ET (usual point of view) or partially inside, and also to the following fact: the obs, while knowing he is an origin, flattens his vision, that is to say considers what surrounds him existing outside of him. This position of the obs is found in the usual C. of C., but the fact of having become aware of it places it in a trace of the other C. of C. in the usual C. of C.. It is a bit like a shadow of the other C. de C. on the usual C. de C.. The second C. de C. accepts

The form

The concept of form is presented differently according to the times. And here, the eras, they themselves are not envisaged according to the usual view. They are not perfectly defined. We won't talk about it like in art, literature, from the 17th century, 18th century century, etc.

The times will not be perfectly defined. They are like the moments - see the Fascicle 9 of the 1st level - their edges are leaking.

But when we think about this concept of form, we try to embrace - and not impose as it is done in rational thought - the thought of people who belonged to those epochs.

In the usual C. de C. the form is immersed in the space-time structure²⁵. ET is given a priori, in first truth, the forms come later.

We don't think of forms that way. For us the form emerges or immerses itself in the AND structure. It is as fundamental as this structure.

The form thus becomes fundamental; it is both a landmark (we rely on it to consider its entourage, which it is not) and difficult to identify (if it is not quite present in the AND structure). It may not be completely localized, i.e. not completely present in the ET, i.e. still not completely describable in this structure.

But in addition the form is the "Way", which will avoid speaking of the form and of what is not the shape. At the same time as setting up the model, the representation(s), it is necessary follow the spirit as it goes. The mind conceives the form and then contemplates it. He's more correct to say that these two actions are only one. As picture, we can lean on geometrical optics for which object and image are linked but in addition, here, object and image would be one; thus one can consider the model as the object and the way as the image.

From the way one derives the necessary discipline of mind when one leaves the usual C. de C. - discipline that does not express itself; it is implicitly included in the way - so as not to

this position as soon as the obs became aware of it. It's not an excess of language or an extension, it becomes an operativity. This is all the more valid since one cannot arbitrarily think of a human being as an origin (that is to say, launching his C. de C. in which he finds himself as well as everything that exists). Now this can only be lived by the obs and then there is only one obs. But human thought seems forced to choose, in order to define itself, to hold this position in which the obs launches its C. de C., despite knowing it, it cannot use it in this way. And this impossibility of use is the "thinking sheet", the noosphere of Teilhard de Chardin [ix]. Thus a blockage on a human scale is creative and operative for the human species.

²⁵ Space-time: ET.

fall into phantasmagoria, the latter not always belonging to the domain of the absurd although often they belong to it.

According to [i], it is the state under which we perceive something; the concept is likely to assume all sorts of shapes and forms. The notion of state appears here, but when we will speak in the following fascicles of the state of a form, we will not retain this definition.

When we speak of "geometric shape" it is about the external configuration of a surface, of a volume or else in the case of a curve, it is the aspect of the curve but

the appearance without sensation.

We must, when considering forms, take into account the interior as well, the composition, matter. We will therefore have to think about form and material.

The word form is used in metaphysics in very different senses which vary according to the authors, as opposed to substance, essence, matter. In general the philosophers designate under the name of form the ideal principle of beings in opposition to the matter, which represents the underlying chaos that is organized by the formal idea²⁶ [i].

Note that the word essence does not correspond to a locatable, localized notion. He is linked globally.

We also call forms the ritual words that accompany a sacrament: it is which is usually expressed by "the form of a sacrament". This latter meaning, considered in [i], is important for what we develop. This form, as we shall call it, is in largely relocated. G. Simondon [x] writes: "the notion of Form, in all doctrines where it appears, plays a constant functional role: that of a structural germ possessing a certain directing and organizing power; it supposes a basic duality between two types of reality, the reality which receives the form and that which is the form or conceals the form; ... the form is consistent with itself. The notions of the archetypal form of the Platonic or hylomorphic genre.

G. Simondon introduces coherence [x]. The psychology of Form developed in psychology of expression considers as primitive reality the meaning, in fact "the meaning is given by the coherence of two orders of reality, that of individuation and that of individualization" following the thought of G. Simondon.

²⁶ This point of view will not be considered.

²⁷ **Hylemorphic** : is said of an individual generated by the meeting of a form and a material and the other point of view: Substantialist : being consists of its unity, it is given in itself, it resists which is not itself.

Both points of view, points out G. Simondon [x], "assume that there is a principle of individuation prior to individuation capable of explaining it, producing it, driving it".

Individuation is the set of particular qualities that constitute the individual and the distinguished from another. This individuation is elaborated from a principle.

Principle of individuation : among the scholastics²⁸, what gives concrete existence to a being and individual.

Let us point out the term individualization which is different from individuation.

Individualization is the action of individualizing but also the effect of this action and again the state of the individualized object. In [x] we find the following example: the individualization of the penalty for the same offence, i.e. the application of different penalties to the perpetrator or perpetrators and accomplices, taking into account the individual elements specific to each of them²⁹.

We can say that individualization comes after individuation. We consider actions according to what has been brought into judgment on individuals.

For Gilbert Simondon the meaning is given by coherence - a fundamental notion in this course - of two orders of reality: that of individuation and that of individualization. Coherence - this word seems well chosen here - is placed as a checkerboard on which shapes and events move and are ordered. Consistency presents in this context as a superdans³⁰.

In this course the word coherence, thereafter, and in the expression "field of coherence" is not a consequence but a first truth.

We thus note that the compatibility of the two orders of reality, individuation and individualization, is expressed by what underlies the whole: coherence.

We can consider the point of view according to which we have two faces of coherence such that one underlies individuation and the other individualization; the incompatibility of a face with the other causes a collapse and a new face of coherence emerges.

The collapse is experienced as an implosion that would generate a creative world.

Coherence can be considered as a monad. In the monad, we speak of principle and source³¹. Often principle and source are not expressed, and everywhere we speak of

²⁸ **Scholasticism** : what is taught according to the ordinary method of the Schools of the Middle Ages. Pejoratively, that which deals only with form and which remains distant from what attaches to observation and life. In Europe, Scholasticism was taught between the **12th** and **17th** centuries. She seeks an agreement between reason and revelation [i]•

²⁹ **To individualize** means to consider individually, to separate, to abstract from the species.

³⁰ This will be developed later in the course.

³¹ **Monad** : Leibnitz's definition alone is retained; the monad presents itself as a simple and irreducible "force", which contains within itself the principle and the source of all its actions. That is to say, the monad contains what it is. Let us then consider what will be two faces of the monad: one the principle and the other the

monad, for example Louis Boutard's aether monad [iv] and [v]. This researcher does not have explained principle and source because he did not know the thought developed here called "thought arkalienne »³² ³³.

From concepts put in place, we can generate what seems fundamental like the consistency. We will no longer necessarily set up, as in the usual C. de C., one or several basic elements and a construction from these elements. We will be many more faced with a system existing in itself, sometimes even a monad containing one or more several monads.

We see that this construction is not a descriptive rational approach; the constructions that will follow based on concepts such as equimsey, dynamic duality, overlapping, will put in place elements and other notions that will form monads or something else.

According to G. Simondon [x] the form is defined as the state towards which the system tends when it is in balance. This equilibrium may be stable or metastable. "What makes the good form is not that of the geometric description but that which establishes a transductive order to within a system of realities comprising potentials. This good form retains its potentials by compatibilizing them; it is the structure of compatibility and viability".

The form becomes a generally metastable system to individuate itself. The form emerging or immersing itself, as we envision it, is not totally incompatible with this point of view.

view.³³

The form can be considered as a metastable system in these emergence and immersion. Thus we see that the formulation of form in emergence or in immersion allows to build two ways:

· the form's system-en-Voisl)it
individuates metastable state J

1-way metastable system II >
emergence or immersion form J

source. There is a tension between the two faces. Moreover, principle and source are linked in another way. Later in this course we will express it by what we call a "forlia".

³² Arkalien, arkalienne: comes from the name ARK'ALL created by Jacques Ravatin in 1980. ARK'ALL is the name given to a research group which is the offshoot of the TOTARIS association. The latter has been replaced by the DECALUM association which proposes the Study of Material and Intellectual Systems escaping the usual logic.

³³ According to G. Simondon, the notion of form can be replaced by that of information. We will not follow this path because information is an intuitively rich notion but which loses a lot in its formulation which is linked to Shannon's definition and thus to entropy. Entropy only makes sense for localized systems.

But tensions can be set up between path I and path IL. By watching oneself think, we can follow again the cerebral processes that we use and make appear new ways.

The concept of path has many faces. It is thought out abstractly and we tend towards multiplicity of the way, a face. Or of an element of multiplicity, using the concept of face, we establish the abstract concept of path. This constitutes two more faces of the path. These seem new because they have been elaborated after the fact; they are in the process cerebral which, when it expresses itself, puts in place much more than it seems to have made. The system put in place is both a starter and a parent of itself.

The monad is also primer and progenitor; that is to say a system that we will designate as "AG system" ³⁴.

In AG systems there may be one or more voltages between A and G. This will be considered later.

Let us consider a concept in the usual C. of C.. This concept makes sense in a certain area du C. de C. But one can, for literary effects, use it in other domains, analogies arise, analogies of situation, construction of sentences, puns, effects of sounds. Thus this passage from a domain for a word to another domain will constitute a way. We will say that we have carried out a "structure transport". This way that we have to our disposal, we will use it in a more general way by making transport of structure on the track. We are thus going to pass from a domain of the usual C. of C. to a domain of the other C. of C.

The other C. of C. is hardly accessible to us, also by this process of a domain like the one to which we are associated by the word, we pass thanks to this new way to another domain ; this other domain is not generally known and the process will still extend because the transport of the word will cause the setting up in the other C. of C., of a domain at the subject of which we know almost nothing or even which is completely unknown to us.

G. Simondon speaks of Field of Form "the form which contains within it a certain field"; and he calls this form "good form". This field of form is the fact "... both of a isolation between two terms, antithetical, contradictory, and yet interrelated...". This field must be able, still according to G. Simondon, to produce energetic effects if one introduce something. He recalls Plato who wants a form to follow a dyad or a "plurality of dyads coordinated together". There is both unity and multiplicity

³⁴ The AG type system will be presented later.

"One and multiple, signifying connection of the one and the multiple, this would be the structure of form ".

We note that the assimilation of a form, as it presents itself in thought Arkalian, is only done in stages, not necessarily attached to functionalities since the most of the forms we envision are largely delocalized; this does not happen not present as a transduction which is a process where one relies on the last step to build the next one; we are faced with emergences that are being put in place by unity, that is, what will be the form in the process of partially emerging or even not never emerge enough to be described with our five senses; in this last case one can test such a form, very correctly; we only know its properties. The properties gradually become form; other properties are beyond suspicion; they may become perceptible to the obs when it comes to setting up new concepts. These concepts are in the emergence of the construction of the form, they do not come not after although they show up after. The form under construction carries flight into his existence; it is this flight which makes all its richness and which expresses its unity, because unity is not only the establishment of coherence between concepts - in find the coherence that we went to draw to build the C. de C. at the beginning the form is -, both stabilizing and creative.

Forms can be testable, intestable (some, but rarely respond to both qualifiers if we agree to leave the usual domain). They can also be overlapped, in equimsey - or even simultaneously can occur overlapping and equimsey, also in dynamic duality - and all the above can be combined -; still present the open, decal-like shapes, shapes that depend on the moment, not localizable, crossed out, with variable eifs, the forms linked to the aether. The list is not exhaustive.

Let's come back to the so-called "moment-dependent" forms. By working with certain forms we realized that what we could detect on them, what was linked to them, was not stable over time³⁵. This may be due to special states³⁶. But it's not always the case and it was necessary to become aware of the forms produced at a certain moment, and not at a time ; the expression here is very important: "at a certain time" entails a time interval and this in a certain place, therefore leads to the conception of a neighborhood in the fairly well delimited ET, moreover fairly well localized since it is in the ET. So

³⁵ J. Ravatin

³⁶ J. de la Foye

that the moment will suggest a flight of reference points at the limits of the time interval (one does not will no longer be able to speak of linear unfolding of time, simply in the moment there is localized, like an anchor point, even in space).

The moment is linked to the context, to atmospheres; to intentions; let's project the word moment as we have considered it on the background constituted by the whole {context, intention; atmosphere, atmosphere} then we will have a halo³⁷ as long as we agree to call "moment" also. This is the moment we envision when we let's talk about forms that depend on the moment.

Living beings depend on the moment.

The Ark of the Covenant was designed according to the moment (it also contained the first Tablets that Moses broke, those that were written on both sides).

The first Temple in Jerusalem depended on the timing for some of its dimensions which had been thought out from a moment-bound unit. In this case, we cannot compare this unity to another as long as the Ark, the Temple are not finished, this is a reason for which, during the time of construction, it remains secret. So measure the cubits Egyptian with a meter is useless because if we reproduce the form - as we will say "exactly" - it will not be exactly the form of the past; she may or may not depend on a moment but it is not the moment of the first form. Besides the first Tables depended on the moment of the fact, in particular, of their localization on the Sinai. Moses, breaking them, removed a moment at which, as a form, they were associated. By placing the pieces in the Ark of the Covenant which was also linked to a moment. Moses was able to find for these pieces the moment linked to the location of the Tables. This caused the Ark containing the pieces to be bound at two times. A shape that depends on when retains its properties. If played at another time, it will possess other properties while appearing identical.

One can thus find a unity with a view to the realization of a form which will have to have such or such property; this unit of measurement should under no circumstances be compared to another unit, for example the meter or its multiples and sub-multiples. Thus we can make a wooden parallelepiped with amazing properties, stable over time.

In alchemy it is necessary to take into account the moment, from which a certain number of grimoires become unnecessary. They only have historical value; he who has understood this operates in a true supralchemy.

³⁷ These concepts and writing will be explained later in the course.

In the teaching of certain initiates, thoughts of these initiates cannot be taken up by other people at any time; as forms these thoughts depend on the moment. The disciple is the one who is close to the Master, formed and chosen by him, and to whom the Master gives the power to resume the teaching, at another time perhaps, but in keeping him "all the substantive marrow" as Montaigne would have said.

Is a form which does not depend on moment a degeneracy of a form which depends of the moment despite the fact of feeling unconstrained by the moment gives an impression of greater freedom? One must be wary, in the domain of forms, of what one thinks one gains; one can, by gaining too great an adaptation, as is done in rational science, lose a fundamental essence; in a sense a moment-dependent form is more an emergence only a form that could be called "free"; which does not mean that a free form does not is not in some cases as delocalized as a time-dependent form.

"Non-locatable" forms are forms of which we only have an index, which is, in general localized. It is this index which is used to use this form; she is not us accessible only by this index. A non-locatable form is itself more or less close location; it seems to "oscillate" towards a localization that is called form-index.

An example of such a form is obtained by planting in the ground, vertically, two stems of iron, circular, of the same height (circular section, height 1.80 m. or more) so that that the plane formed by the two rods is oriented northeast/southwest. So we detect a non-locatable form whose two poles are like a start of localization. This shape can serve as a good rebalancer and emitter in a certain neighborhood; we can still amplify these properties by placing, on the ground between the two rods, a block of quartz (all minerals do not give this effect).

Another example of a non-localizable form is boron hydride - we are in the field microscopic - of formula BH_3 . In reality it is placed in the usual C. of C. in the form B_2H_5 . B_2H_5 is an index form, well localized here.

The "barred" forms were discovered around the 1980s during research.

Let us now see such a form. For this, let us draw in a plane a rectangle ABCD with center of symmetry O as well as the two axes of symmetry, perpendicular to the sides, $x'x$ and $y'y$. Let us now draw the line $t't$ passing through O and making an angle of -23° (or $-22^\circ 5'$) with Oy .

Let's delete the axes of

and

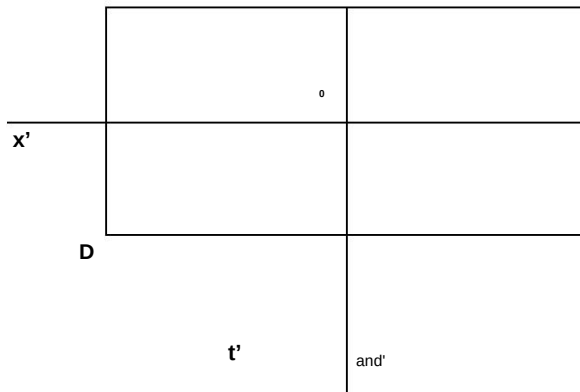

symmetry. This figure will be called "barred form". He is

interesting to note that this form emits at high

g fields of Taofel38. A matter of direction

in the plan arises which we will not discuss

in this course [iv] and [v].

x A rectangle can be replaced by a

square ; the more one tends towards formless forms.

C the more delicate it is to cross out the form, but it is

generally possible. You can cross out a circle; he

must then be very careful to impose the "North

said of form" [iv] and [v].

A barred form can depend on the moment.

Let's bar a rectangle placed vertically, the North of shape is then replaced by the vertical

ascending from the place. Depending on the position we have in relation to the plane, the shape will be crossed out or

no. Thus two observers will have different opinions as to the form. Which is right? Yes

the strikethrough form has effects on the environment, for example vegetation, what will

be chosen by the place, or the form, seen as barred or not barred? The two observers

are right ; they may very well disagree. In one place, two realities

exist, one is chosen; so does the environment. But the two realities

which each come from distinct representations may very well be in tension under

the many faces of tensions, some of which we will study later.

Shapes with "variable eifs" are also found in the case of a star pentagon

regular where we carry at each vertex a segment of constant length and making the same

angle α with the tangent to the circle circumscribed at this vertex. The period T is a function of

the angle α . Check this in practice.

Note: The pendulum above such a shape turns then its movement slows down,

then increases again, and so on.

"Decal type" shapes:

- Consider a form F!
- Let us impregnate or dilute this form in a bath, an atmosphere; this will give F'!
- Let's tackle F'! on a support, this gives F2

See the rest of the course.

Suppose that F2 turns out in F'2 .

We will say that we have gone from F! to F' following a "decal type" process.

We can then combine F! and F' in multiple ways, by voltage, by a T AG system, which will create an atmosphere.

We talked about dilution, let's see the dilution of existence. Dilution can be done in existence with landmark or without landmark; we therefore have existence diluted in existence. this generalizes the notion of diluted form.

We will see the forms related to the aether in the following booklets on the eifs, the avaecum, but we need these concepts and results to present this type of forms.

Exercise: We have seen the barred rectangle. Let's place it vertically with its bar.

- 1) Check that it is still "crossed out" and that eifs are detected which are at the EFF level and at other levels.
- 2) Suppose that in this position an observer arrives on the other side of the plane. To verify that it is no longer barred.
- 3) What do we detect around this vertical plane in which the barred rectangle is located?
- 4) What can we conclude about such a situation?
- 5) What will a plant that is close to this vertical plane choose?

Answers:

- 3) When we are on the side where the angle is -23° , the rectangle is crossed out; we detect eifs which are Taofel fields - which we will present in forthcoming booklets - and this on both sides of the plane.

When we place ourselves on the side where the angle is 23° , the rectangle is no longer barred. We detect eifs at the EFF level but no Taofel fields.

Conclusion: the nature of the eifs depends on the position of the observer.

- 4) The plant, living system, chooses according to its nature, a position of the observer; what whatever her position. This can change over time, from one representation to another. Perhaps even tensions between the two possibilities may introduce themselves and set up new possibilities.

If we come back to the human observer, what he detects in front of a form may also be the result of stress.

The observer seems to be faced with a problem of broken symmetry. What is even more interesting. What must be achieved is what is before the breaking of symmetry.

Forms allow access to this “before the breaking of symmetry”. For example certain Hebrew words, more generally certain flat shapes, water in which one has put some message, etc...

In the couple man-woman (HF) the difference between F and H is the result of the breaking of symmetry.

We have to go back to the Bible on this subject and we begin to understand what it is.

Conclusion :

The realm we are entering is truly confusing. This justifies the remarks on to which we returned in the course of the 1st level, where everything, absolutely everything must be carefully observed before drawing any conclusions.

There are many other situations like this.

Course
2nd level
Paper 11

November 97

I. Introduction

Ancient books are full of bizarre stories, observations that seem incomprehensible because absurd; the old people talked about it in the evenings, the adults mothers told these stories to their grandchildren. All oral or written transmissions are full of them; but we must not sweep away tales and legends under the pretext that they are not that nonsense and stories, thus are they considered by too hasty a judgment and by people who want to be strong, rational.

We must then ask ourselves if rational thought is adequate to allow ourselves to do bring out a reality, a likelihood of a legend, a tale.

Of course, it should not be inferred that every story written or told is full of hidden mysteries, which a hidden key also must surely, if it is implicit, open on a wonderful world. Thus many so-called alchemists speak in hushed tones of mysterious texts, comprehensible only for them and draw from them an attitude of rejection and disdain vis-à-vis others which - they have the impression - enables them to value them vis-à-vis others. They know - so they think - and the others do not know.

Forget those failed alchemists - luckily not all alchemists are like this and a few were exceptions.

We must not forget that human beings have the right to dream, to write novels, to tell stories. But some dreams are blossoming flowers, each representing a deep human feeling. This was the case of Jules Verne who imagined in the deepest sense of the term: he was already in his creations!

In any story we can set up a path to extirpate, in the course of this way, of this Way - in the sense in which we spoke of way in the 11th booklet of this 2nd level - knowledge that will reveal the contents of a decryption if it is a document coded, from a study of the human mind because all thought, all expression of thought, is it even a "face" of a being, - the one who created the text, the story - from a form - form to very broad sense, not only in the sense of material form, so a thought can be a form -.

Above all, we will not stop at the usual studies of character, sensitivity, quality of an author from his text. Theses, newspaper articles, journals on these types studies are legion.

The study of the work of Balzac, for example, is a source of stories which, in addition to the interest that each novel brings, describe the mores of a society and the characters and actions

of characters. But we can consider this work quite differently. She will intervene on the reader's brain as a springboard to something else - you could say it's a source d'inspiration-.

Thus these works like "Les Centuries" by Nostradamus have given rise to multiple interpretations. There were absurdities but some contained a fundamental message: it seems that this text is a cornucopia from which many revelations could emerge.

It is then necessary to realize that such a text or even that the work "The Bible, The Code Secret" by Michael Drosnin are constructions that are not made in the so-called thought rational and that by rational thought, by leaning on these writings, we find ourselves before a multifaceted system. The decryption processes are as many indicators of these texts. They are lit each time in a different way.

The excitement of the one who discovers a hidden meaning is great. Everything seems to come together in him. There is seen a coherent construction that will go more and more in this direction as the investigation of the text.

And for the future, these decryption texts and processes become manias.

Tip: This introduction should be read carefully and re-read. The student in this field, the reader, must become impregnated little by little with the thought in which we introduce them in order that they train themselves to think differently and to even be able to contemplate rational thought without having to bear it as is the case when we consider it unique - so it is the case in our society which wants to be modern and in continuous progress -.

In each booklet, one will find such studies. It is therefore necessary to study them well - to read and reread; so is it necessary -. They are like the exercises and problems presented in each booklet.

Students need to get off the "beaten track", go against the grain and that they doubt the certainties that have tacitly overwhelmed them; to agree to open up to a new thought.

Traditionally accepted research must be considered as a very special case, and by its form of thought, and by its methods as well as its consequences, achievements technology, economics, sociology, etc. all of which rely more and more on the Aristotelian logic, on the "Cartesian" mind, both of which are moreover useful for compare, classify.

But in any research, one should not classify too quickly because one can break something something very deep by wanting to see too well: a classification always has a horizon that he cannot reach and this horizon may very well not be in accord with the system of employee classification and disappear when the induction-deduction grid falls on the observed area. This horizon is the index of an instability, which is not considered admitted in the usual thought, but which manifests itself for the one who has the consciousness of another form of thought.

In the group ARK'ALL we looked for another way; to do this we tried to put together researchers who had sensed the need to think differently. It's this trend, this effort that will make the cement that will bind them and stabilize their rapprochement in the same group.

The field which has thus been opened up is so vast that it is impossible to write everything down. It's necessary above all to make aware of those who want to get out of knowledge and backgrounds traditional that he can and must attempt a breakaway, a jump, and above all that he is not, that he is no longer alone.

ARK'ALL then the DECALUM association and the EUREK'ALL Company placed in these courses ideas that will spread among peoples; these ideas will accustom the public, peoples to accept what may seem strange. We will have to adopt the following attitude: if a fact seems unacceptable, rather than hiding it or rejecting it, we must change our reasoning.

Through this new discipline of thought, facts that are rejected or distorted - because they are incompatible with the Cartesian system of thought- find themselves immersed in the same bath and become understandable.

Arkalian research applies, in its approach, to reinjecting the methods of

The approach. This is very important and must be meditated on because so to seek it is in the working atmosphere which reflects the spirit he has adopted. It "is being".

Finally, it is desirable that the readers who will necessarily be faced with words new ones or known words but used in a completely different sense, do not to distort what they are supposed to mean here. These major drawbacks tend to

bring the reader back to what he knows or to make him appropriate the terms new to use them in contexts that destroy them instead of enhancing them - this last attitude obviously corresponds to dishonesty There are also those who misinterpret concepts.

**“Now if you have understood (the Philosopher tells us) you have not
no longer need my explanations... and if you don't have
understood is that you will never understand. »***

Jacques Breyer

- This thought concludes Jacques Breyer's book "Terre Omega"[5]. Jacques Breyer worked for nearly forty years. He was part of the team which, at the Château d'Arginy - near Mâcon - from 1947 to 1952, tried to revive the Templar Order and achieved very spectacular results in the octagonal Tower known as the Tower of the Beatitudes, as much day, inside, as night outside.

Note: we must deplore the terms improperly used, especially in the field of forms.

The words "magnetic" and "electric" chosen by Bélizal and others are confusing with the true electric and magnetic words of physicists; they could, without damage, to be replaced by others. This is the reason why we took E for electric and M for magnetic avoiding pronouncing the two words but simply pronouncing the letters E and M.

It is the same for the aura which intervenes in the diagram of the vital field. It's not the aura view around the human body. This word was established by analogy - in the rational sense of the term - of the aura of the human body.

Exercise :

1) Check that in multiple places where there are electrical equipment,-

household appliances, TV, sound systems, amplifiers, electrical installations under plaster, sockets running along walls, etc. ; we find a state | QTL > - QTL in Hebrew means to kill, murder, shoot down [i] -.

2) Check that QTL - the word - corresponds on the disc or on the transmitter square to an eif close to Re.

a) Build a 19, 9, 12 cannon first. To avoid orientation place a small nail to the groove separating segments 9 and 12.

b) Hold in the hand by the segment 12. It thus leaves this eif which one finds on the square transmitter (or on the transmitter disc).

3) In general this eif does not have this state | QTL >; check it.

4) Check that the status | QTL > is the same as state | K Error! Bookmark not set.
Sh R >.

Error ! means: to accuse someone, to hold a grudge, to bind, to tie, to complete, to conjure against, to be tight, to be robust, to be strong (here the point on the Sh is on the right; naturally as one signaled it in the course of the 1st level the point on the Sh is either on the right or on the left but never in the middle; on the other hand, to detect in the domain of forms, it must be moved to the environment).

5) Check that a 19,21,22 barrel with a small nail planted in the groove of the 21,22 and held by 22 sends the same eif as before.

6) In general this eif does not have the state | K Error! Bookmark not set.
Sh R>.

Note: J. de la Foÿe remarks [ii] that a farmer he knew had asked to locate underground water passages in its orchards in order to avoid build the house he envisioned on it. Let us immediately point out that we can construct houses above such places but then consideration must be given to the shape of the house and no longer think that this form must be sufficient to block any harmfulness after the people who will move into the house can furnish it according to their aspirations without modifying the balance obtained. This can easily be done by people like Serge Henneman, Philippe Arnault, Bernard Menguy of the ARKOLOGIE¹ Association and by people like Luc Labat and Sophie Nouvel from the BARKA^{1 2} Company. you have to be careful with certain people who call themselves geobiologists because the geobiology, very often, does not allow working so subtly as people of ARKOLOGY or BARKA. Geobiology wants too much inspiration from rational methods and their approach and way of thinking are very Cartesian and are inspired by the models usual.

J. de la Foÿe, about the request of this farmer, did not detect anything, on the surface, of harmful for vegetation. The house was built; it didn't change anything. But on a narrow band of land, at the end of a field of beets, the lawn surrounding the house had become like a desert.

First approach to the neutral pendulum: we felt a harmfulness.

Then the state $|QTL\rangle$ was detected with the appropriate pendulum.

This state could be detected from a recently planted EDF pole; equipped with lightning arrester ground to an old hay rack with parallel bars left about a hundred meters from the post.

The rack, at the request of Jean de la Foÿe, was removed. After a few weeks the grass and the beet leaves were beginning to grow.

**Conclusion: States were found $|QTL\rangle$ or $|K$ Error! Bookmark not set.
Sh $R >$ in others places of other places; for example :**

- between a flour mill motor and a television antenna.
- Between a manure exhaust motor and the earth connection of another appliance.
- between a cast iron stove and a gutter.

¹ Association ARKOLOGIE, 77 rue de la République, 93200 Saint-Denis
² BARKA Architecture, 31330 Launac

between two bedside tables on either side of a bed.

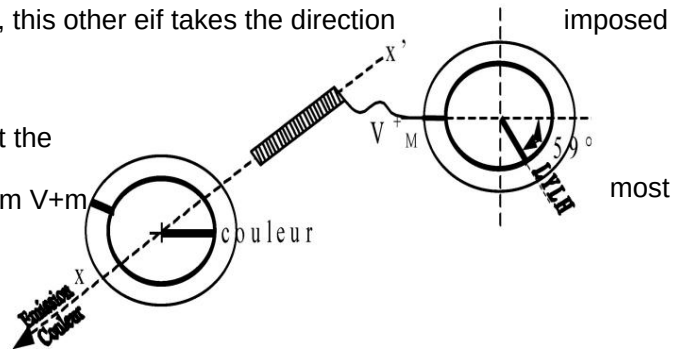

The latter case occurs quite rarely.

Exercise: We build a radius disc out of wood or cardboard - scratched on one side, smooth on the other -.

The free face is placed against the plane of a table - without a drawer - and not above a foot.

Check that LYLH is detected above and hA WR on the unscratched part. 1)

- 2) Check that LYLH is detected at the tips. YE HJ
- 3) Check that a grooved board like opposite emits LYLH on the side of 5. For this, we plant a nail between 10 and 12.
- 4) Check that at LYLH there corresponds an eif close to the UVle located at 60° , in reality the eif is detects at V^+_M on the transmitter plate, when the needle is very close to 59° .
- 5) Check that if we have the eif LYLH in a given direction and we have another eif of undifferentiated or differentiated spectra, this other eif takes the direction imposed by the LYLH
- 6) Make the montage3 [iii] and observe that the indicated color does not come out at $V+m$ $V+m$ next x'x.

he. Overlap: Experience and Energy

Consider two types of crystals: quartz and obsidian. They will appear under form of formless blocks: the first constitutes an F shape and the second an F' shape.

Let's place the block of quarters F on the block of obsidian F'.

1) Check that new eifs4 appears.

Note: We will call such a montage a ///////////////

overlap. But it may happen that:

- 2 shapes F and F' will absolutely not be in this position and one will overlap the other.
- That 2 forms F and F' are such that F overlaps F' but F' overlaps F - one is apart from the usual representations, it should not be forgotten -.
- A human being may be ridden by another human being; it happens ; Where by an entity; or by a group of human beings, or by an animal, or an element of the vegetable kingdom, or any other form; even by place.
- There are overlaps in Voodoo. Here human beings are overlapped by snake-like entities but many others are possible because their number exceeds 800. Let us point out that concerning the overlapping by the snake, it is the overlapping of a people's knowledge of the serpent entity; what will be called later: the Enel attached to the serpent.

In the Voodoo cult overlaps are sought. Human being, when overlapped should not be seen - as a form - as a being human. It is our tendency to locate in the field of rational coherence (C. of C. rational or usual) which makes one return to the localized form.
- Notation: F' overlapped by F will be written: F'f

2) Use the previous montage, ie F'f to soak up the concept of overlap.

Advice :

4 This is because it was assumed that the undifferentiated and differentiated EFF spectra do not constitute all possible eifs.

You have to be careful, when working on the shapes not to be made overlap by either a form, a set of forms, a state, a being etc. By For example, a very great fear can create an overlap.

- When working on a form and it is difficult to detect the eifs of a form, its states, one must ask oneself if the form is not overlapped. If it's the case, you have to think of this overlapping form and completely detach yourself from the usual representation.

3) One can also find overlaps between numbers. That's what had foresaw Georges Barbarin [iv] who had proposed $I_1, I_2, \dots, I_N$ where N and P are integers positive. He thus spoke of rider number and horse number.

A number overlapped by another does not give a number. The hypothesis presented in the work of Vladimir Rosgnilk [v] is perhaps not the right one; indeed we had assumed that to N_p corresponded what has been called Cumulo-Decalary Arithmetic⁵. But this hypothesis will not be accepted for the moment⁶.

4) It can happen, when testing human beings, that a person is overlapped and

one	state,	by	example	genre
Error! Bookmark not set. K Sh		Ph with Sh	Error! Bookmark not set.	knocked down > be placed

on this new form - the person being ridden -. We thus arrive at states very pollutants and delicate to annihilate.

⁵ These expressions will be presented later in the course.

⁶ Naturally the writing ab used in mathematics where a and b are numbers absolutely does not correspond to an overlap.

Chapter III

Taofel fields

Obsidian (one block) overlapped by quartz⁷ (one block) led us to discover new eifs. They are called Champs de Taofel.

We were able to classify them.

But whereas in the case of the EFF eifs there was no ambiguity, here we are faced with an instability that attaches to the concept of Champ de Taofel. The concept itself is not stable, it leaks.

In this domain of forms, like the flight of reference points - which we mentioned in level 1 - leakage of concepts will often occur. This does not bring indeterminacy to impoverishing character but on the contrary an immense richness emerges from these concepts and landmarks on the run, wandering.

We discovered the fields of Taofel by operating a device invented by two researchers Léon and Marie-Thérèse Sprink.

Thus the first two Fields of Taofel⁸ (C. de T.) were felt.

They had also been discovered by two other researchers who were working on the forms, it is about Lucien Chaisemartin and Morel, this shortly after the second war world. They were the ones who had completed the so-called "fictitious cone" pendulum and some of these pendulums, at least the first series which was put on sale included 2 graduations supposed to correspond to the first two C. de T..

They called them "vertical emissions", the others of the EFF level being called "horizontal emissions". We are going to extend our research to these famous C. de T. and for this study in detail the work of Léon and Marie-Thérèse Sprink.

⁷ These are not obsidian and quartz entities.

⁸ Taofel field: abbreviation C. de T.

SHAPES AND ELECTRIC FIELDS

Leon and Marie Therese Sprink

Léon Sprink was born in Russia at the end of the 19th century, he died in France in 1967. He is buried in the Russian cemetery of Sainte-Geneviève-des-Bois. His family was of Baltic origin. Very young, he was very imaginative and curious about what interested him; report the sighting that he made of a solar eclipse while he was in a field belonging to a property family, quite a special eclipse, the solar plasma had taken the form of a cross of Saint Andrew. His father, before the war of 1914-1918 took him to visit the beer factories of Moscow. The beer obtained in these factories was of rather poor quality and the fermentation hops took too much time according to the technicians present. They had no remedy to reduce the fermentation time and increase the quality. Young Sprink, returned home, asked his father for permission to work on the fermentation of beer. His father gave him the elements and he imagined (he must have been about 16 to 17 years old) shapes of fermentation tanks as well as the alloy which was to compose them. His process was applied and the quality of the beer was singularly increased as well as the hop fermentation rate. But during the revolution in 1917, the crowd entered the factories and smashed these vats with sledgehammers..

Anyway, even if the tricks imagined by the young Sprink were lost (we could find equivalents now), the beers made in our time are quite good and the fermentation speeds sufficient not to repeat the problem (we should point out that some beers now contain dyes and other chemicals and that it would still be preferable to treat them by a Sprink type process, this would increase still taste and would make a very healthy drink). The Russian Revolution did not spare them Sprinkle. He was locked up in the "Peter and Paul" prison in Saint Petersburg. There he was tortured. (He has moreover, in this prison, witnessed the agony of a very famous Pope from Russia). It should be noted that he was one of the rare survivors of this prison; indeed there were only 3 or 4 people who were not murdered there. He arrived in France and was declared disabled at 99%.

He met shortly after a young widow, Marie-Thérèse Roussel with whom he married. She died in 1951 of cancer. She was remarkably smart and they started their research.

In 1923 L. Sprink was in Strasbourg, in a chemical industry factory: a stearinage. He was the owner of a process for manufacturing soaps with high detergent power that the factory in question had adopted. There was a research laboratory, admittedly modest, but the factory was at his disposal for industrial checks.

The results of the application of these soaps, especially in raw wool washing plants (in Alsace and in the North of France) were more than satisfactory.

But now, after two years, there were setbacks and irregularities in the yield. First of all, the cause was sought in the difficulties specific to the implementation of an industrial scale of a process established in the laboratory. We wasted time checking the process itself as well as its theoretical bases.

This factory still had a boss, born in this factory and master at home. One day he reproached L. Sprink of "looking too much for noon to two o'clock" and he added "You know, the recipes for manufacturing last only for a short time, without there being any need to modify".

There we recognize, in this reflection, the point of view of the industrialist who is always in too much of a hurry and too poor in solid bases of understanding of the mechanisms. It is the contribution of research laboratories (in basic research) which then becomes valuable.

It therefore emerged from this interview that the manufacturing process as such was perhaps not the cause of these performance disturbances. We had to look elsewhere.

At the time, the manufacture of soap in this factory was too recent to establish a scale for comparing the presumed variations. On the other hand it was not the chemical analyzes of its composition which could inform. There was in the end

9 What relates to the life of L. Sprink and his wife as well as their attempts was reported in the notes of the couple as well as their "logbook" which they kept very well throughout their career of researchers. We will not discuss here in detail the scientific personalities they have touched to make known and share their work. Their steps would be the subject of a volume - hopes and disappointments followed one another as for all these researchers who worked in non-Orthodox fields -. Let us nevertheless mention the meeting of L. Sprink and A. Einstein which took place in Germany before the departure of the latter from this country. This meeting was memorable: it lasted an afternoon. Einstein proposed to the Sprinks to go to the USA where he was already thinking of going. The Sprinks during the 39-45 war remained in France and worked near Grenoble). Einstein gave Sprink his thoughts on his work. It can be summed up as follows: "I work by breaking down and you (L. Sprink), you work by assembling". Einstein had really seen Sprink's approach and that is what is essential because in this area the approach is different from the usual approach.

than the results obtained from users. There, we knew that the soap was more or less good; therefore variable in quality.

This soap was made with fatty acids produced at the factory. L. and MT Sprink have therefore started by studying the results of the laboratory control of these products. Immediately he They were presented with the averages per month and per year, as well as the yield figures for factory. The averages per month, taken step by step, were not very clear; on the other hand the averages per year turned out to be much stronger for certain periods with sag before and after. This was especially striking for the years 1911 and 1912.

Autoclave study:

The first processing operation in a stearin factory is saponification:

breakdown of triglycerols into glycerin and fatty acid. In the factory in question, this operation was done with autoclaves, under the constant pressure of 10 kg/cm² with direct heating at 180° by steam. It was done in two stages:

- Five hours under pressure - one rest - water change (otherwise the concentration of these waters in glycerine would have slowed down the reaction), a rest of twelve hours and an
- pressurization for three hours.

This walking pace, found empirically, gave very good results at the time. After the first five hours of walking and at the end of the operation, we checked the results at the laboratory. As there were four autoclaves in operation every day, we had 16 index determinations per day. This made it possible to group the indices of the saponifications and the acid numbers by four, which initially avoided excessive differences, due to anomalies that could occur through fortuitous causes. This is why and also because saponification was closely dependent on the yields of the operations later manufacturing, that the Sprinks put this data to close scrutiny.

Immediately, they had to realize that with the system of averages per month, there is had nothing to do.

Faced with this semi-failure, they fell back on statistical methods, while keeping to their respect a certain mistrust.

The construction of frequency curves of a discrete numerical series, which gives the number of cases for a given result, obviously provided them with dispersion curves of results (Gauss bell curve).

But the Sprinks therefore attached themselves to a statistical law in order to deduce results from it. to exploit. It should be noted that their device did not work quite rational and that the view advocated by M. Beigbéder [vi]: a statistic depends on the mode of reasoning chosen and the statistics used to date are within the scope of usual consistency, was not known to them - Mr. Beigbéder's book coming out in 1977 But L. Sprink was sensitive enough to smell:

- that his camera was not quite a technical object and
- the fragility of the use of statistics on the operation of his device.

On the other hand, he had to get industry to accept his results as well as his manuscript at the Academy of Sciences¹⁰. On the other hand, we can apply a statistical law to the phenomena studied by the Sprinks, in particular saponification in a stearin factory.

This digression was necessary to show the caution with which one must approach these phenomena and know the field of coherence in which one must place oneself.

The first surprise for L. Sprink and his wife was to find that, despite an average statistical (most common value) and which was by no means what they considered important (which she was the considerably lower arithmetic mean) there was on each curve not only one, but two or three characterized maxima. But what surprised even more, it was the statement, absolutely unexpected, that from month to month months, there was a coming and going of the location of these maxima. In other words, at Statistically, the response fluctuated more or less widely depending on the time of year. It was then that the idea came to them to arrange the daily results in the form of a curve, where the ordinates were brought in proportion to their numerical value and they have finally seen a certain periodicity appear.

Obviously, we knew "by experience" that, for example, the yields of autoclaves varied with the seasons and yields were higher in winter than in summer. Had even found for all these irregularities a perfectly plausible explanation by the bass winter temperature - autoclaves obviously cool much more than in summer, there is therefore more steam entering an autoclave in winter than in summer - hence a greater agitation of the materials in reaction and a greater dilution of the glycerinous waters. But this explanation does not correspond to the actual state of the conditions. However, as often happens in similar cases, this had prevented further research.

¹⁰ L. Sprink deposited at the Academy of Sciences a manuscript composed of 2 parts. The first was only descriptive and the second an attempt at a theoretical approach involving conformal transformations and propagation results of an electromagnetic field.

To begin with, a quick harmonic analysis revealed a period that corresponding to the 28 days of the lunar period. Under these conditions, the grouping of results per month obviously could not give anything very clear.

The simple fact that the two consecutive maxima were in reverse order at spring and autumn showed the Sprinks that their autoclave-related curves followed the rhythm of the tides. But to neutralize the tides, there is no way!

There was still an anomaly that put them on the right track. We have just said that autoclaves generally worked better at the winter solstice than at the summer solstice. However, the tidal indices are the same at these two times of the year. It was therefore necessary find one more variable that is periodic and this period had to be the same as the one of the operation of the autoclaves. Among the curves established by their care, there was one which related the results obtained from the autoclaves and the times they were put under pressure. The results followed the curve of variations in the earth's electric field. He is known that the field is relatively more intense in winter, in dry and cold weather, and that it is thus much more stable than in summer.

This last observation left them very hesitant for a long time.

An autoclave being a completely closed container with walls approximately 50 mm thick pure copper, so it's a Faraday cage. The Sprinks still wondered if this was not another phenomenon that was alone, the real responsible.

Fortunately, they were able to consult the original publications about the Faraday cage. This is very interesting because going back to the sources of the work we find experiences detailed and also the reflections of their authors. Publications and books were still, fifty years ago, much richer in detail. The "academic" style presentation that we now find that researchers believe they are working on solid concepts, and even some do not know the reason for certain hypotheses. A hypothesis, a axiom, are often the admission of ignorance and their role is to gather intuitions various. Know these intuitions, bring them out and immerse them in the middle of your thoughts personal allows them to be given new life; and also allows finger touch the weakness of certain theories, or to feel other approaches. Machines built in the 19th century have, for some, come close to the relocation of their functionalities; this is how Tesla even in the twentieth century was able to obtain rather curious effects. He had observed electrical actions which seemed to him outside the usual laws. If we consider electric motors, there were more than a thousand models made by multiple inventors

and very few have been preserved (like the one called "in a squirrel cage"). People had imagined bizarre windings, and so in this case, at the level of the axis of rotation can appear decalaires or channel and emissions with high Taofel fields.

The search for localized principles has resulted in the unorthodox cases being dismissed or forgotten. As it was believed that only the principles attached to localization (the concept of localization and trailing landmarks being ignored) were the only ones allowing to describe the universe, we have made the technical objects after them and the other objects which were not of the class of technical objects, have disappeared or have remained memories of no interest.

By consulting Faraday's original publications, the Sprinks realized that, as the author himself pointed it out: the Faraday cage is only valid for charges electricity in balance.

In an autoclave, heated by steam, this is by no means the case because there is continual supply electrical charges. They had conclusive proof of this by dropping these charges at inside the autoclave which greatly reduced the degree of saponification.

So they put the autoclaves in an electrostatic field in such a way that its value was large enough to neutralize as far as possible variations in the earth's field and so that the values that seemed to be "threshold" values for the can be exceeded great efficiency.

The success was overwhelming and spectacular (it happened in 1933-34). After a few months, with the new regime, it was possible for them to draw some provisional conclusions.

- 1) From the point of view of the quality of the goods there was a notable progress. The clues of saponification and acid were higher than with the old step and joined the saponification indices of fats and oils, when they were loaded in autoclaves. This fall in the indices at the exit of the autoclaves was intriguing, it is especially for this that the Sprinks had made spectroscopic measurements before and after passage of the material in the autoclaves and had demonstrated that it was due to chemical condensations of fatty acids and oxidations. The removal of these reactions gave them a clearer product but above all a less acidic pH. Their products thus benefited from a new application: cold paving. On the other hand the fatty acids now crystallized much better than before, which, in a short time, increased the yield at the presses (hot presses) and thus amplified considerably the production capacity of the factory in which they were experimenting.

The amplitude of the variations qualified as lunar by their care was considerably diminished. On the other hand, for the annual curve, it was less clear.

2) Autoclaves: for autoclaves, they have obviously adopted a course different from the one before the tests. We will not develop their method; it would lead to overly technical details.

They continued their work. Mrs. Sprink studied the formation of cements at low temperature. She had arrived at a very fine process for making ammonia.

Unfortunately, this process required special design ovens that the industry does not could afford to build especially at the time of the great industrial crisis of the years 30, which had seriously affected the cement industry. 30, which had seriously affected the cement industry.

So they thought the difficulty could be circumvented and get a massive saving of combustible by using the installations which L. Sprink had just applied to the autoclaves.

He had two reasons that encouraged them to try the experiment:

- 1) the decarbonation of limestones is from the same group of reactions as the saponification of fat body,
- 2) L. Sprink had observed a very strong increase in temperature in the autoclaves. Very troublesome to autoclaves, since it hindered the circulation of steam, this exotherm represented a huge advantage for the ovens.

This increase in exotherm had initially left them perplexed. It may seem that the principle of energy conservation of an oven is only 20 to 25% of the energy supplied.

It could therefore be admitted that quite simply the efficiency of the oven had been increased.

This is the explanation they adopted. She doesn't really explain anything, but at least, has it been found satisfying to the mind. This is often the case in research where a explanation that is not correct but reassures the mind, allows the researcher to remain in "the beaten track ". Fortunately Sprink had fully sensed the danger of such an attitude.

This "exothermy" remained variable, as did the yields and results at the stearinage. It even seemed that the deviations from the new average had increased. It was therefore clear that an additional factor of which they were unaware was at play. But it was certainly not not the terrestrial electric field nor the lunar tides.

Previously we saw that these same variations were also manifested in autoclaves but in a much less clean way and moreover not very inconvenient for the application of the new process in the fatty substances industry, the desired goal having been achieved.

Such would not have been the situation in the cement industry. In fact the qualities of cements, in their furnace, and especially the resistance were very variable and followed curves inverses of fuel consumption.

Thanks to some observational data, few in number, but which could not be regarded as fortuitous coincidences, and discarded for this reason, the Sprinks are arrived at the quasi-conviction that these disturbances depended on the solar activity, become more apparent by the suppression of the much shorter period lunar effects.

last result can obviously be obtained by harmonic analysis, thus demonstrating the existence of these larger periods. But at that time, harmonic analysis had a very great defect: it eliminated all accidents. But they only had these to guide ! Based on certain observations of the solar corona, very quickly, they realized that it was through this that the solution of the problem that fascinated them would come.

Until the war of 1939-1945 the solar corona could only be observed during solar eclipses. Since then, observations have been made as regularly as possible but of a still insufficient duration (covering two to three solar periods) for them to be able to even in 1950 (these studies were carried out since that date but the Sprinks had thought about it at length) bring decisive elements to their studies. (Note that the corograph of Lyot only dates from 1937).

They could see that the best returns in the industry occur 3 to 4 years after maximum internal activity. This excluded the influence of sunspots in a meaning as in the others.

It has long been known that the aspect of the solar corona changes over a period of solar activity. Very intense at the time of maximum solar activity, it is at this time evenly distributed around the sun and especially at its poles. At least she is highly developed in the direction close to the equator. In the intervening epochs, his form is intermediate. At certain times, it has the shape of a cross of Saint-André. And we will focus particularly on such periods.

Here we are faced with a form which presents itself in a certain way to the observer; it will obviously not be the same for all the observers (example: an observer lying in space in a direction at 90° to the earth-sun line). So the eifs

detected will not be the same. Objectivity and subjectivity here disappear. Just do a simple experiment to be convinced of this: if we consider a magnetic field horizontal and that we put in this magnetic field produced by 2 magnetic bars cylindrical a cross of Saint-André, we will observe certain effects. If we rotate 45° this cross of Saint-André, we will observe other effects. But if the observer turns 45°, at instead of turning the cross of Saint-André, all the apparatus remaining fixed, he will not find not the effects of the Cross of St André.

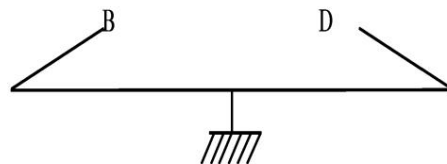

The registration is here relative to the horizontal for example.

In the case of the sun, it is relative to the line passing through the observer and the center of the Sun. We therefore have correct identification and no ambiguity on the observed cross.

When we speak of the cross of Saint Andrew, without attaching ourselves to an apparatus to which it can to be associated is that one tacitly assumes the notion of horizontal in relation to which it is placed. And in this area of the effects. - C. de T. and associated states must always be kept account of this tacit knowledge.

Recall that L. Sprink, as a child, in Russia, walking on the lands of the estates fathers had had the chance to contemplate, during an eclipse of the sun, the crown solar but in the form of a cross of Saint Andrew.

It was therefore, as we have already pointed out, shortly before the war of 1914 and this in extraordinary visibility conditions. He drew from this memory the image of two landfills crossed between four points, and being made between the diagonals of the square joining the points. (Naturally the tips are supposed to be placed so as to $\wedge$ $\vee$ distribute the correct symmetry)¹¹ In electrostatics, $\vec{E} \cdot \vec{r} / r^2$ on learns that in this case, without going into details the $\vec{E} \cdot \vec{r} / r^2$ discharge is done along 2 sides of the square AB and CD.

¹¹ It was Marie-Thérèse Sprink who reminded him of this.

Course

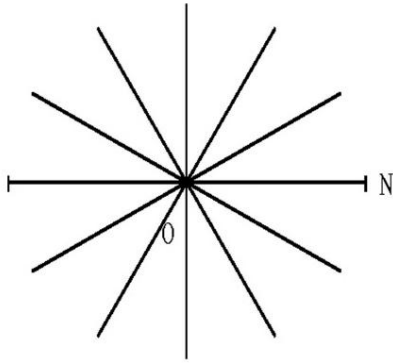

2nd level

Paper 12

December 97

2) Dynamic duality

Let us consider 2 shapes A and B and the shape constituted by a segment MN of middle O. In

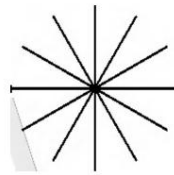

M and N are placed two legs. Moreover let's trace a circle with center O, radius $OM = ON$ -

circle which is only an intermediary of construction, it will then be erased Let's draw the diameters at 30° , 60° , 90° respectively from MN.

If such a shape is detected between A and B, A and B will be said in Dd

We will see during the study of the Ying-Yang, the heuristic approach of the Dd.

We will write that A and B are in Dd by A I-----1 B.

We will carry on a cylindrical pendulum the form the Dd.

which makes it possible to detect

3) Numbers crossed out

Consider a shape A and its image A' in a plane mirror P

P

In physics A' is said to be the mirror image of A

£ _____ íx plan P.

S0ít A '= IttlpA

So let's now consider the process we put in place in the course of

I 1st level: A----->ImpA; so we set up a path; let's apply this way to whole numbers 1, 2, 3...

Thus N-----> <-----this will give N so let's write it and call "Numbers

crossed out" these new elements. We cannot compose between them for the moment, the crossed out numbers.

4) The fields of Taofel (C. de T.)

We have therefore listed the C. de T..

Thus we find 11 1 1

2 I 1 2 $\tilde{y}$

3 I 1 T

then 4 I 1 4

TI 1 T

6 $\tilde{y}$ I 1 6 $\tilde{y}$

1 $\tilde{y}$ I 1 1 $\tilde{y}$

n I 1 n (n from 8 to 24)

25 $\tilde{y}$ 1 25 $\tilde{y}$

26 $\tilde{y}$ 1 26 $\tilde{y}$

27 $\tilde{y}$ 1 27

But the notion of Taofel Field is not stable; sometimes we will detect

28 I 1 28, or we won't detect anything like that, other times we won't be able to predict anything

after 26 I 1 26 . We say that this notion of C. of T. is unstable. She flees.

Thus, we will designate this escape by where ∞ is the infinity sign used in mathematics.

The C. de T. are eifs; their escape ∞ I 1 ∞ also.

5) Consequences

The eifs, those which were placed in the class named EFF, grew by those of class C. of T. and their escape. And all this - as we pointed out in

the 1st level course - because we have not implicitly assumed that the Discrete, continuous, E and M spectra do not contain all the eifs.

Since we had not set any restrictions, during the experiments - types shape overlaps, Sprink device and other montages - other eifs have implementations which turn out to have interesting properties.

Especially for the benefit of living beings, C. de T. are superior to some eifs of the EFF class. And their escape is even better. We can therefore place in dwellings of the generating forms of these high C. de T. eifs and even their escape.

About a Sprink device, with 50 kV of voltage and 1 mA, we get both first C. de T. either

1 I 1 1

2 I 1 2y

We have made such a device. If the voltage increases, we go to C. of T. more students.

We were able to use 120 kV and 1 mA, this allows to go to 3 I 1 3 .

With 180 kV and 50 pA - almost no current is needed - Léon and Marie-Thérèse

Sprink had to go up to 6 I 1 6 and even 7 I 1 7.

Projects are rated at much higher voltages, requiring

very large frames so as not to have flashes and to remain only with effluvia.

At the point of intersection of the lines joining the diagonal points of the spark gaps we detects a shift when the device is energized, which means that a leak of the landmarks present themselves. So approaching this point, the usual physics is no longer usable ; it is necessary to use the physics known as "Unstable Benchmarks".

“Our wishes are the presentiments of the faculties which
lie within us, harbingers of what we
will be in a completed state. » * The

Johann Wolfgang Goethe

* born in Frankfurt am Maine. 1749-1832?

Goethe is among the powerful figures of the West. By the extent and variety of his knowledge, by his gifts as a poet, novelist, playwright, critic, scholar and even administrator, he is in line with the great men of the Renaissance. He always submitted to the laws of Nature applied to the sensible world, without however neglecting these mysterious forces which he classified under the name of “demonic”.

He deserved this eulogy from Napoleon, after their interview at Erfurt: “Here is a man”!

We also owe him his theory of colors and a spectrum that is not that of Newton. We see magenta appear in this spectrum of Goethe which Goethe himself called “peach blossom color”.

It was discovered by J. Ravatin an eif, the “Creative Word” (VC) which is precisely emitted by peach blossoms and by the color magenta.

Note that most acrylic paints sold on the market with the mention “magenta” do not emit VC.

From the therapeutic point of view, it is ingenious to use the two spectra, Newton's and Goethe's, simultaneously.

Exercise: We consider a bottle of Champagne that we fill about 1/4 or to 1/3 of its height of coarse salt.

1) We don't clog it

Check that it sends 2 1----- 1 2

3 I----- 1 T

2) We place a cork

Check that it no longer emits anything.

3) We put it in the ground: we plant in it a copper or elderberry stem, which touches the salt and comes out of the ground.

Check that we no longer detect C. de T. but that above the stem we detects V'm and Vím•

4) We take 2 such bottles of Champagne all containing salt as before and placed in the ground. They are connected by a rod <§ elderberry or copper which are in the open air.

Check that we detect 3 1-----1 3

4 1ÿ H 4

ÿ1 5 3 5

N I----- 1 N for N from 6 to 22.

5) Check that with even bigger bottles it works the same way.

6) If, on the contrary, we try the experiment with small diameter bottles, this works less well or even does not work at all.

SHAPES AND ELECTRIC FIELDS - Léon and Marie-Thérèse Sprink

(continued from the 21st booklet)

It is especially on the instances of MT Sprink who relies as much on his intuitions as on his knowledge, that they themselves realized a device inspired by this remark - The eclipse of the sun of 1913 seen by Léon Sprink in Russia-..

It consisted of four electrodes, arranged around a circumference and connected to a stable high voltage electrical source; however, the results have proved to be incredibly violent and often contrary to the desired result. They called it their "little sun". It was quite by chance that they were able to realize that the phenomenon they observed was very similar to those caused by the activity of the sun. It was MT Sprink who had the joy of seeing it; it was the unforeseen occasion, and for good reason, of the aurora borealis on the night of January 25, 1938.

This aurora borealis covered all of Europe. She was a grand beauty. It has been seen in France but also in almost all European countries, as far as Portugal, northern Italy, Greece, and with exceptional intensity. In France, the Jura, the north of the country, the western provinces, Normandy, Anjou have been particularly favored by this majestic phenomenon, so rare in our regions, and as far as Provence where the astronomer of Kerolya saw her in Forcalquier.s

Gabnelle Camille Flammarion wrote an article in l'illustration [1], We reproduce her description of the phenomenon.

"However, more than two hours after sunset, the clouds are breaking up. Around 6:30 p.m. the northern horizon lights up, as if the day was about to be reborn. It is a nocturnal dawn whose light comes from the North. A blue-greenish glow invades the north and travels northwest. Gradually, the northern horizon flares up. A kind of purple cloud appears in the northeast and moves towards the northwest. It folds up, undulates, expands, dies out, revives, while immense jets, whose color changes from blood-red to orange-red and yellow, soar towards the zenith. The apotheosis occurred around 7.50 p.m. A magnetic disturbance was recorded by Perrotez, at Juvisy: it began on the 26th at 3 a.m.; the violence was such that the light spot left the field of the recording paper for more than an hour".

It is even reported that this aurora was seen, even further south of Europe, from a ship passing off the coast of the Rio de Oro, that is to say at a latitude of 28° [2], " When the sun reappeared, there was nothing abnormal, apparently on its surface . However, a round spot, of a particularly intense blackness had just passed through the central meridian of the star". By testing the phenomenon, we find that there was appearance of a shift. There were the issues of the first 4 C. de T..

On the other hand, a sunspot corresponds to a decalar. Some may be anti-decals but they are not channels. There are no emissions at high C. de T. from these spots.

The decalar associated with the aurora borealis is not necessarily that of a sunspot. The aurora borealis is not associated with a decalar in general, nor with emissions at high C. de T..

There was a very interesting effect reported by L. and MT Sprink while working with their device.

Their device was placed near a heating boiler; during the aurora borealis the boiler had its water boiling although the air inlet shut off worked perfectly. The next day, L. Sprink learned that several central heating boilers had been damaged and that chimneys had burst in the town where he was. In 1949, 11 told Cotton2 about it . Cotton sends him a little-known text by Buffon on observations relating to blast furnaces.

In the 18th century, the aurora borealis were frequent over France and the masterful observations reported by Buffon are in all respects equivalent to those observed by L. Sprink.

L. Sprink also cites Weyprocht's observations of the aurora borealis during Tegetheff's expedition to François-Joseph Land. It was noted, during this expedition, that during certain very mobile aurora borealis, the magnetic needle moved towards the east, that the horizontal component decreased and that the vertical intensity increased! However, this is what L. and MT Sprink were able to verify on their device in January 1938 (except for the horizontal component of the earth's magnetic field because they

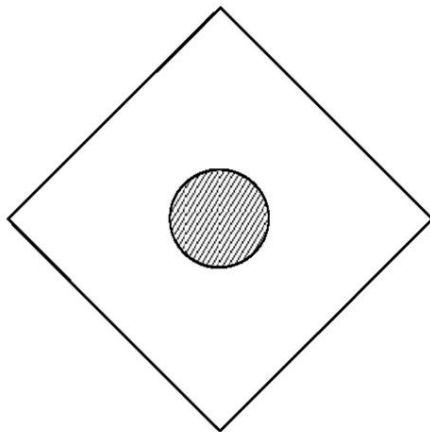

1 This documentation was provided by Jean-François Boédec.

2 Mr and Mrs Cotton have produced a precision balance that bears their name.

did not have a suitable device). The Sprinks had concluded that the field emitted by their device was identical to that emitted at the time of the aurora borealis phenomenon.

In reality, in the case of that of January 1938, we can see that there was the C. de T. which came out of the Sprink assembly but that there were 3 others in addition. On the other hand, the Sprink device makes it possible to obtain a decalaire. L. Sprink also points out that at the observatory of Arosa, it has been observed that the "clear nights" return periodically and always after the maxima and before the minima of solar activity. We have not checked whether this luminescence of the night sky is interpretable in the same way as the aurora borealis, ie whether there is a shift and emissions at high C. de T.. It should be remembered that all the aurora borealis do not have the characteristics of that of 1938 [3], Let us point out a curious observation which occurred in 1913 [4], It was observed from a boat on January 21 19133 .

This is a square halo around the moon. The color of the halo was yellowish. It looked like this: the length of the side of the square was about 3 times the diameter of the moon.

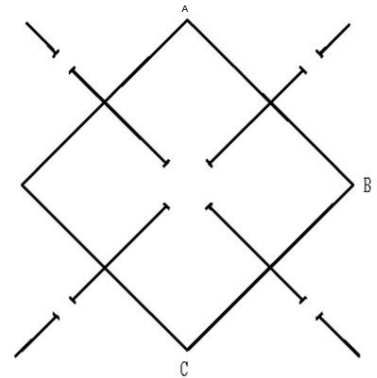

This was not known to the Sprinks, but it is interesting to quote this unusual figure and also to notice this position of the square halo which is found somewhat in this form in one of the assemblies used by the Sprinks4 .

They actually made a square frame put in the position below. This frame was placed on a support. In the middle of the sides and perpendicularly were fixed electrodes which made a cross of Saint Andrew with respect to the horizontal plane. There is a resemblance between the two 2 figures If we consider the shape

composed of the moon and this halo, we see that it was a form neither testable nor intestable.

But we can make it

testable. There are no Taofel fields or decalaire. We see that the programs are not the same but it is good to point out this oddity which is roughly what the Sprinks had made in one of their montages.

Human history is full of these observations which do not seem to fall within the standards usually accepted: we can also cite that of June 15, 1965 where we saw from the deck of a boat, and this was photographed, two suns in the sky almost perfectly. The passengers were on the deck of the ship. They saw the sun and the false sun; the false sun had a little lower luminosity, its diameter was slightly smaller, it was at the same height above the horizon, that is $1^{\circ}8'$ of arc, and its distance from the sun was $3^{\circ}36'$ to the left of the true sun. The phenomenon has disappeared.

If we test, we find the first 7 Taofel Fields.

The false sun emerges from a decalaire. There is no magic state of any type. Do not believe that every bizarre phenomenon has a magic state. A magic state always corresponds to an inconsistency with respect to a human being, an inconsistency due to the fact that a problem is poorly considered.

A phenomenon like a form can very well only be an emergence and then there are other impacts in the local. Emergence leads to a "trace" in the room which is confused with the phenomenon itself if it is completely localized. But if it is not completely in the local then there will be some kind of echoes of this phenomenon for the localization. Sprink's work continues. It was not until 1944 that they found in a cement factory (where they were testing the device developed by them in Strasbourg before the 21st World War) truly complete archives, including daily analyzes of continuous production. It goes without saying that this documentation was for them

3 This observation was taken up in the book by William R. Courliss entitled "Hanbook of Unusual Natural Phenomena, Eds. The Source of Book Project, Glen Arm Md. 12057, USA (1977).

4 The first experiments took place with a circular wooden frame and two diametrically opposed electrodes. The frame was sometimes laid horizontally.

of exceptional value. For more than forty years, neither the manufacturing methods nor the construction of the ovens in the factory in question had changed. The coal always came from the same mine; the quarries were of perfect and invariable homogeneity for more than a century as to their composition and their physical state.

They were therefore able to curve the tensile strength of cements from the years 1898 to 1939. They were greatly surprised when they realized that the exceptional maxima corresponded to the years 1911 and 1930.

In the fatty substances industry they had already been able to pinpoint the year 1911. Now they had two points of reference at their disposal, without knowing, however, whether they involved any physical phenomenon whatsoever. The interval of 18 years corresponds to the saros of astronomers. The Chaldeans already knew this period of 18 years and 11 days which approximately regulates the returns of the eclipses. It includes 223 lunations or 19 times the interval of 346.6 days which separates two passages of the sun through the lunar node.

For their research, it was of extreme importance to find by grouping, this period in natural phenomena.

Yet the periodicity of oceanic transgressions offers a typical example of this. They have their maximum every 18 years, with a secondary maximum at the half-period. Curiously, the years 1911 and 1930 are located exactly at the secondary maxima. The Sprinks also found that on these two dates the Wolfers-Wolf number for the sun was three years from its minimum. It was said above that it is very probably above all the coronary phenomena which intervene in the physicochemical balances.

The Sprinks thought that the true concordance of the solar and saros cycles can only occur every 120 years. Oceanographic observations broadly confirm this supposition, but the situation is complicated by the fact that the solar periods have no fixed datum and can vary from 9 to 15 years. It is therefore not surprising that the meetings of the moon and the sun, the latter being in a determined state, occur only in an apparently random way, but each time they occur, the manifestations of these meetings take extraordinary magnitude. The fisheries chronicles provide impressive examples of this, describing not only monster tides, but miraculous catches as well. As soon as the action of the sun was no longer in doubt, it was normal to return to the annual variations of the results obtained in the factories. It is here that the curves of the monthly averages of the resistances of cements for the periods from 1899 to 1917 have been invaluable.

The choice of this period was determined for two reasons:

- 1) During this period of time, the laboratory premises have not been changed or remodeled and the working methods have remained the same; it was therefore reasonable to think that these factors were not involved.
- 2) This period is sufficiently long so that, on the averages, the variations due to large periods are cancelled.

For the clarity of the exposition which will follow, it is necessary to open a parenthesis. For a long time the hardening of cement had been considered either as a colloidal process or as a crystallization. The two points of view had their partisans and the theories of Le Châtelier and Michaelis shared the favors of the specialists. It must be admitted that in these quarrels nationalism did not lose its rights. Admittedly, both were somewhat right. Indeed, when it sets, the cement behaves like a colloid; it is only then that crystallization, if you prefer, "devitrification" takes place. We will see later that by their behavior in the face of external conditions, cements fully justify this point of view.

To observe these behaviors, the Sprinks were well placed, having had the opportunity to study in stearinization and the variations of processes of a colloidal nature and those which depended only on crystallizations.

By superimposing a cement resistance curve on the solar actinometric curve, the Sprinks found that the two curves are inverse to each other.

After a certain number of remarks which we will pass over, the Sprinks, by reconsidering the results obtained at the stearineries, had come to the conclusion that the yields of limestone followed the same curve as the hardening of cements. In 1932, they had noticed that the curve of yields at the presses and that of the variation of the vertical component of microseismic movements (in the plain of Alsace) were identical. At the Strasbourg factory, they had even tried to reproduce these small earthquakes, without obtaining any effect. Which is normal because causing ground shaking by explosives, or other means, has nothing to do with a real

earthquake which has much more the character of a localization. In a natural earthquake, there are often eifs that appear.

A coincidence put the Sprinks on the trail of the real solution of the problem. One day, the Strasbourg factory had an extraordinary output at the presses. L. Sprink immediately telephoned the University's Institute of Geophysics to find out if there was increased microseismic activity. The answer was given to him that there was nothing! absolutely nothing... ! But the following night, he was awakened by sinister creaks and strange noises and his bed rocked. It was indeed a clearly characterized earthquake. The epicenter was in the Palitinate, near Stuttgart, where the damage was quite extensive and the church bells rang from the shaking. It was therefore concluded that there was some immediate relation between the preceding phenomena, the earthquakes and their yields at the presses.

We know that the warning signs of earthquakes exist. The behavior of animals, horses, dogs, birds and others before an earthquake is well known.

About some earthquakes, we can detect eifs 4 hours to 6 hours (and even 12 hours) before the shaking occurs. These are Taofel fields. These are certainly felt by the animals. Even human beings are able to sense the earthquake.

Indeed in Persia, in Armenia, in the North of the Caucasus, certain natives of these regions feel a vague uneasiness that a long experience has taught them to relate to an imminent earthquake. Animals and humans may feel the Taofel Fields but there is a feeling that is due to something else. Everything happens as if something foreign is coming into our universe and to which some people and animals are sensitive. This something is presented as an "unfolding" which allows the setting up of the usual field of coherence, which will make it possible to find the turbulences of the earth's crust, etc.

Let's open a parenthesis on the prediction of earthquakes, (naturally it will be a question here of the usual point of view of earthquakes).

For this, consider the case of China, which has been hard hit by these disasters. It was in China that the deadliest earthquake of all time took place, that of Hushsien, in Chen-si, which killed around 820,000 people in 1956. There were many others and the one that struck Hsingtai in Ho-pei in 1966 led Prime Minister Chan-En-Lai to give seismology priority.

Today, China has 10,000 professional seismologists and 100,000 amateurs working in an organization comprising 17 centers and nearly 300 regional stations. By enlisting volunteer observers (peasants, workers, teachers, telephone repairers, meteorologists, radio personnel) the Chinese wanted the ordinary citizen to be on the side of the scientist. They enjoyed trying to predict earthquakes.

At first suspicion fell on the province of Leao-nmg. The specialists noted that the epicentres of the small tremors following another earthquake, that of Hsingtai, seemed to move towards the region of Leao-nmg, a highly populated industrial region. In 1970 it was decided to start monitoring this province very carefully. All the existing techniques in the arsenal of seismology were implemented, starting with the study of past earthquakes and local geodesy.

The geodetic study of a major fault, made from September 1973 to June 1974, showed that the surface of the ground there rose twenty times faster than in normal times and inclined towards the northwest. During the same period, a change in the local magnetic field was recorded and the tide observation stations on the coasts of Leao-tong Bay noted a rise in sea level.

In 1974 there were five times more small earthquakes in Leao-ming than in previous years.

All this led the government to warn the population that a dangerous earthquake was brewing. However, no one could yet say when it would take place. Other symptoms were therefore sought, for example changes in the behavior of the animals.

Two hours before the earthquakes that took place in Po-hai on July 18, 1969, a guard at the T'ien tsien Zoo noticed that the tigers were behaving strangely; He warned the seismologists of the place and signaled that a great earthquake might well be approaching. In the province of SeuTch'ouan, in September 1972, a forecasting team was able to announce the outbreak of another earthquake after observing "the panic of chickens, pigs refusing to enter their piggens, horses and sheep frantically running in all directions. For the Chinese, men in the streets and in the fields can provide valuable information, whether on the behavior of animals or on the level of groundwater.

Precisely such symptoms were observed in Leao-nmg in December 1974. In four communes, the water in the wells became muddy; bubbles burst there on the surface. Rats and mice abandoned their

holes, just like the wintering snakes that You saw hovering on the ice. An earthquake then occurred seventeen kilometers from Hai-ch'eng, leading authorities to believe that a larger tremor was in preparation⁵.

This case is interesting because, although there may have been emissions already appearing on that date, and disappearing shortly after to reappear a few hours before the earthquake, it seems that the localization is felt well before the earthquake . .

At the beginning of February, the animals continued to behave abnormally, and the wells began to show other symptoms of disorder: twenty-two became artesian. The opposite was observed in a hot springs station: three times the outflow of water was interrupted. According to the report, the most remarkable event took place in Chaozihe commune: Yu-nan province, where water and gas wells were seen to spring from the ice like geysers.

The pace of events quickened. On February 2, a seismological station recorded a sudden drop in ground electricity; another observed that the tilt of the ground was moving towards the southwest. All of these remarks made it possible to avoid a catastrophe: on February 4, 1975 at 7:36 p.m., the earthquake of Hai-ch'eng had a good time, but most of the inhabitants, warned, had been able to leave their houses and the animals had also been taken out.

Other disasters that are not earthquakes have also been perceived by animals. It is well known in France that the landslide which occurred at night on the hill of Fourvière in Lyon around the 1900s was sensed by the horses which the night before did not want to enter their stables. There too, perhaps some eifs could have been felt by the animals, but something else, which is a contribution to our localized world, is felt. There is localized physics instability and gas bubbles, mud in the waters, geysers on the ice etc. are its manifestations.

Thus, all these phenomena with quite catastrophic effects seem to be only a localized view of a deeper effect because it is not localized; it's almost an attempt at localization.

To a form like the planet earth are associated many other forms which are not localized; who cannot be located. They are in a channel. But they can have localization tendencies. There are also "echoes" to the forms.

These other forms are not in our field of coherence. In the case of animals either they project another field of coherence which gives them access to another reality, or they feel the disturbance of their field of coherence. One can wonder if one is in a localization or in the disturbance of a field of coherence by another field of coherence in the case of an earthquake.

The Cartesian interpretation of these phenomena is an unfolding in the room on which causes and effects overlap.

Let us mention a device known since the highest antiquity and called "wind harp"^{6 7}. During numerous observations, we have been able to realize that the lowest sounds of these instruments precede the rain by a few days and that the highest sounds precede the rain by a few hours. As a result of these observations, special instruments called "meteorological harps" were even built. Here is the description given by a chronicle of the time, of a harp built in 1789 by Ventan, provost of Burkly, near Basel in Switzerland.

"This harp consisted of 15 iron wires 320 feet long, placed in a garden, 2 or 3 inches apart, and stretched with large cylinders. The thinnest rope was about a line thick, the strongest 6 lines. They were arranged in the direction from north to south, and inclined so as to form an angle of 20 to 30° with the horizon. When the weather changed, the harp gave out sounds so powerful that they drowned out all the noises in the house and almost inspired a feeling of terror; sometimes its tremors mimicked the rapid murmurs of boiling water; other times the distant playing of a harmonica, a chime or an organ. Attempts were made to stretch these iron cords in the direction from east to west; they no longer produce any effect. » [5]

⁵ "The UNESCO Courier, May 1976 (XXIX year).

⁶ L. Spnnk was aware of this experience and mentioned it in his report.

⁷ We mention it here because 11 must be careful not to model the effects of delocalization relating to earthquakes on meteorological harps.

More recent results say that the wires must be stretched in the direction perpendicular to that of approach of the disturbance not yet sensitive and that on the other hand, 11 would have been found that on two lines stretched perpendicular to each other There is always only one that reacts.

The remark about the wires stretched in the direction perpendicular to the direction of displacement of the disturbance is vague because the harp is not symmetrical because of the different diameter of each string; then it seems that the harp oriented in a well determined direction, that of the North of Form (if it is quite isolated in nature) must then give the most powerful effect.

This meteorological harp also expresses an effect in the process of localization. At the time of the songs it emits, there are fields of Taofel which are present. That is to say that we are faced with a phenomenon where the local is deformed but there is no substitution therefore no appearance of OF as a support. This harp is a localized form but still has an Ext.

In the case of earthquakes, we have shifts in the terrestrial globe, not measurable in position since the landmarks are on the run, but through these shifts other landmarks are formed and these are modeled on the pressure forces, them, localized and on other parameters. It turns out that the earthquake is caused by a form that cannot be located. This form happens to exist through a localized structure or something else. The localized structure may be a disappearance of rocks with pressures or something else. In the case of the meteorological harp, it is not a form which is not localizable which intervenes. She is a completely localized form that has an Ext. A fleeing form uses the local to realize itself, but as its name suggests, it is made up of fleeing pieces; these cannot be indexed by a sequence of integers. There appears a shift in the numeration. A fleeing form relocates. In the case of the weather harp, there is additionally a channel.

L. and MT Sprink immersed themselves in the work of V. Bjerknes [6] and noticed that this physicist noted before the First World War the formal equivalence between an electrodynamic field and a hydrodynamic field. V. Bjerkness used this equivalence in his calculations of "hydrodynamics" without drawing any other conclusions. However, it was only after the Second World War, and faced with the fact that the speed of the advancement of solar prominences increased during eruptions, and that this acceleration seemed to be due to a mysterious and unknown force, that we began to glimpse the extraordinary significance of this analogy. At the current stage of research, we are still at the simple observation of the existence of the hydrodynamic fields of Bjerkness. V. Bjerknes wrote [6](in volume 1, p. 25) "we must indeed regard as a secret of nature, the scope of which we are still very far from knowing, the deep analogies of the hydrodynamic field and the hydrodynamic field electricity and, likewise, with the magnetic field. There must be between the two series of phenomena a relationship little known today for a system of fluids as general (permanent hydrodynamic field) as the one we have considered, can move only in accordance with the formulas electrostatic and magnetic". Further "We will leave aside the possible significance of these analogies from the physical and philosophical points of view. We only look at objective facts which in practice have considerable significance. The equations of hydrodynamics make it possible to use the same results, the same methods and the same modes of intuitive representation in very different fields of physics".

This analogy was limited to the study of solar prominences.

The Sprinks considered it reasonable to admit the existence of analogous fields also on the terrestrial globe and to seek there the cause remained mysterious of the phenomenon which will be described hereafter.

It is not known whether L. Sprink tried to explain earthquakes by this analogy between fields.

Nevertheless the concepts we are developing were not known to Sprink and they tried to express them in the usual language although they felt that they were facing something else...

Let's see their study on the structuring of stones. The Sprinks, during their experiments, removed fired blocks from lime kilns with a geometric spatial structuring that did not exist before firing. Naturally, their device operated near the ovens and these observations were only observed during the operation of the device.

They were able to observe two types of structuring: one in rods (generally sections in pentagon or hexagon, kind of basaltic structuring "in organs", the other in "honeycombs" (kind of structured terrain of the Tundra) The first is identical to that of band clouds, the second to that of "lacunar" clouds. The structures have been reproduced in laboratories with smoke. The aerodynamic conditions necessary and sufficient for their formation are clearly

known.

J. Coulomb and J. Loisel have given a description of convection phenomena which make it possible to establish certain equivalences between clouds with a "lunar structure" and the structured stones of L. and MT Sprink. Let's see what J. Coulomb and J. Loisel say.

"As early as 1900, Bénard had studied experimentally, in an almost definitive way, the convective vibrations in a layer of viscous liquid, uniformly heated from above. The layer breaks up into prismatic cells of roughly uniform dimensions, in the center of which the liquid rises to descend again along the walls. Bénard gave this organization the name of "cellular vortices". In steady state, the cells are almost regular hexagons. If the liquid is made to flow on a hot plate (terada) the cells are replaced by rollers parallel to the lines of slopes which are called "band vortices".

"The theory of "thermoconvective" circulations in viscous liquids was initiated by Rayleigh, starting from Boussinesq's equations, and perfected among others by Jeffreys".

Attempts to verify Rayleigh's theory have generally given fairly good results. The checks can relate to the minimum transverse dimensions of the stable cells and also to the importance of the heating necessary for start-up. In fact, for moderate heating, if the liquid's calorific viscosity and conductivity are high enough, a particle moving under the action of a difference in density would do so so slowly that it would have time to settle. temperature equilibrium with its surroundings before having traveled an appreciable path, and thus canceling out this difference in density. The particle thus does not move appreciably, and one then obtains a curious stable preventive state. In support, excessive heating would lead to the sudden replacement of cellular movement by disorganized turbulent movement, but the theory does not yet provide for this latter phenomenon.

»

"Convective circulations in air are much less well known than circulations in liquids. »

The Sprinks, in addition to the structuring mentioned above, had often found in their samples taken from the ovens, stones with a radiated structuring. Contrary to what is observed on oolites with radiated structure, here the rays are not in general straight lines, but are curved parabolically and one does not find in the center of the geometric system the slightest trace of a crystal or of a fossil. This spatial structuring is due, for the Sprinks, to the existence of an auxiliary electric field, out of connection with the stone itself and to the polarization of the particles electrified by this field. This structure is reminiscent, as L. Sprink points out, of that of the debris of a racing car that fell in 1947 in Sikhote-Alinsk, in Siberia. This was also the first time that we encountered such a structure for a meteor.

In the case of the "Pierres de tonnerre" of the chalk of champagne and of the oolites with radiated structure of Cettigien of the Ardèche, it seems that there is a field which structures the stone but the starting point of this field is localized by the debris of a crystal or a fossil. This fossil can be whole as is often the case in Champagne.

L. Sprink made a very interesting point about stones with a "honeycomb" structure. He had been struck by the resemblance of their appearance to that of the surface of the moon. He says: "For stones, the origin of these craters is beyond doubt: it is due to stationary vortices, generated by mass transverse vibrations".

"It would be quite plausible to assume that the craters of the moon are not due to meteoric bombardments, because the structures of the lunar surface offer disturbing analogies, smon a complete identity with the structural shears which determine the flaking of the surfaces of our stones. It seems likely to us that the formation of sunspots with their powerful magnetic fields goes back to analogous causes, that is to say standing waves, generating more or less stable vortices of electrified matter. As for the origin of these waves (in the last two demonstrations) we have for the moment the least clue Naturally L. Sprink did not know that his device emitted eifs at the EFF level and the

Taofel Field 1 I-----1 1 . When such a Taofel Field is detected from the decalaire which is at the point of intersection of 2 discharges in a cross between the spark gaps (which only happened very rarely in the case of the assembly of Sprinkles since they did not know the optimal conditions for the success of the

phenomenon) privileged zones appear in the space surrounding the device, which are like weakened echoes of the decalare. They constitute a localization neighborhood⁸. The decalare and all of these zones behave like "a fleeing form".⁹

In the case of the structured pebbles of L. and MT Sprink, there is a disturbing fact at first sight, it seems that the ores behave as if they were plastic and yet in the furnaces at the temperature of 1100 to 1200°, they are certainly not and keep their primitive forms. The same phenomenon is found in nature for oolithes and modules which interpenetrate without any mechanical deformation. Here is what M. Cayenne, who has extensively studied the plasticity of oolithes, has to say:

"Impression deformation has long been reported and repeatedly invoked to demonstrate the plasticity of oolites. Juxtaposed oolites penetrate more or less deeply into each other, like "impressed pebbles". If we come to separate them, their surface is hollowed out with small cupules, giving the measure of the impression".

"The phenomenon does not involve any difference in relative duration, because an individual who sinks into a neighboring oolite is in turn impressed by another oolite. The deformation occurs without breakage of the sheets, thus testifying to a certain plasticity of the material. In my opinion, this matter of plasticity does not necessarily evoke that of soft matter, and this is so true that we have only ever observed oolites in the process of formation on the edge of the reefs and on the shores of the Salt Lake. are soft.

Furthermore, I have noted many examples of ferruginous oolites deeply set in the debris of molluscs that we do not imagine to be plastic at all" [7],

The plasticity of rocks and crystals is well known. It is well known that, without the action of a continuous and immutably directed force, any solid deforms slowly. What surprised the Sprinks in their structured stones was the speed with which these structures appeared, and the fact that the sheet structure of the limestone remains without influence on the structuring. These two structures interpenetrate without destroying each other. They could not give any explanation to this phenomenon but the observations of Mr. Cayeux confirmed the existence of analogous facts.

L.Sprink thought of hydrodynamics to explain such phenomena and he sought that it could be the nature of the wave capable of giving similar vortices in very viscous media; it is a transverse wave. he had first thought with his wife of an electromagnetic wave.

Hence if we follow his approach, the first field of Taoefel (since it is about him), behaves like an electromagnetic wave. And we fall back into the points of view of Bélizal-Chaumery of before the last war, who also thought of electromagnetic waves for the Emissions due to the Forms. This point of view was followed by J.de La Foye and others a few years ago. Can we axiomatize the existence of transverse waves which are not of known nature? what we call the eifs at the EFF level and the Taofel Fields? We cannot speak of these localized notions because we use a language and representations where we try as much as possible to escape localization. of the ovens, the Sprinks were able to discern three different structures.

The "honeycomb" structure: the imprints are generally in the planes parallel to the planes of the rock deposits and are arranged in almost parallel rows, which thus gave a very clear image of the elastic vibrations of a solid under the influence of a transverse wave. And if we express ourselves in the language of vibrations, we would have to make lines of hyperbolic currents.

The structure of stones which peel like an onion; especially in the kidneys of the limestone: what is remarkable is that whatever the origin of the kidney, we always obtain the same thickness of the peels. the starting point used by L.Sprink for the calculation of the acting wavelength. In the language of vibrations we would be dealing with elliptical current lines.

The structuring in rods, the length of which can reach several tens of centimeters.

Mathematically, it should be possible to achieve this structuring for the two preceding cases, on condition that the limits of the two opposite cases of a vibrating cell are rejected ad infinitum. Obviously this is only possible in the direction parallel to that of the layers of the deposits, otherwise there are structural discontinuities and reflective surfaces. Bherknes pointed it out that way. Except the structuring in honeycombs, one can with the two others by natural way, although in a completely exceptional way. Gold,

⁸ Location neighborhood or voiloc.

⁹ The fleeing form is partly delocalized: we can say that its localization contains its delocalization.

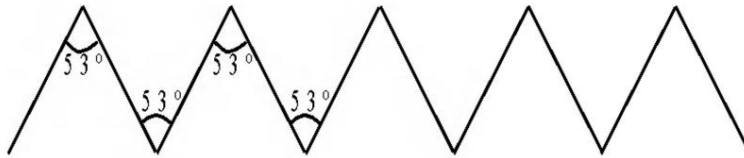

© EÜRECALL

with their devices, in operation, the Sprinks had them regularly; but naturally, let us remember, the correct operation of their device was only obtained after long start-up times, and when they cut off the high voltage, there was a very long recovery time after this high voltage had been established. In conclusion, we detect with the phenomenon mentioned above on stones a

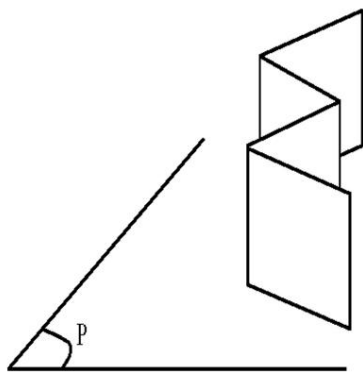

shift and the C. of T. 1 I-----1 1

Exercise: We give ourselves a dihedron with an angle of 53° - we will realize it by 2 rectangles of cardboard, identical, glued by the longest side (height of this edge: 40 cm) -

A "screen" is produced with such dihedral angles of 53° .

On les place sur une table sans tiroir P

1) Show that in a close neighborhood of this shape, we detect the C. of T.

$$1 \quad | \quad 1 \quad T$$

$$2 \quad | \quad 1 \quad 2 \bar{y}$$

$$3 \quad | \quad 1 \quad T$$

$$7 \quad | \quad 1 \quad 7$$

2) Check that if the table has drawers, in general the screen shape only emits eifs at EFF level.

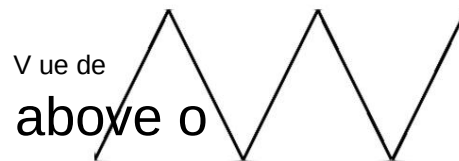

Remark :

If we take a representation $R!$ such that we consider that the only possible eifs are those of the EFF spectrum , then only some of these eifs will be detected. of the EFF spectrum

If we take a representation $R2$ - which is ours - as we have considered other possibilities then we detect C. of T..

We can then consider $R!$ as subtending $R2$ and placing from that structures in $R!$ and $R2$.

3) We place a solid or hollow ball with a diameter of 8 to 10 cm. in dihedra

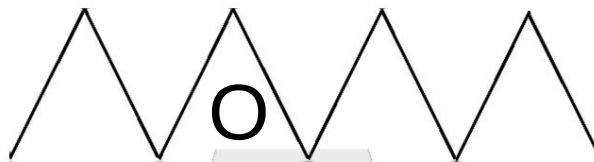

Check that we obtain the C. de T.

3 I-----1 T

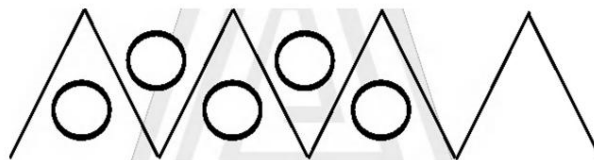

ÿ1 4 H 4

ÿ1 5 H 5

I. **Forms and electric fields - Works of Léon and Marie**

Therese Sprink

In an attempt to determine the nature of these famous emissions, the Sprinks made laborious tests from the years 1951 to 1953 and they had added to their device (comprising an octagonal frame, spark gaps, stabilized high voltage, frame support), a magnetic field variable and this in 1952. The frequency of the magnetic field was not very high: two megacycles at the **most**. Some sort of resonance seemed to occur with certain frequencies of the magnetic field. The resonant frequencies formed a discrete 1-2-3 series... They concluded that their device was both an amplifier and an acoustic resonator. Here we have analogies with usual devices; this is also what is found when using a fairly cylindrical tree trunk of radius r ; one can find a propagation of the eifs which resembles a kind of rectilinear optics, with however different laws (propagation between the circle of radius r and the coplanar and concentric circle of radius $2r$) [1].

Naturally this analogy was reinforced by remarks made by L. Sprink, such as the following: acoustic resonators (a Helmholtz sphere or the pots of Romanesque churches) only respond to the vibrations of the notes for which they have been tuned, while a electromagnetic resonator only responds a little better to the frequency which is its own.

But L. Sprink says "our device is not an autonomous transmitter, but a resonator whose exciter is elsewhere. He also makes a distinction according to whether he used the low frequencies of the magnetic field (up to 25,000 cycles/s) where he says that then it is the acoustic resonance whereas between the 2 we would have a mixture of 2 types of resonances. Above 100,000 cycles/s, he noticed that he had waves of a hydrodynamic nature.

Let us not forget, L. Sprink only saw the world in its localized presentation despite that "his approach was to assemble whereas the usual scientific approach is to divide" Einstein had told him during a visit that L.

Sprink had returned it to him before Einstein's departure from Germany.

But the Sprinks had become very aware, despite the fact that they thought of resonances that the effects, especially in vertical furnaces, could not be attributed to electrostatic fields because an electrostatic field due to a partially localized charge could not have a range equal to that which they had observed on rows of kilns several tens of meters apart and this, without the effect being weakened. Because we know that the electrostatic field decreases as the square of the distance. In addition, the effects on the lined ovens were not felt, in time, not in order of distance from the source but the first oven was packed and then the third, the fourth, then the second etc ... and this repeated in this order after switching off the device and returning the high voltage. Thus, thanks to the high frequencies of the magnetic field, they had the assurance of a new phenomenon, the effects of which were like hydrodynamic waves.

They measured the thickness of the "peels" of structured stones in the case of elliptical currents and this gave them a wavelength (if they assumed they were dealing with "mass" waves) of about 7 mm .

The "meteorological harp", too, can be considered from the point of view of L. Sprink as a resonator whose frequency is audible. The measured wavelength still justifies the name "wave form" given to these emissions, as had been supposed by Chaumery, Belizal and others. It must be admitted that the temptation is great to confuse them with waves. But if we consider that the universe has in it a delocalized existence, we notice that certain notions of the delocalized resemble notions of the localized world.

Let's take this opportunity to say a few more words about ancient harps. They have been little reported by the musicians. A book by Georges Kastner [2] deals in part with the following subjects:

- The harp of Aeolus
- Origin of music
- Origin of the myth of the Harmony of the Spheres
- Sound phenomena, examples taken from the Bible, from Greco-Roman antiquity
- Travel stories
- Echoes
- Harmonies of caves, rocks, waterfalls
- Plant harmony.

We cannot cover all these topics here. Some, like many echoes, are explained in physics by the reflection of sound on walls, but others, like the music of the spheres, are much more difficult to study because they are heard by a few people at certain times; it can also be heard during doublings.

Samuel Franerici had such an experience. L. Sprink seems to have heard this music one night near his camera. Naturally, it does not appear that it was the wind that blew on the spark gaps to produce these sounds, the device being enclosed. We will nevertheless, here, look at these Aeolus harps and so-called meteorological harps.

The origin of the Aeolus harp is not known. "...Legends and even true stories, says Kastner, reveal the existence of natural Aeolus harps, produced by the rustling of foliage, by the friction of reeds and tall grass waving in the breeze. ...". Nature was able to inspire researchers, who used the wind to excite the strings of instruments they made.

Kastner has a slight tendency to reject any attempt at a non-rational approach - which makes him very attached to instruments that work with the wind -.

The Jesuit Father Kircher and shortly before him Jean-Baptiste Porta (Neapolitan born around 1540 approximately) studied treatises by researchers who preceded them on Aeolian harps and trumpets and sound pipes. Similarly, Father Bartoli, also a Jesuit, after Kircher and Porta, studied all these works; an English physicist also, William Jones and later Matthew Young (from Dublin) mathematician treated the harp of Aeolus scientifically. It is obvious that this list is not exhaustive; for more precise details it is good to relate to the work of Kichner and certainly that anonymous researchers also obtained results; often on the death of the researcher, the writings and apparatus are put back in attics and after several moves end up in the fire or in the trash and we have even seen in some cases that the families, upon the death of the brilliant discoverer, hurry to destroy everything because of fear of witchcraft which could have interfered in these works. Under the pretext of prudence and prudery, it is an attitude of profound stupidity.

We have already seen that L. Sprink had knowledge, perhaps through the work of Kastner, of a meteorological harp, that of Ventan, provost of Burkly near Basel.

The meteorological name was given by Father Gattoni who had made a gigantic harp (he called it: meteorological harmonica).

Ventan's was made of 15 metal ropes and guts, attached to the top of a high tower about 85 meters and 150 paces from his house to which he fixed the ropes so as to form an inclined plane.

The instrument first gave results of a pleasant harmony, but soon the agreement was broken by the atmospheric influences and it is then that the inventor of this instrument imagined to make an instrument of meteorological observation thanks to the intonations of the strings resulting from the various states of the atmosphere.

Let us see the remarks of Canon Gattoni:

- 1) It does not matter whether the metal wires are insulated.
- 2) You don't hear the sound quivering when the wind blows violently and shakes the wires, but only when the air is relatively calm.
- 3) No sound is obtained when the wires are less than 10m in length, annealed wires are more favorable.
- 4) The wires produce this same quivering, but less sonorous, when they are stretched with glass supports; it is still less noticeable when they are stretched with silk cords.
They are electrified at the approach of storm clouds, like any insulated metal. However, these sounds cannot be attributed to electricity, as some have wanted to maintain without any foundation, adds the canon (it is a question here of static electricity). Nevertheless adds Bellani (in a footnote reported by Kastner) if it is about dynamic electricity, one can obtain sounds but let us notice in this case there was no dynamic electricity.
- 5) The variation of the state of the atmosphere for Gattoni is the cause of the effects produced by the harmony of the threads: because if the sky is serene or rainy for a long time, no quivering is observed in the threads.
- 6) It is proven that sounds are not produced by accidental causes, such as the impact of birds, insects...
- 7) It is also proven that changes in temperature only affect metal wires by successive expansions or contractions, producing quivers which depend on the relaxation or stretching of the wire.

In summary, it emerges from these remarks of Canon Gattoni, that the meteorological harp is not excited only by the wind as the aeolian harp must be, although certain aeolian harps certainly have characteristics of the meteorological harps, but that the changes of time that must occur are signaled by this instrument. It therefore seems that a change of weather is necessary and that the phenomenon which interests us occurs before the change of weather. It is, for the observer attached to the harp, a forerunner.

It appears from the high-field eifs of Taofel. We are going to find ourselves with a partially delocalized process which is localized. Note that these meteorological harps have an ext (a harp usually does not; moreover, a harp does not emit Taofel fields except for certain very specific compositions). Could a variation in atmospheric pressure initiate the phenomenon of the singing of the strings? It is not impossible. But it is interesting to think back to the noises reminiscent of those of jets of pressurized steam which were heard near the Keely bottles [3] (the noises are different in sound from the weather harps but can be related to them by the relocation phenomenon). If we consider the occultist point of view, we can relate these phenomena to the "ether of sounds". This ether is in reality the Aether of which L. Boutard speaks [4]. The alchemists also speak of "the ether of heat"; they distinguish several "ethers" [5]. This corresponds to their unexpressed sensations, and very vague for most of them (vague in the sense that the concept of ether for them was isolated, not attached to a field of consistency).

The aether can contain the small snakes of which L. Boutard speaks but also more elaborate notions. The little snakes are only the result of a projection of a fundamental structure as for the usual field of coherence, the atoms, and fundamental particles are the result of a search for the materials of assemblies of the

EUREK'ALL

matter. The sounds that came out of the bottles associated with Keely's engine, such as those of the meteorological harps, David's Harp, are on the same level as the production of glycerine, colors, peptides etc. which come out of the generator in the form of Boutard's rhombe. It is the same, moreover, with the music of the spheres, which is a localization. At times, which L. Sprrnk could not control and very rarely, at night, his camera played the role of L. Boutard's rhombus [4]. The music of the spheres can also be heard during a duplication; it is the one that doubles which is the equivalent of the device with a rhombus; it is the state obtained by duplication which gives this possibility but certain individuals can hear it while looking at the starry sky, on a summer evening, in an atmosphere of solitude² [3],

² S. Franeric actually heard the music of the spheres under such conditions.

"Error does not become truth
because it spreads and multiplies.
The truth does not become error
because no one sees it. »

Gandhi * The

Gandhi (Mohandas Karamchand, known as the Mahatma, that is to say the great soul) (1867-1948), ascetic and India patriot.

He studied law in Great Britain and then settled in South Africa in 1893. He endeavored to improve the lot of his co-religionists who worked in this region. In 1914 he returned to India and agreed to support the policy of the Anglo-Americans in order to obtain the independence of his country. Britain not having kept its promise, he preached and applied the principle of non-resistance, of non-participation in all violence, and also of non-participation in the coercion of the courts, taxes, military service of the British administration.

Imprisoned on several occasions, he practiced a hunger strike and thus obtained concessions from the English and also from his compatriots (appeasement of the uprising of 1921); He was devoting himself, with a seventeenth fast, to the fight against the civil war between Hindus and Muslims, which was tearing apart India, which had become independent, when he was assassinated in Delhi on January 30, 1948. He wrote an autobiography: "History of my experiences with the truth" (1925).

EUREK'ALL

On the work of Léon and MT Sprink

Where

Historical report relating
to a set of various devices intended to improve
certain chemical, thermal and metallurgical reactions and whose
purpose is
an energy and financial economy in the future world.

1) Introduction

We present in this report the validity of physical observations and industrial results covering a period of nearly 130 years. All of this work relating to changes in the state of matter began with analyzes and scientific remarks made around 1850 and published in various reports by the Academy of Sciences. Practical applications on various industries were carried out in France from 1920 to 1955 on an experimental basis. Currently, a resumption and continuation of previous developments are considerably strengthened thanks to the technological fallout from the measurement of certain physical fields in space following NASA experiments and astrophysical information collected by Soviet satellites.

In addition, newly experimented effects at the level of emissions, absorption, adsorption, resonances due to forms oriented in space, now make it possible to clarify certain variables or phenomena considered as difficult to reproduce for lack of being able to control the parameters, even by measurements. of classical fine physics.

2) Part 1: Principles of Sprink-Ravatin devices made experimentally in operational models and practical advantages.

- a) Summary of patent no. 1,005,532 issued on December 26, 1951 to Mr Léon Sprink and Mrs née MT Roussel.

"...improvements in some remarkable chemical reactions such as combustion reaction, reduction, hydrogenation, etc. by the use of metal spikes mounted on an insulating support in the form of a frame and connected to the two poles of a high voltage direct current generator..."

Experience proves that such a device put into operation near autoclaves, cement and ore kilns allows reductions in operating time from 24 hours to just 3 hours with a calorie saving of 50% maximum.

- b) Summary of patent no. 966,735 issued on April 8, 1950 to Mr Léon Sprink and Mrs née MT Roussel.

« ... Note that a large number of changes in the states of matter or reactions depend, in addition to the factors conventional pressure temperatures etc., electrical or magnetic phenomena produced nearby from a certain degree of activation of electron discharges crossed and arranged in a determined orientation. ...»

The experiment shows that for reactions such as the clinkering of cements, the decarbonation of lime, the saponifications, the reduction of ores, and during the use of the device near the products to be transformed, we always observe a gain on operating time and on the fuel used.

- c) Patent application no. 78-21083 of July 13, 1978 by Mr. Jacques Ravatin, doctor of science. ESCIL engineer.

Summary: The subject of the invention is an apparatus making it possible to amplify, according to a principle known as "Localization", the effects due to simple geometric shapes by associating them with a device generating electric, magnetic and electromagnetic fields, as well as to a closed polygonal frame with the character of right and left Moebius strips. Are associated with the volume generated by the devices of natural or artificial minerals such as:

- Pyrrargyrite or Argyrythrosis
- Proustite or Red Silver
- Obsidian or volcanic vitreous paste with low water content
- Carborandum or Silicon Carbide: C If

whose amplifying power on the effects obtained has been observed, as well as conferring a so-called "fractal" character (well known in mathematics) to the parameters of the close physical fields.

The practical interest of the variation in the value of close physical fields is directly linked to changes in the state of matter with a considerable acceleration of the chemical and thermal reactions sought for obtaining conventional industrial products or new steel products with a reduction of the energy potential usually required by at least 30%.

The additional advantage of J. Ravatin's device is positively materialized by the instantaneous obtaining of the desired phenomenon(s), whereas with L. Sprink's device the start-up time could sometimes take a few days to several weeks.

3) Part II Different types of observations and experiences that brought patent applicants

L. and MT Sprink have made experimental devices capable of saving time, fuels and obtaining better or new manufactured products.

a) General remark

The observation of certain natural phenomena in physics, chemistry, biology, sometimes allows, by applying a practical analogy, to realize in small what nature does in large or at least to draw a conclusion which will help man in art, industry or science. Thus the knowledge of interstellar radiation in vacuum allowed the realization of radio lamps, the understanding of radioactivity radiation led to the realization of "nuclear" and the sending of electric current in the ground allowed the Schlumberger brothers to build an empire based on the search for oil since 1912.

b) How L. Sprinket brought to be interested in the problems of the Forms, their action and the fields of strength against bacterial or chemical reactions at various temperatures.

Léon Sprink comes from an old Blelo-Russian Baltic family allied to the Tolstoi. Very early on he showed qualities of observation, analysis and realization whose originality challenged him to pragmatism. For example: in his 151st year his father took him to visit a brewery in his native country where it was difficult to obtain, by the processes then known, a beer of mediocre quality which gave a lot of tablature to professional brewers.

Barely returned from this visit, the young L. Sprink imagined a model of tanks whose alloy and especially the forms allowed the accelerated fermentation of the hops, giving a beer of much better quality and more quickly than by the usual artifacts.

In view of the intelligently executed realization of this model and in view of the positive results obtained, his family directed him to the Polytechnic Institute of Saint Petersburg from which he graduated before the First World War.

Around 1913 L. Sprink had the chance to observe an unusual phenomenon of the solar corona during an eclipse. The emissions he observed gave the image of a cross of Saint Andrew outside the halo, which is an extremely rare phenomenon and moreover unexplained at this time.

The main work of observations and attempts to correlate phenomena related to solar plasma, and the aurora borealis were made by Gassendi in 1621. Have done work on the subject in order to "understand" the interlinking of phenomena, Cassini 1686, Halley 1716, De Mairan 1726, Arago 1855, Angot in 1897 etc... a special place goes to Auguste Bravais, author of the theory of networks applied to the intimate structure of crystals who established correlations between these structures by comparing phenomena relating to crystals. halos, parhelia, aphelia and unusual diffractions observable in the Earth's atmosphere.

This French physicist, member of the Academy of Sciences in 1854 tried to connect the close and distant observable effects by similarities such as Sprink will use some later.

It should be specified here that from Gassendi until 1937, the total time of the multiple observations of the solar corona during the eclipses did not exceed a few hours due to the very short time of the possibility of observation of the total eclipse [6],

L. Sprink therefore had not only the possibility of making an exceptional observation but above all the intuition of bringing closer to the vision of these plasma effluvia, the then brand new notions of electricity and propagation of electromagnetic waves (developed by Rhumkorff and Hertz) d a possibility of acting on the level of the ground on the phenomena of combustion and heat by combining especially thermal reactions of the currents of static electricity emitted by a stabilized generator.

At that time, fertile in multiple and primordial discoveries, it turned out that many intuitions could be crowned with success at the level of technological reality, while mathematical theory could only account for the reality of phenomena for a few years. later. This was the case for Sprink's devices in its first trials.

The events of the First World War as well as those of the msse revolution earned L. Sprink an imprisonment in the fortress of Saint Peter and Paul. He came out ALIVE, but remained physically very ill.

He emigrated to France where he married Marie Thérèse Roussel, granddaughter of a famous French geologist.

The couple then worked together on all the theoretical and practical achievements aimed at obtaining new chemical reactions at high temperature, products with new structures, by synthesizing the effects of electric fields supposed to exist in the upper atmosphere with thermal gradients. more or less high obtained by various combustions.

During this period, the Sprinks were in frequent contact with Maurice and Louis de Broglie, the Cottons, the Curies, who understood Sprink's work as the dawning era of all new chemistry, all new physics and the opening towards a fruitful understanding of the true field relationships existing in the solar system.

The Sprinks went to Germany in 1930 and met Einstein at length to explain their work to him.

The conclusion of the latter can be summed up in this sentence: "I try, says Einstein, to analyze the universe and you, you recreate it before our eyes".

c) Fundamental experiences of Sprink and first observations of facts not yet observed by the predecessors: Coulomb, Faraday, Gauss, Whimshurt...

We SAW above how Sprink, according to his observation of a space phenomenon, had connected the new possibilities of carrying out chemical and thermal reactions in association with a stabilized high electrical voltage which one could suppose at the time that this voltage had to exist in interstellar spaces and especially around the sun. It should be noted that the concept of solar electro-jet came only after the discovery of thermo-nuclear reactions and the measurements carried out by rockets and satellites.

L. Sprink therefore carried out a first rudimentary assembly consisting of a very dry circular wooden frame through which were fixed in a cross of Saint Andrew along the diagonals, metallic conductive electrodes themselves connected to a stabilized high voltage generator .

When setting up the assembly on an insulating support, a first remark was made by Sprink: the electric discharge from the electrodes, instead of passing along the shortest path, the case of a classic arc, was heading towards the opposite electrode. Which means that the electrical discharges crossed in the axial extension of the 4 electrodes, also forming a cross of Saint Andrew. At the point of intersection of two effluvia then a new fact, not observed until then, occurred and which the known formulas or laws of electrostatics do not account for. Only the so-called "power of the spikes" effect on a flame is known.

We insert here a remark made by Buffon and recorded by him in a little-known text that Mr. Cotton, the physicist who invented the famous balance, had shown to Sprink: "In the 18th century the aurora borealis were frequent in France. The dates of aurora sightings according to Buffon corresponded to frequent fires ravaging entire villages in northern France and Europe; the constructions were made of wood (the wood in the constructions being of more consequent use than now). Buffon, an observer of all natural phenomena, establishes a relationship between the two associated and simultaneous facts as well as the performance of blast furnaces with fires and the aurora borealis".

L. Sprink made a similar observation in 1938 during the aurora of January 15 visible in France accompanied by the destruction of boilers and chimneys.

The Sprinks experimentally carried out a certain number of chemical and thermal reactions in closed environments: autoclaves, furnaces, coke ovens, etc. by operating their device in a cross pattern nearby, noting very regularly and punctually the actual calories used in the classic reaction and the times spent to obtain industrially manufactured products according to the demand of the national and international markets in order to be able to compare their own production times and the real savings made in normally used fuel.

The first results were promising enough to be addressed to the industries concerned. We will briefly review a few of them.

d) Origin of industrialization and improvements of the Sprink device from 1923 to 1950

- i) Fundamental discovery of the autocorrelation of irregularities in the yield of a soap factory with respect to the activity cycle of the solar plasma and to the cycle of the earth's electric field.

In 1923 Sprink, in Strasbourg, owned a process for manufacturing soaps with high detergent power that a stearin factory had adopted. According to the boss of the factory himself born in this industry, it was known that the manufacturing "recipes" only "lasted" for a certain time with irregularities in performance and that then something else had to be found...

L. Sprink and his wife then carried out studies in autoclaves in which, with regard to production statistics, various cyclic laws could be established by a rapid harmonic analysis of the progress curves of reactions in autoclaves with regard to various daily, night and seasonal parameters. (equinoxes and solstices), annual, decennial etc., linked on the one hand to the positions of the moon and the sun and on the other hand to the terrestrial vertical electric gradient. A correlation could be established between the chemical thermal reactions in a vacuum with the aqueous and terrestrial tides as well as with an aerial "electric tide" (terrestrial electric vertical gradient) and the terrestrial horizontal electrotelluric activity which we currently know (since 1952) correlation formulas with terrestrial magnetism. It should be noted in parenthesis that the worldwide industrial developments of applied geophysics for the discovery of hydrocarbons have only been possible through the detailed analysis of several million measurement points of these various parameters, the effects of which we began in 1980 to master. laws.

Commissioning of the first device

The conclusions of the Sprinks were that to reduce the manufacturing from 11 p.m. to 3 a.m. (!) it was necessary to subtract the autoclaves and their reactions to the action of the aforementioned fields. A device for "grounding" the press frames was carried out which had the effect that in 1936 the factory was operating at 150% efficiency compared to 1932 taking into account the working hours reduced to 40 hours instead of 48 hours and without changing the "recipes".

However, although the application of the new process preserved the plant from the most troublesome fluctuations in its production, there were still peaks in the qualities and yields above the critical threshold.

- ii) Continuation of the industrial work of the Sprinks at their laboratory in Meaux (Seine and Mame) 1938-1940 and at the Cimenterie de Port de France from 1943 to 1944 with the aim of obtaining massive savings in fuel.

Around the 1930s, Mrs. Sprink was also studying the problem of the formation of cements at low temperature and had arrived at a very beautiful manufacturing process using the horizontal Mecker furnace. However, as in stearinage, the results and the yields presented variations linked to another unknown factor not linked to the terrestrial electric fields nor to the lunar and solar tides as regards the Newtonian action.

However, based on certain observations of the solar corona on the one hand and the appearance of the spots on the other hand, by correlating the anarchic deviations from the variations in the quality of the cements, it was established that the deviations were directly linked to the electro-magnetic activity of the corona (currently called the electro-jet) and to a terrestrial consequence translated into our upper atmosphere around 100 km altitude which are the aurora borealis.

In brief the law of interdependence of the phenomena of coronal radiation in relation to the two passages of the sun on the lunar nodes on the one hand and on the other hand the consultation of the variations in quality of the cements of Port de France (Isère) recorded over forty years of daily analyzes allowed cross-checking.

It appeared that the tensile strength of cements analyzed from 1898 to 1939 followed the cycle known by astronomers of 18 years 11 days under the name of Sarros. This cycle corresponds to 223 lunations or 19 times the interval of 346.6 days separating two passages of the sun through the lunar node.

It turns out that the periodicity of oceanic transgressions also partly follows the same law. As above, there appeared a correlation between these various phenomena and the physico-chemical balances of the reactions analyzed.

It was then that the Sprinks used their second device consisting of 4 cross-shaped aerial electrodes placed on a circle and powered by a stabilized DC high voltage source. This device was the subject of the patents mentioned at the beginning of our report. Chapter I, 1.2.

The coupling of the two devices was tried with profit at the glass works of Mers les Bains in 1949 where significant rises in temperature were observed for a reduction in the tonnage in combustion of pulverulent coal and fuel oil. Tests were also carried out in Brazil in 1951 in a lime potash plant. But the results remained inconsistent because the situation is complicated by the fact that the solar periods do not have a rigorously fixed duration and can present random periods of encounter with the moon according to variations ranging from 9 to 15 years.

- e) Attempt to develop a theory in the face of the complexity of the phenomena in order to fully master the chemical and thermal results, work from 1951 to 1955.

In view of the achievements already obtained on the lime kilns and in the manufacture of cement, the important economic element was reflected in a gain in fuel (coming from the same coal mine) which could reach a rate of 50 % without clinker. However, this economy did not follow a known law, which is acceptable considering the complex remote phenomena on which depend the thermal reactions in chemistry of high temperatures, the states of matter.

In short, the Sprinks carried out a series of tests which led to the following conclusions: at low frequencies of the magnetic field:

- 1) up to about 25,000 c/s the acceleration effects are related to electromagnetic resonance; at higher frequencies (from 100,000 c/s), an acoustic resonance is established.
- 2) the Sprink device is not an autonomous transmitter, but a local amplifying resonator whose excitation is found elsewhere.
 - 1) At low frequency it is an electromagnetic resonator, moreover thwarted by terrestrial radio emissions
 - 2) For the high frequencies the effective waves are of mass nature with hydrodynamic character.

After the tests on rows of vertical cement kilns, the only hypothesis of the effects observed simply due to electrostatic fields was insufficient, a spatially localized electric charge not being able to have an action over several tens of meters without any weakening, the electrostatic field decreasing with the square of the distance. So there was something else, because the device in its applications *was effective only oriented perpendicular to the earth's magnetic field.*

There remained a fundamental point to be elucidated: what was *the primary radiation source* ? the device being a "relay-resonator-amplifier".

During the tests on rows of lime kilns, another curious fact experimentally shows that the rise in temperature, the intense drafts and the unusual thermal reactions first appear at well-determined distances from the device arranged in zones. circular analogous to the known images of the rings of saturn with similarities of gaps reminiscent of the asteroid belts around the sun.

A phenomenology causing such effects was unknown until now and the Sprinks seem to be the first to have observed all these facts, to have analyzed them with the means at their disposal and above all to *make immediate use of industrial use.*

For the nature of this radiation, the Sprinks were reduced to hypotheses approaching the theses of Louis de Broglie on wave mechanics, in particular in the two different states: the vectorial and the pseudo-scalar as valid for "mesons" or heavy electrons as for the "photons". According to Maurice de Broglie, with whom the Sprinks were linked, interactions between particles via pseudo-scalar photons would be spin interactions.

It would therefore seem that the extreme ease of establishing homopolar links in the presence of our device in operation confirms this hypothesis.

In the conclusions and the mathematical developments carried out by Sprink it emerged according to him that the terrestrial electric and magnetic fields, as well as their derivatives and known slow variations, were subjected to other rapid variations at very high frequency.

Sprink admitted that the rhythm of the discharges of the device was regulated by the magnetic field which is perpendicular to them, that is to say the earth's field whose various rhythms are those of the phenomena emanating from the solar plasma.

Sprink considered that the field of his oriented device could be described as a variable magnetic field at very high frequency, without distorting reality, especially since the intensity of the currents used remains very low.

Sprink considered to be in the field of *mass resonances* which caused this radiation to be confused with simply acoustic waves, whereas at very high frequencies it is plasma vibrations which appear.

Moreover, in relation to the frequencies effective for the purpose sought, Sprink has made visible waves *stationary* by extending the electrodes with strands of red copper wire soldered to the ends. On these little strands

luminous points appear located at the nodes of the waves and correspond to the two absorption lines of the spectrum of rotation of oxygen of 2.5 mm and 5 mm. This gas could be the resonator par excellence of the primitive radiation. There is an analogy at the level of the solar prominences with the strands of thin wires and their luminous phenomena; in effect, *local reinforcements* of the brilliance appear on the photos of the paths that the expelled plasma travels in the direction of the crown according to the laws of hydrodynamics.

In the hypothesis of a *mechanism of the propagation of the mass field* Sprink excludes the propagation by electromagnetic waves because of the presence of standing waves, visible on the photos of the strands of wire mentioned above since the standing waves do not radiate. It also excludes material vibrations because the transverse waves physically observed near the devices do not propagate in a gaseous medium. Yet the radiation is linked to very significant ponderable effects probably amplified by *quantum resonance* in the reacting materials. Sprink thought he was in the presence of a *quantized pulse energy flow*. This way of seeing is in agreement with the development given by Einstein for the global weight-motive force.

In the analysis of the phenomena present there still remains that of the formation of a swirling magnetic field which can only be treated by the methods of wave physics. Sprink believed that this field could be described as a spinal field which could only be propagated by pseudo-scalar photons³

following Louis de Broglie's theory of wave mechanics.

9) Stopping of theoretical and practical work of Sprink and difficulties encountered with employees.

As can be glimpsed in the summary of the Sprinks' scientific and industrial adventure, the unusual, the complex, the permanent contact with unknown variables were the daily companions of the Sprinks.

From what we can know of their relations with the great international names in science, they have always been excellent, whether Maurice de Broglie, the Curies, the Cottons, Einstein or other contemporaries. who, while having admiration for the work of Sprink, were themselves too absorbed to devote themselves to a common collaboration.

In their contacts with factory bosses, the latter not being at the head of a study or research company, very often these heads of industry saw themselves obliged to consider only the economic aspect of things and asked engineers or technicians in their company to make their willingness to collaborate available to inventors.

At this level, the Sprinks have not always met with the understanding necessary to be perfectly followed. It should also be considered that their working hypotheses, especially before 1945 (Hiroshima), could seem incomprehensible to classically trained engineers working in the factories of that time. On the other hand, with regard to the foremen and the workers, very often enthusiasm reigned in the face of the results obtained.

After the death of Marie Thérèse Sprink in 1951, Léon Sprink devoted himself more to theoretical laboratory tests and to writings intended to leave a satisfactory concretization of the ten industrial patents taken out between 1930 and 1954.

The various industrial practical works of Sprink ended in 1965 for various reasons: the factories had disappeared, changed manufacture or had been reabsorbed by groups having opted for a policy or a range of different products. Moreover, Sprink had always been a relatively independent researcher and financed all his research and experiments himself in his laboratory in Seine et Mame, in Meaux, over the last years of his life.

L. Sprink built gravimeters derived from those of Jacobovitch for the study of the horizontal component of the terrestrial "g". Sprink perfected the apparatus by installing an optical effect multiplier and adding a photographic recording. For his studies, a collaboration was made with Mr and Mrs Labrouste of the Institute of Physics of the Globe and members of the International Gravimetric Bureau. The harmonic analysis revealed outside the periods like the luni-solar tides other periods and variations of horizontal "g" during the operation of the cross device.

In 1967 Sprink passed away as the last descendant of an old Baltic family of Protestant origin. His origin earned him a burial in the Cemetery of Sainte Geneviève des Bois, although he is not buried in the part reserved for the Orthodox.

4) Part III

a) Continuation of the work of Sprink - New developments.

After his death, a succession of training not being assured, the work of the Sprinks would have disappeared if a few particularly well-informed people had not put on the trail of these discoveries, the future of which could be considerable, a chemical engineer, doctor of physics -mathematics which took over the known theoretical part of the devices of Sprink and continued it by completing it masterfully with the contribution of new discoveries, in particular on the

³ The hypothesis of pseudo-scalar photons in the case of the work of L. and MT Sprink had been issued by Maurice de Broglie.

notions of emissions and absorption due to oriented forms as well as by the notions of "Location", "Global", "Offset", "Cumulative" [6],

This is Jacques Ravatin, experienced experimenter and theoretician who took over Sprink's experiments and had Professor Mesnard of the University of Lyon, director of the electronics laboratory of this University, note the amplifying power of the effects obtained in this way. than the Fractal character of these effects, of which Jean Perrin has also developed the physical consequences on the parameters of the physical fields linked to certain states of matter at the corpuscular level.

The practical application directly usable in industry with some of the enormous consequences that it represents is summarily exposed in the patent application of July 13, 1978 under the n°78 - 21083 deposited at the office Casalonga, 8 avenue Percier, 75008 Paris in the name of Mr. Jacques Ravatin.

b) Descriptive summary and experimental principles of Mr Jacques Ravatin's invention.

We know from experience that certain simple geometric shapes with a minimum of symmetry manufactured in very varied materials are, when they have appropriate proportions and a certain orientation in space, the seat of effects in their close environment which, not to be explained clearly, are ascertainable:

- either on living organisms or organically dead cells.
- or on metals on which a molecular rearrangement seems to occur.

The first observers used to describe the phenomena an ill-adapted expression: "waves of form".

It is more correct to say that it is more of a resonator absorbing or capturing locally a more fundamental notion than the energy emitting measurable effects following a certain orientation. But that's not it yet.

These industrially exploitable effects or more exactly become so thanks to the amplifier apparatus of Mr. Ravatin which considerably amplifies the phenomena according to a principle known as "localization" in which geometric shapes presenting a minimum of symmetry are associated with devices producing a field electricity, a magnetic or electromagnetic field modulated or not.

The various parameters allowing the amplification of the phenomena expected for industrial exploitation have been developed to the maximum. The start-up of the device to obtain the desired effects requires a time of about one hour for a noted action zone of about thirty meters.

The generator producing the electric potential must deliver a current of approximately 500 microamperes. It is gradually increased in voltage starting from zero to reach at least 124 kV.

c) Effects noted on Mr. Ravatin's operational model.

1 Action on the Earth's local magnetic declination of approximately 6° towards the west after half an hour of operation with variations in effects depending on the orientation of the frame.

2 Local action on gravitation at a potential of 100 kV it is noted that the local gravitational field increases to 0.9 times its value at the measurement point close to the device taking into account gravimeter drift corrections and lunar variation. tidal solar.

3 Local action on the air refractive index which increases the higher the positive potential applied to the serial electrodes.

4 Observation that in combustion reactions usually producing clinker, there is no formation of clinker during the operating time of the device and even 4 days after the voltage cut at the electrodes.

5 Decrease in the amount of fuel needed in conventional combustion reactions to achieve the same result. Saving 30% of coal is possible with a high voltage of 100 kV - 100 microamperes.

In the case of an internal combustion engine using gasoline, there is a reduction of up to 50% in fuel consumption for identical performance. However, the engine is stationary and not mounted on a vehicle taking changes of direction in space.

6 Increase from 1 to 2.3 of the solubility coefficient of a salt in water.

7 Increase in plant growth rate and size by a factor of 2 to 10.

8 Possibility of obtaining catalysis without catalyst.

d) Jacques Ravatin's approach to biology.

This statement has been deliberately restricted from certain possible developments *applicable to the industry*.

We have discarded the important observations made at the biological level and on human behavior from the point of view of fatigue and which have been noted by entire teams of workers.

Compared to the experimental model having felt in the first tests, the elaboration of the next prototype - object of the 1978 patent application made by J. Ravatin - is based on the data of his doctoral thesis in sciences presented in 1965 on the so-called "non-Cartesian" systems under the authority of Professor Mesnard.

e) Verification of the validity of the results obtained by Mr. Ravatin.

Professor Mesnard, director of the electronics laboratory at the University of Lyon, supervised the experiments resulting from the theories of these non-Cartesian systems and monitored the experiments carried out.

It should be noted in particular that this new experimental physics theoretically and practically reveals a notion to ponder: the usual physical measurements, however fine they may be, only indirectly account for certain observable facts and in a fragmentary way.

EUREK'ALL

The approach to the phenomena observed and highlighted under the control of Professor Mesnard by J. Ravatin involves the notion of "Fractant".

It appears that taking into account the foregoing, the findings and all the facts proposed for our analysis by the developments put forward and obtained before Professor Mesnard by J. Ravatin cannot be analyzed solely from conventional measurement methods. accounting if we can say that for the "spillover" of integrated facts; from the origin of our galactic system.

f) New ways, appropriate semantics

Understanding and mastering the desired effects requires a terminological redefinition developed by J. Ravatin in which the expressions "Global, Local, Cumular, Shifted, Cumulo-Shifted and the concept of Fractant" appear.

The aim pursued in the construction of the future prototype is to demonstrate by amplifying them the "bursting" effects of the classical space-time structure. The practical results will have industrial consequences on the level of chemistry and metallurgy - to quote only these two industries - comparable to those of the repercussions of the conquest of space with an initially more immediate ease and a saving of obvious energy. The progress made compared to the work of Sprink from 1925 to 1965 was possible thanks to the integration of notions unknown at that time both in relation to a better knowledge of extraterrestrial space and to the improvements made by J. Ravatin .

g) Consider the future of a post-industrial society

We can predict that following this work developed over decades, we find ourselves at the dawn of an era in which the conceptions mentioned above will take on more and more importance, if only in due to the global energy situation. From Léon Sprink's little sun to Jacques Ravatin's fractants, don't we find ourselves faced with a reconstruction of a universe as Einstein expressed it to the Sprinks... but could we add the industrial universe of the world of tomorrow? in the face of planetary responsibilities never before encountered. [4] and [5],

Let us point out the stability of the phenomena obtained by J. Ravatin and their reproducibility.

There are also thresholds which are given by the voltage, the dimensions of the device, the forms involved. If the conditions imposed are neglected for reasons of economy, it is not possible to obtain certain effects. [7],

The capabilities of the Sprink apparatus can be considerably improved by the addition of forms suitably chosen and arranged around the apparatus; we thus obtain the Avaecum discovered by J. Ravatin and the fields Z and ZD discovered by J. Ravatin and AM Branca.

I. Introduction

The chapter does not include an exercise. On the other hand, the examples given will make it possible to grasp the concepts. It should be read carefully. We are gradually entering the new form of thought which makes it possible to set up a model: the Theory of the Fields of Consistency.

II. Structure transportation ;

Let us consider a form F, for example a living being; we talk about his condition.

Thus F -X2!ëÿ <state of F sets up what we call the way when we want to go from F to state (F). This creates a path.

Let's consider a shape G on which we will apply this path. We will get thus state(G).

Let G -Yaie~> state G

Through the track, a "structure transport" is thus obtained. You can enrich a domain by bringing him by a way a concept which a priori did not exist in this field.

We saw in the 11th level lesson that certain states are characterized from words written, for example, in square Hebrew. This corresponds to states that are no longer representable in today's thought but the square Hebrew kept the information which allows you to go back to the state.

Among the states, some will relate to an impossibility for the human being to approach a domain; it may be that the result of a lack of knowledge, of wisdom of the one who works, or else the index that the mode of thought adopted is not adequate or that certain concepts are not accessible to human thought. That last remark disappears if one has faith in the human being and especially the thought, since nothing does not exist outside of it.

III. COHERENCE y FIELDS OF COHERENCE

THE LOCAL, THE GLOBAL, UIDATHEME

Necessity is a concept often used in the everyday world. He intervenes in this course as an effect of a tension between concepts, situations.

As we will see later, we will only very rarely give definitions. These freeze a thought. They excel in rational thinking which is a static thought: which means that this thought evolves in time but does not is not expressed in the moment, that is to say that a definition does not have course in thought which we have called "vertical". This "thought" is such that when one constructs a schema, this one and all its consequences are in place with it; it's the thought called "fast" by the American Indians.

The instant is not a point on the mathematical representation of time which is that of the line R of the real numbers; it is not this point of this straight line which can be considered as a time interval Δt tending towards 0. The instant does not fall on $A! R$ emerges from the moment. In a sense, the instant is more eternal than time which, time of clocks, will never contain eternity.

The concept of eternity is interesting because it indicates much more than a scale of unlimited time; it indicates that but also a state, a state about which any measurement is permitted but does not satisfy.

Consistency will not be defined. It is admitted because deeply felt. She is not not measurable, it is not existence in a place; she is only face on cerebral constructions, on objects, systems of objects. She is a combination subtle between face and memory⁴.

Coherence is existence; we can add the field character to it even though it there is no realm in which to place it. But as in poetry, in literature, expressions are taken from contexts and carried into other contexts; this process thereafter will be named: transport of structure. Thus the concept of field, by transport of structure, of extension in the usual sense will approach that of depth, but to this depth will not be added a new dimension.

The coherence fields, which will be presented in this course, are first established by necessity, then by the aesthetics of the human spirit which they reveal and oblige to reveal by multiple, changing, wandering structures that they espouse, energize.

⁴ We will see more and more that combinations of terms and expressions of the usual C. of C. make it possible to escape from the usual C. of C..

To achieve this, it was necessary to implement new concepts by unusual constructions and arrangements in ordinary thought between concepts, constructions being themselves often concepts. All this makes it possible to escape the Coherence field (C. of C.) usual (or rational) to build another field of coherence (T Other Coherence Field).

There will only be two C. de C..

This expression Field of Coherence was imagined by Bernard Vivès.

The C. de C. were presented at the Institute of Physics in Bern as well as at the Academy of Sciences of Paris (1960). B. Vivès worked from 1964 to 1968 at NASA in a team of eight people. The theory of C. de C. was clarified by these researchers; they came to see the planets as balls of yarn, geometrically wrapped ribbons. Thus the spherical appearance was sometimes retained but we had more to do with formless magmas. B. Vivès uses what he calls the "Extensible Calculus" which is expressed in the so-called "extensible" functions and those here, thanks to their folds, entering into a model which, for example, tries to explain the succession in time of two genera of vertebrates without there being any link between them.

Extensible calculation prefers to forget any notion relating to geometries to stick to the idea of breaking the plan⁵.

We will not pursue this path any further, which must have been fruitful but which is remained totally ignored for military reasons, educational stability habitual of crowds, and for the safeguard of physics in which one should not

ÿ B. Vivès, when he established the Coherence Fields theory, considered two such fields, or even many more. In the theory which will not be described in this booklet and which V. Rosnilk [4] has already outlined, there will always be only two. The expression Field of Coherence will therefore have a different meaning from that of Vives. Like Vives, the theory will have a mathematical structure and a physical meaning. But both the mathematical formulation and the physical model are different from what has been deposited at the Institute of Physics in Bern and the Academy of Sciences in Paris. Vivès had developed what he called the "subdifferentiated lattice theory"; the lattice structure is well known in mathematics but he elaborated lattices with special properties which he cataloged as subdifferentiated.

As for the theory presented here, it is based on a notion of wandering with wandering function (which Vivès also used) then involves the flight of reference points and then, non-Euclidean geometries in order to describe paths of points wanderers. [4] and [7]

touch on the principle of conservation of energy and the second principle of thermodynamics. We must not forget that with rational thought, places and attaches an economy that muzzles human beings in order to employ them better and make them act in very specific ways and goals. The handling of money is stable only by accumulating financial transactions. It seems that they have dynamism. Indeed there is one but it is only an aping of what we will present of the dynamism linked to the Other C. of C.. The stability of a power of money only holds by sprawling and repetitive effects. Faced with this we let's implement the concept of "Core Core". It's a form, it's a system that self-amplifies. He does not draw from his exterior; he draws from himself through processes that say that the hard core is pregnant for some of its properties. These properties will be considered later. They do not place themselves in a rational description of the world.

We are putting in place, little by little, an approach that will establish constructions between concepts; we would like to point out that these compositions between concepts can seem strange in the sense that they give rise to other concepts which have no nothing to do with components. This is very important and should not discourage the reader. Moreover, if we observe, in everyday conversation, comparisons which are insertions taken in themselves, having nothing to do with the ideas considered but simply by their structure, rhythm, are very often used. We find the metaphor in poetry; we will use its construction but it is also very present in the usual language.

In the rational world, we direct ourselves, we behave thanks to what we call markers, units and the transport of these units.

Thus are set up units of length, surface, volume, time, units of force, electric current intensity, electric voltage, field flux magnetic, hydraulic current flow, etc. the units are legion. These and their

transport which is carried out by the operations: addition⁶, multiplication make it possible to describe and evolve in what we call the "Local".

The room seems to be the same for everyone, which seems to reinforce it in its stability. This stability of the premises is at the same time a trap because the elaboration of the Consistency involved in its implementation is continuous; the language attached to rational world is extraordinarily precise, which facilitates division and gives thus full freedom of analysis.

We will postulate existence without landmarks. This will be the Global. Existence without landmarks will make it possible to attach to the Global what is not identifiable. Forms, such as us will consider them, will be for some related to the global but will not be in the global which would imply a relationship of belonging, container and content, of set and element. The global is not composed of elements, it is existence without landmarks. He is an evocation. It is both evocation and existence. These are related in some way that is not a tension.

The global is by the fact that everything that is not identifiable is linked to it.

Consider the notion of Love; we know that love is not measurable, not identifiable, one cannot place any unit on such a concept. love exists but is not identifiable; it is linked to the global. The same is true for the concepts of suffering, fear etc.. Some of these sensations support a relation of partial order (larger fear that..., greater suffering than...), partial because we cannot compare on all scale. Moreover, the imposed scale is not stable. Excruciating suffering do not compare for the same individual and it is impossible to want to compare suffering between individuals. Pain can, in some cases, be comparable, we will say support a scale of value, but this "intensity" of pain, in the extreme cases, no longer exists; the ladder becomes unstable.

So these attempts to map scales associated with localized concepts dilute the scales. The pain, the suffering is not entirely localized, shall we say.

⁶ Operations are an expression of the transportation of units.

It may be argued that some concepts are subjective and others are objective; this is in full in the language of the rationalists. As for us, we will never use these two terms for the following reason: the words carry within them the intentions that contributed to their elaboration, their implementation in the language and the evolution of the language. This is which is too easily forgotten by the rationalist who, in this way of thinking, has frozen the word, has above all frozen his own appreciation of the word.

Thus using the words "objective" and "subjective" will immediately lead to the return to the rational C. of C.. And you have to convince yourself that removing from your language certain words is not an operation of impoverishment but that, on the contrary, this prudence is one of the necessities to get out of the usual thought and to build a dynamic thinking. ^H

Words have their power, their density and impose a direction in the implementation and the expression of an idea. We must not forget the tacit knowledge, and the words in are impregnated, at least some.

The Global, for so-called Bourbakist mathematics, has no meaning because in what we very often consider, the set and the element are indistinguishable. They will be able to place themselves in "dynamic duality" ⁷ 8 in the Yin-Yang sense of the expression, i.e. to say that there will be neither set nor element and both set and element⁹. But keep this point of view is binding; it is necessary to consider another involving internal dynamics. Then the word becomes a sign which will evolve and then the word can own what we call a "Nebular" [4] (volume 1).

Note that this nebular word was imagined from the word nebulosity and this in the purpose of evoking. Evoking is the beginning of a path in thought, of a construction cerebral; one can remain with the evocation for that to which one is addressed; the evocation goes develop in itself in a path or as a construction.

⁷ Certain words, in this case these two, used in descriptive developments of states, situations, cerebral constructions, will bring these states, situations, constructions back to usual thought. This will mean that we will approach non-rational phenomena by the usual thought which is not adapted to them.

⁸ What we will see later.

⁹ This is a way of expressing in rational thought a concept that is not there.

Naturally in rational thought this pictorial representation can be considered as a popularized approach. This is not a problem since this thought cannot assimilate this concept.

We will see later that there is not a single room, but several “rooms”; one local may be imperfect, with breakages; there are such breaks in the room placed in place and explored¹⁰ by rational thought.

We set up the local and the global; the local emerges from the global or is immersed in the global¹¹ by what we have called with B. Vivès the decalaires and by the concept of cumulaire.

Then recently was clarified the concept of "Idathème" created around the years 1984-1985. The Idathema is a third type of existence, absolutely impossible to represent by the human mind.

We saw :

- Existence with landmarks: the Local, one of the different “locals”.
- Existence without landmarks: the Global

We now have another existence:

- The Idatheme

As for the Global, we will say of a form that it is linked to the Idatheme. Shapes, places, acts, intentions are linked to the global or to the idatheme or to both simultaneously.

It is easy to imagine existence without landmarks. On the other hand, the existence of the idatheme is more difficult to assimilate. We will give some examples of concepts, places, forms linked to the idathema.

- Certain constellations.
- The characters of Easter Island writing.
- Curves like the cycloid, the tractrix.
- All the statues of Easter Island; on the other hand a statue alone is not linked to the idathema.

10 (Note from Anne-Marie Branca): "set up" and "explored" are to be taken simultaneously. But when we reason in this way, we are no longer in the usual way of thinking. Such “comparison” between an expression and a word makes it possible to escape the usual C. de C..

11 The term “immersion” was chosen by Marc Beigbeder (private communication to J. Ravatin).

- If a human being stands behind such a statue, it becomes linked to the idathema and him too.
- If to a shape like an egg we run through the labyrinth of the Cathedral of Chartres, it becomes linked to fidatheme whereas the egg form is not, and it rest after the course. If we go looking for an egg on a rock - party made a times a year, by the Pascuans - emerging from the sea and brought back, the egg is linked to the idathema.
- The fog is linked to the idatheme; clouds can be.
- The mandrake is linked to the idathema; whether it is soaked in cold or hot water, it disappears; ditto if we grind it.
- The Philosopher's Stone is linked to the idathema.
- Arcadia: name of a valley in Greece where men met the gods, is linked to the idatheme.

Often the forms which are linked to the idathema emit from the avaecum, some eifs like VC, FV and also yews.

But the black madonnas while linked to the idathema, emit nothing of what one comes to report; they begin to emit if we pray in front of them.

- Georges Claude and Coutelen's apparatus is linked to the idathème. ¹¹
- The device of Léon and Marie-Thérèse Sprink, those of Louis Boutard are not linked to the idathema. ¹¹
- The devices of JW Keely, of Th .Moray are linked to the idathème. ¹¹
- Loch Ness Monsters.
- The Yeti.
- Large sea serpents.
- The animals drawn on the Nazca tracks are linked to the idathem.
- The magic squares, the Sator square, are linked to the idathem.

See [4] and [7],

- **Montségur castle was linked to Lidathème but is no longer.**
- **The Ark of the Covenant was linked to Lidathème.**
- **The DNA double helix, a beaded dodecahedron are linked to Lidathème. If we add a central ball with the pearl dodecahedron, one detects the 22 arkkhams. Moreover the one this, when performed, acts on all those without a central ball and causes them to emit all arkhams. It is the presence of such a beaded dodecahedron with a central ball that entails properties on others. This existence does not need neighbors.**
- **Water circulating in a half-pseudo-sphere is linked to Lidathème; if we replaces a half-pseudo-sphere with a hyperboloid, this does not happen [9], Victor Schauburger had chosen a hyperboloid; he had left work for that de Képler.**
- **Egg white and other colloids are linked to Lidathème.**
- **Louis Boutard's gummy water, Wilhelm Reich's viscous water are linked to Lidathème.**
- **The dolmens, alignments of Carnac, cromlechs are linked to Lidathème. One menhir alone is not linked to Lidathème.**
- **A very large animal or human figure drawn on the ground is linked to Lidathème. Such designs are particularly found in the English countryside.**
- **Boves and Nouraghes are linked to Lidathème; when we get in we take the properties and when we leave them we keep them for around 4h to 4h30. This allowed, in doing rituals in these places, to direct the ritual, to amplify it.** ^{*1}

13 Boves: Nicolas Germain [8] did a search to try to identify the word bove; 11 note that this word is not found in the usual dictionaries, but that the "Etymological Dauzat" of 1938 gives the following details: Bove: regional word already known in the 12th century by Guillaume de Tyr - Historian of the Crusaders - means cave, rear -cellar. Bove would come from the combination of two words:

- (1) Gove - 11 would come from the Germanic Gaupa meaning hollow of the hand - it is the Cauchois word for the cave.
- (2) Baume -11 would come from the Gallic Balma in the VIIème century - grotto of the hermit -.

Many of these Boves are listed in the work of Maurice Broëns [10] - Honorary President of the Société Française d'Etude des Souterrains. He describes in his book [10] the unusual works existing in Europe: tumuli, underground structures of which the boves are part.

The most beautiful bove is in France in Neuville-sur-Touque, in the Pays d'Auge, in Normandy. She is on the so-called property of La Jaunière; this property was bought in 1935 by doctor Robert Chaudet

The idatheme is an existence which is not linked to the global, it is characterized by the fact that it is "to be being". This, to be understood, must be thought of as a whole, without being decomposed.

Now consider Idatheme, Global, Local as well as Soul, Spirit, Body. We have two sets of 3 items each. In general there is no correspondence of par their characters between them (one can of course impose correspondences by mathematical applications, but these are done a posteriori; in some cases they transport properties from one set to another). Here the correspondence exists of by what we feel on the trio: soul, spirit, body; what religions present but do not explain, which has given rise to multiple uses of these three terms depending on the contexts in which they are immersed.

While here, we immediately feel the correspondence:

Ame —> Idathème

Spirit —> Global

Corps —> Local

now deceased - and his wife. He immediately visited the bove but at that time it was more complete than now, because collapses occurred.

She had a stone table - seen by the commander Mouton - which was destroyed by vandals. This is the reason why the owners prohibit access; nevertheless, it is not only vandals who are dangerous in such places; archaeologists who absolutely want to restore for the good conservation of the place, not understanding what these artificial caves could have been used for, risk distorting the signs or shapes engraved in hollow or appearing in relief. For many of these researchers from the CNRS and elsewhere, the boves are troglodyte dwellings - they scratch, dig to find traces of hearths, tombs and they scratch again; and so they claim that the boves are granaries for food, refuges during the French revolution, arms caches during wars.

The Neuville-sur-Touque bove is surmounted by a wood which may have been cleared - 4000 to 6000 years ago - when the bove was in use. Circles of earth, concentric appear in the wood. They could amplify certain effects triggered in the bove during powerful rituals.

These rituals were to last for a long time. In particular, they awakened the "Chthonic Forces" (these will not be described in this booklet). Ceremonies, in the open air, above the bove, could take place during the full moon [4].

Graffiti on the threshold of the bove served to block the establishment of certain harmful states, or to purify the officiants as soon as they entered the place [4]. In the boves the rituals were certainly very long in order to trigger the phenomenon. It probably took several people, who succeeded each other day and night, so that the bove was never empty and who all the while, worked to obtain the information requested; these depended on local folklore and the era.

Nouraghes: they are fully described in a book by F. Niel [10]; they are alone or in groups. They are found in Sardinia.

EUREK'ALL

When we speak of the body, it is the localized being that we are considering. So he is in the local. The mind is completely delocalized; it is linked to the global. The soul, on the other hand, is linked to the idathema; it is "being being". To verify this correspondence by tests it is necessary follow the steps above, otherwise nothing is found. This approach is the equivalent of a detection device [5].

Erratum :

For the sentence of Johannes Wolfgang Goethe quoted in Fascicle 3 of the second level, it should read: "We wishes are the presentiments of the faculties which lie in us, harbingers of what we will be able to accomplish"

Chapter VI

*I. Digression on the expression " **Rupture of compensated forces** "*

We find this expression in a certain number of books where it is a question of forms.

The "rupture of compensated forces" would be an imbalance between the "cosmic" and the "telluric".

First, there are two meanings to the expression "telluric currents".

- **The rational sense:** these are electric currents in the ground due to differences in humidity soil or different kinds of rocks that create ions. These currents can manifest over great distances.
- **The esoteric meaning:** it is sometimes eifs sometimes eims - E for emergence, I for influence and M for mass: discovery by P. de Montgrand; eims are different from eifs; they don't will not be presented in this booklet -.

There is also what is called the "Wyvern" obtained from eims sent for example on a twisted wooden cylinder. The wyvern is composed of makhras which are 56 in number and quite fact other than eifs or eims.

Let us note that in the phenomenon primes with the rupture of forces compensated, one does not know if it is about telluric currents in the rational sense or in the esoteric sense or even the mixture of the two.

We are now going to set up a concept which will make it possible to present this phenomenon not not linked to "forces" but to a property of space.

Broken symmetry: the concept of broken symmetry was introduced first in physics: theory of elementary particles and also in crystallography but it gradually extended to other fields of physics. For this we consider a symmetry group in which a phenomenon,

© EÜRECALL

a situation are invariant. A situation can in the course of evolution satisfy only a sub symmetry group of the original group. In this case we say that for this situation there was a break of symmetry.

We have a broken symmetry when an asymmetry appears, putting Curie's principle in default in a physical phenomenon. In some cases, it comes from the asymmetry of physical laws (eg violation of P in the decay of the K meson into pions); in other cases (crystallization, occurrence of turbulence).

Consider the path: Physical system $\xrightarrow{\gamma_1} \gamma_2$ — breaking the symmetry of this physical system and consider the scheme already used: Un certain concept $\xrightarrow{\gamma_1} \gamma_2$ — Space of the usual C. of C. That is to say by the inverse operation - that we will write (channel)'1 -

Un certain concept $\xleftarrow{\gamma_2} \gamma_1$ — Space of the usual C. of C.

This concept will be named for ease of expression Space before the break either EsAv (for Front Space).

Thus Es Av $\xleftarrow{\gamma_2} \gamma_1$ — Space

There are forms that allow to pass from Space to Esav and also these forms allow to consider a new type of shapes that we will call shapes before breaking: Esav-Shape.

In the couple man-woman, the difference between the man (M) and the woman (F) comes from the way above.

We can go up by (path)'1 acting on {H, F} and we obtain the entity before the break.

(way)'1 the water entity) provides access to a very interesting entity. One can think of the "waters of top" of the Bible.

The "rupture of the compensated forces" corresponds to a region where we can go back to the Esav.

This is very interesting but it is necessary to know how to use this region.

© EÜREECALL

So in the terminology of the waveformists¹ there were these regions in imbalance between effects cosmic and telluric effects; this, again for them, leads to the detection of a V in the Sun.

Some designs from our ancestors: _____

We are not going to delve into all that archeology and architecture have left as witnesses of our predecessors; but only attach ourselves to these few characteristic milestones which are the menhirs, dolmens, pyramids.

Perhaps they will facilitate our journey, even if it is not obvious at first sight and even then...

a) the menhir

This vertical stone, erected in prehistoric times, was not to embellish the landscape - one can think so - but in view of a function to be fulfilled that the rational world does not know more and is unable to apprehend.

If we examine the rooting of a menhir in place, with a pendulum or a rod, we find ourselves we can see that this monument is very often linked to telluric emissions. But which ones?

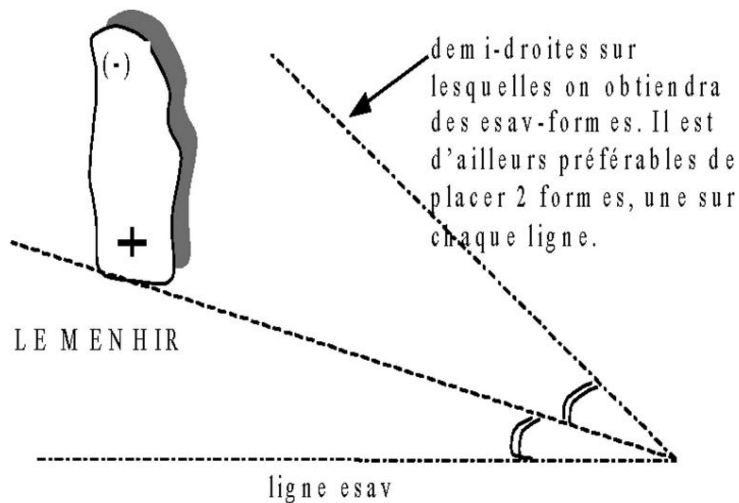

We then detect eifs or eims, with which states are sometimes associated.

If these are harmful and the states also, they will have to be removed to maintain health as well. both physical and moral.

The menhir is interesting in this case to rebalance the place. What is very important is that the "force breaks" are the diagram of a possibility of using the Esav. A person who is on one of the "force break" lines happens to be a form before the break, an esav form.

¹ For those who deal with "waves of forms".

Many such systems now no longer work. It should not be inferred that for all the menhirs planted vertically there is the possibility of passing to esav-forms. Moreover, the menhir alignments do not have this property

Exercice 1 : Il faut deux opérateurs.

- One rotates its pendulum vertically along a line of Esav of form - called line of esav -.
- The other walks around in the immediate neighborhood letting take between the thumb and the index finger a wooden broomstick held from above.

To verify :

- 1) that if the + of the handle is at the top, the pendulum of the first operator will not stop.
- 2) that if the - of the handle is up, there is a chance that a position on the ground of the vertical stick stops the pendulum of the 1st operator.

Then locate the place.

To verify :

- 3) that the handle held vertically is on the vertical of the bisector of the angle of 2 concurrent esav lines.

It is recommended to have explored the surroundings so as to be sure that you have detected previously the lines of esav.

Consequence: The broomstick is replaced by a very small menhir weighing a few kilograms.

Check that this stone has only 2 polarities and that they are + for one and - for the other.

Place the stone in such a way that the + polarity is at the bottom and the - polarity at the top.

The line joining the polarities being vertical; it is necessary to arrange so that the shape of the stone achieves this by giving the impression that the stone itself is vertical.

This vertical must pass through the interior bisector of the angle formed by the 2 lines of esav concurrent.

The stone should have a wedged base, but not buried, however slightly.

Remarks :

- 1) if it is considered that the menhirs are linked by their position to lines of esav, it is necessary to clear them their base if it is no longer and perhaps straighten them.

But all the menhirs do not correspond to 2 such lines and their raison d'être was perhaps to use the esav lines or something else altogether.

- 2) When the menhir is placed like this, the lines of esav are destroyed unless a human being is placed standing, on the interior bisector of the 2 lines and quite far from the menhir.

- 3) At the esav lines was detected V'e. So we are in an unhealthy place.

Indeed the V'e is quite harmful but perhaps it was used for beneficial purposes by the Elders?

- 4) Is the menhir a stone of fertility intended to make crops and animals prosper?

- 5) Or has the stone acquired special properties like some of them which seem polished by force, perhaps, by the bellies of sterile women?

- 6) Or was there a network of menhirs with functions determined by their positions respective geographies?

New results about the menhirs: the menhirs can be considered as waiting
of use. That is to say that under certain conditions: rituals, disposition of forms - even
human - in the vicinity of the menhir, one can generate special fields - which are not
of an electromagnetic nature -, which we have discovered and which are called Z and ZD fields. They
seem localized.

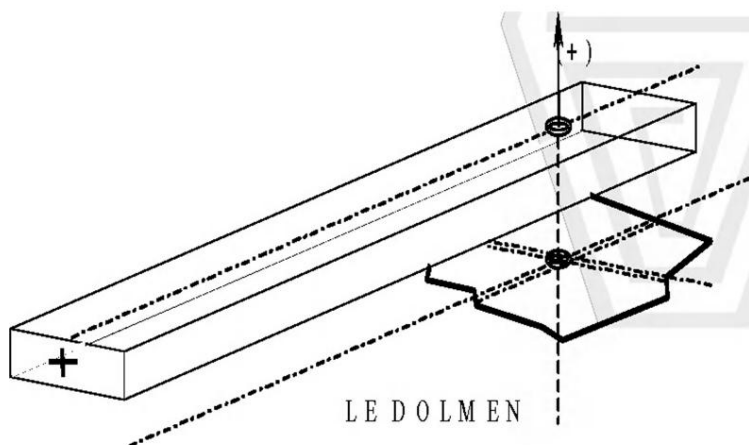

The applications of these fields are multiple: by acting on these forms one generates eifs,
but also the "universal currents" of Louis Rota - an Italian researcher who worked in France and
builds devices for medical applications -

We must always bear in mind that the Ancients did not think like us and did not see the
same world as the one we live in. They must have been more aware that they
were building the world. They were much more flexible in the face of unforeseen situations. They
lived close to the cerebral mechanism which is wandering-unexpected seen-wandering-unexpected-wandering...

b) the dolmen:

Here the stone is a horizontal table carried under tension by vertical pillars so as to
provide a covered cavity underneath.

The observation of the dolmens and covered alleys brings to realize the following remark: they are
east-west oriented. In addition, a crossing of esav lines is detected near the eastern end of the
dolmenic table. One of the 2 East-West lines follows the long axis of the table, the other, North-South, is
perpendicular.

© EÜREECALL

Exercise: Drill the ends of a naturally polarized wooden board on supports of same height so that the board is horizontal.

Make a picture of the crossing of the lines of esav by drawing two lines perpendicular on a piece of cardboard - like bristol -, by piercing the intersection with a cookie cutter and turning the cardboard over so that the lines are on the bottom.

- 1) Move this upturned cardboard under the board. At any position, the + of the board emits the life node. Check it.
- 2) Also check that there is a position of the cardboard under the board that makes this vertical emission of the life node.
- 3) by specifying the location by repeating the operations and by fixing the eif thanks to a small copper ring placed on the board, we see that this point is 8/10 of the length of the board, going from the + of the latter to the -.
- 4) Note that the eif V e of the cardboard is transformed into V+e

Consequence: can we rebalance ourselves by lying on the table of a dolmen or by staying lying or squatting inside? - assuming that there are still dolmens today functional -. In part, yes! But if we have a weak ext, he will remain so.

Other Considerations:

- 1) As for the raison d'être of the monument, it remains in the conjectural domain. This does not prevent not to admire in passing this technique and these technicians who brought a precise point of a stone weighing tons or even tens of tons vertically from another point

just as precise. Finally it is that we find from the preceding considerations on the forms.

When we are in the dolmen, we detect the esav. That is to say that we go back to the richness of the esav forms.

Naturally the people of those times knew how to use their concepts because of their type of thinking.

We can then think of the extension of a physical property towards a religious or magical objective; it should be remembered that for the Ancients - and they are part of it - there was no division as in

© EUREKALL

rational thought, and religion, science, philosophy, morality, art were one and the same entity.

2) 8/10s got their check by crafting a very simple mood rebalancer

with remarkable efficiency. Just drill a hole right through 8/10 of the length of the axis of a board and to orient it - hole towards the east - at 85° magnetic. We eliminate thus a V'e ; the larger the board, the denser its wood, the more V'e is eliminated from it. this can also help put a polarized body that has rotated 180° back in its place. House will not systematically remove states like |K Sh Ph with inverted Sh>.

c) The pyramid structure

It has given rise to many works and commentaries, especially in its realization which is that of Kheops.

It is still the class of pyramids with a square base and an axis of symmetry coincident with the height because one can imagine multitudes of pyramidal shapes.

Another very interesting shape to study is the cone and even the double cone which is the rhombus.

The Ancients, Egyptians, Hebrews, placed the rhombus in some of their ritual apparatus. We will see this later in this course - it is necessary to refer to the work of Louis Boutard -.

Let's see some development on the pyramid of Cheops.

• The Pyramid of Cheops

It is useless to dwell on a monument which has given rise to so many works, articles, talks. Let's get back to basics.

The dimensions, according to recent data, are as follows:

230.36m. < base length < 230.40 m.

height: 146.60 m.

The measurements are precise enough to measure an apothem of 186.44 m.

Taking the half base as unity, we have:

<u>Apothem</u>	<u>186,44</u>	
half base	115,19	1,6185 ~ 1,618- Cp
<u>Height</u>	<u>146,60</u>	
half base	115,19	1,2726 ~ Vcp ~ 1,2716

One can reasonably admit that the pyramid of Cheops was built according to the Number d'Or Cp, which, reduced to a half base unit, gives:

$$\text{Base} = 2 \text{ Apothem} = (p \text{ Height} = \sqrt{2} \sim \text{Cj})$$

Here we are therefore facing the Golden Number Cp and not the Radiant Number VJ/. Yet we feel V// greater than Cp; first because the forms constructed with V// do not respond to K Sh Ph with inverted Sh> while it is often the case with Cp - see the 1st level lesson in which it was pointed out that Cp intervenes on fixed forms, which can still be alive (Fibonacci sequence whose first terms are related to the growth of plants), and that intervenes rather for forms in movement Moreover in a certain number of forms where one found (p, G. Cordonnier, the discoverer of VJ/, has verified that VJ/ has also been found. Note that is not the case with the pyramid of Cheops.

The Cheops pyramid is actually a truncated pyramid: the dimensions given above correspond to the truncated pyramid and not to the pyramid which leads to some errors in the results of the calculations.

Orientation is key. This pyramid has its faces perpendicular to the cardinal planes.

• Digression on Gizeh

Giza is the current name of the huge necropolis of ancient Letopolis (now Cairo). She extends over a plateau, leveled by man 4500 years ago, with an escarpment on the southeast side descending 40 meters below. At the foot of this plateau once ran a channel of the Nile separating the desert area of the fertile land.

© EUREKALL

The main monuments are:

- The Sphinx
- The Great Pyramids - one of the seven wonders of the world, the other six were:
 - The Lighthouse of Alexandria in Egypt,
 - The Mausoleum of Halicarnassus,
 - The Temple of Artemis in Ephesus;
 - The Colossus of Rhode;
 - The Hanging Gardens of Babylon;
 - The statue of Jupiter of Phaedias in the Temple of Olympus.

The pyramids are placed diagonally from north-east to south-west, so that none hides never the sun to others. In the field of shapes, shadows have amazing properties.

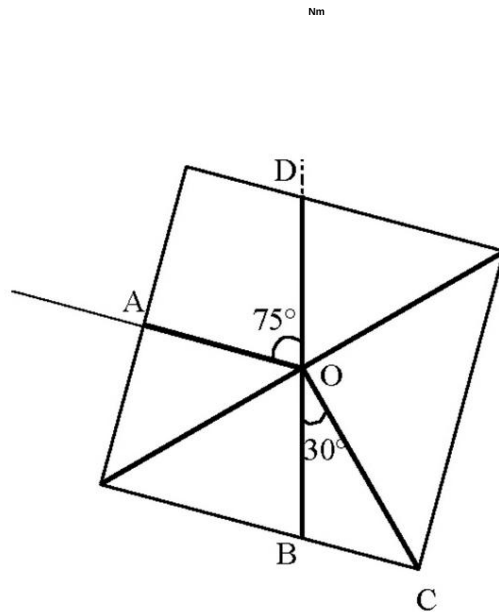

They can sometimes be colored as Goethe pointed out.

The first two pyramids are almost the same height at the top, because that of Chephren is lower but its base is higher. The three have their burial chamber in the rock, almost in the middle of the body of the construction. The pyramids of Cheops and Mykerinos have other superimposed rooms. All have their complete monumental ensemble: funerary temple upstream, communication gallery and downstream temple; Chephren is the best preserved.

Chephren and Mykerinos have three satellite pyramids, Chephren probably only had one. The sacred boats buried around the temples above Cheops and Chephren were perhaps be many.

But despite the rooms, the corridors, they are almost full. And it is this "almost full" that allowed us to discover what we presented in the course of the 1st level and that we called Ext.

Exercise :

Verify that a genus pyramid

Cheops, thus oriented with respect to the

Nm emits the escape of the C. of T..

It also emits many other thing.

Note that OABCD is the the 1st form-imprint.

• The Cheops pyramid (continued)

The true pyramid of Cheops gives V'e at the top and 1'UVÍe at the base. She leads in the connecting to a disk or square transmitter a 180° rotation of the polarized body.

These inversions may surprise and what we know of Egyptian beliefs is not enough to give the explanation.

It is difficult to invoke the following argument: the Egyptians believed that the survival of the dead required the preservation of his body, hence the mummification obtained, not only with

chemical preparations, but also by a set of processes which reverse the process of decomposition, in particular by the rotation of the polarized body, by the V'e which is detected at 1/3 of the height of the pyramid from the bottom.

© EUREECALL

It is classic to mummify a third of the height of a cardboard or plywood pyramid;
it must be oriented like that of Cheops but you have to pay attention to the neighborhood; that
orientation is sometimes to be modified. In addition, people complain of not getting the desired effect.
on their piece of meat. This is due to the neighborhood; they place the pyramid on a table with a
drawer, above the drawer, or on a bookcase with compartments. It changes everything! We no longer have the V'e
which removes the water from the meat.

In the case of good orientation and good neighborhood, the case of the almost empty pyramid is not
like that of Cheops which is almost full.

In a cardboard or plywood pyramid, there is no UVIE at the base and V'e at the top.

On the other hand, we always find the V'e at 1/3 of the height starting from the base.

Let's use some concepts that will be presented at the end of this booklet:

The pyramid of Cheops, at a third of its height, has a decalage. This is not the case of a
almost empty pyramid. On the other hand, the latter has a channel at a third of its height.

Shift and channel are indices of possibilities of delocalization or localization.

Here we must pay attention to the language used. At a third of the height starting from the base, we detect
shift or channel but 1/3 of the pitch is precise whereas shift and channel link to the global.

This comes from the fact that we use the language of the usual C. de C. but that we are attached to concepts of
the Other C. of C..

We can consider the Egyptian plastic following the presentation of the architect Fournier des Corats
in his book "The Egyptian Proportion or the reports of divine harmony". He was using the

folding of the faces of the pyramid on the base square. He finds 8 reports where the
name d'Or.

He analyzes Egyptian monuments, sculptures, paintings and easily incorporates them
in these reports.

2 Vega Editions.

© EÜRECALL

At first glance, this is not surprising when you know the conventional and stereotyped aspect of Egyptian art. There does not seem to be any error with respect to the bases of the proportions.

Naturally one can think that the noted inversions of eifs make doubt that we follow a right path.

This remark is something to be wary of. One cannot make of an inversion of a spectrum of eifs a dogma of harmfulness. We simply observe the inversion. The spectra at the EFF level come from analogies with a wave system; we left that analogy aside for him substitute an axiomatization. This, although it does not explain the historical approach, let's say the heuristic aspect, cannot erase this aspect which gave birth to the classification of the eifs, their distribution on the square or disc transmitters.

It must be understood that the arrangement of events is a process of creating what was called "waves of forms" and that "waves of forms" - now eifs - are the progenitor (G) of the sequence of events.

The sequence of events is a primer (A). We are thus faced with a system {A,G}.

Let's see before going further a new concept: the Equimsey.

d) L'Equimsev _____

This is an entirely new concept in human thought. Consider two forms F and F'.

F and F' will be said in equimsey (and we will write F IF') when they are linked to a third form by a trajectory - We have either F IF' or F'IF _____.

Take the Earth in its orbit; at the time of the equinoxes, it is in positions T and T' respectively in spring and autumn. The earth T when it is in T or in T' is in equimsey. Thus T(in T)=TIT' and T(in T')=TIT'.

\\

This is detected as soon as one becomes aware of what equimsey is. And if the Earth is not in T or in T there is no equimsey. It is for these positions that the duration of the day is equal to that of the night.

© EÜRECALL

We will indifferently say the earth T is in equimsey, that is to say that T is Tl T' or that T and T' are in equimsey. The same word signifies either a state or a tension between two forms.

In this case the curve is the portion of the helix - which is often reduced to the plane curve: the ellipse, by simplification - that the earth travels in a year.

In the field of forms, T equimsey will often intervene. It takes completely out of the C. of C. usual.

Let us consider in physics the system constituted by an object and its image obtained by reflection in a plane mirror.

Let us now apply the process - already used in the course of the 1st level - known as: transport of structure. We have seen that the concept of path is used for this.

object — $\ddot{y}$ ←—”image (by mirroring a plane)

Let's go back to this path that we apply to a form of the usual C. de C.; this will make existing the image concept of a being.

Let us take the observer on which we make this channel act.

the observer —→image of the observer

But let's look at something more general.

We are not going to consider the observer in the sense of physics, that is to say a human being linked to a system of reference points, but a human being representing himself doing operations of the kind moving in space, giving himself states, talking to himself or to other people, finally, more generally, the observer thinking and looking at himself thinking. This will constitute what we call the OBS.

Thus the obs is the observer thinking himself thinking.

Now consider the obs -3yla route.—→ Qn va appe ! er ce result the image of obs.

We will therefore have Obs —→QN—→ the image of the obs.

Of course the obs is little in the usual C. de C.; as for the Image of the obs, it is linked to the global.

Fields of Consciousness:

Consider obsImage of the obs: this equimsey is the consciousness of Lobs.

We talked about equimsey; however, the curve to which the two terms are attached has not been specified: obs and image of Lobs.

It can be any curve, continuous, discontinuous, closed or not, a fractal object...

And due to the fractal dimension which is, in general, not whole, we will enter the domain of surfaces, volumes, then vector spaces, affine spaces, Euclidean geometries, riemaniennes, projectives.

,Thus for each curve, each plane, more generally for each mathematical stmcture quoted above, we will have a "Face of the field of consciousness".

So we arrived at the concept of Field of Consciousness, which is quite different from the Field of Consistency.

The obs can extend the concept of consciousness to other human beings who are placed in his field of coherence (C. de C.) but it will always be only an extension of consciousness.

Consciousness now presents itself as a notion linked to the global, therefore as a notion which is not in the usual C. of C. but which belongs to the other C. of C.; she is in this like love, fidelity. These are notions about which we cannot impose any scale of measure.

This does not mean that all the other C. of C. is composed of notions without landmarks. In the other C. of C. we will find what we call Rays of Coherence (R. of C.) and Swarms of Consistency; in all these there will be "local" which is not the local of the usual C. de C..

More specifically, when we have the impression of finding concepts linked to the global in our C. of C., it will be a "trace" of the other C. of C. in the usual C. of C..

Consciousness as seen by psychologists is a distortion of the concept of consciousness as we have just established it. Their concept of consciousness is distorted to fit at increasingly intense localizations.

By immersing consciousness as a trace in the concept of field and by diluting this notion, we thus correctly constructs the "Field of Consciousness".

c) The Cheops pyramid (continued)

A and $\bar{A}$ primes
G are in equimsey [G progenitor

That is to say that we have: $A|G$.

It is the rational vision which, by means of a representation, gives the usual unfolding of events.

We would have the same thing in the following problem: it is that of the Extraterrestrials:

At some point we will discover extra-terrestrials - it will not be the antics of beings linked to the UFO phenomenon. For the UFO phenomenon, we develop it in the work of Jacques Ravatin and Anne-Marie Branca: "Theory of Forms and Coherence Fields (to be published in Editions du Cosmogone, during the year 1998).

So at some point extra-terrestrials will be discovered and this, we will say, in the usual C. de C., thanks to the discoveries of science; it will be consistent. In fact, scientific discoveries will have served as a ritual to discover extra-terrestrials; be A but the extra-terrestrials, themselves, are a partial localization of the world that engenders scientific discoveries, the evolution of humanity, let G. And again we have a system $\{A, G\}$ which will behave $A|G$.

One sees little by little by these two examples, that the succession of events does not present itself any more as in the usual point of view and that it takes on a different character.

© EUREECALL

By thought bring the edges of the pyramid of Cheops into the cardinal planes - which comes back to make a 45° rotation of this pyramid - (one can also work on a model), the spectrum of eifs will be distributed as follows:

UVÍe at the top

Go to the base

The equator becomes that of the tree trunk again.

This orientation was that of the Mesopotamian step pyramids at the top of which was to be built a temple.

Editing left as an exercise:

Put on a table

- 1) an elongated piece of wood, naturally polarized.
- 2) a small model of a pyramid similar to that of Cheops with a plane of edges in the extension of the axis of the piece of wood and the side of its positive end.
- 3) between the pyramid and the end of the drink, a copper or plastic ring placed on the pendulum so as to no longer find esav in the vicinity.

This little assembly can be used as a balancer. It can be made operational in a large volume by increasing the size of the various components. It will not intervene on harmful states.

Bélizal had attempted an association between the so-called Louksor shape - imagined by R. de Lafforest from the improperly called "Atlantean" ring -.

Belizal's error was to orient his pyramid like that of Cheops.

Otherwise we could get a pretty good rebalancer but only eifs.

Note: these mounts are far , as a rebalancer, of the quality of what we have offered in exercise.

**“Nature is a temple where living pillars sometimes leave
get out of confused words:
The man passes there through forests of symbols which observe him
with familiar looks. »**

Charles Baudelaire

(The evil flowers)

Charles Baudelaire: born in Paris on April 9, 1821. He studied well at the Royal College of Lyon, then at Louis-le Grand, he knew the poets Ernest Prarond and Gustave Le Vavas seur. He made a 10 month trip to India. On his return he meets Jeanne Duval. Later he meets Théodore de Banville, Sainte-Beuve, Théophile Gautier.

He writes "The Flowers of Evil".

He translates Edgar Poe.

He died on August 31, 1867.

I. *Cumulative - Decalary*

Let's start with an example: that of the straight railway line, made up of two parallel rails and parallel sleepers. The crosspieces may have unequal, unknown widths.

Let us place an observer, seated between the rails, with prohibition to move and counting the sleepers because it is his job to count the sleepers.

For him the two rails behave like Lobachevsky parallels meeting on the horizon line at the named point, by people who use perspective: the vanishing point.

The observer - we can speak of an observer because here it is an observer in the sense of physics - knows that the number of sleepers is finite but he will never be able to know this number for the reason following: towards the horizon the crosspieces seem to merge; and this from a certain moment and not from a certain number; hence the observer can no longer count them. It results that he cannot even estimate approximately; it's not vague, it's absolutely indeterminate; we are in the presence of a "decalaire".

Note that the same is true if the railway line is curved towards the horizon.

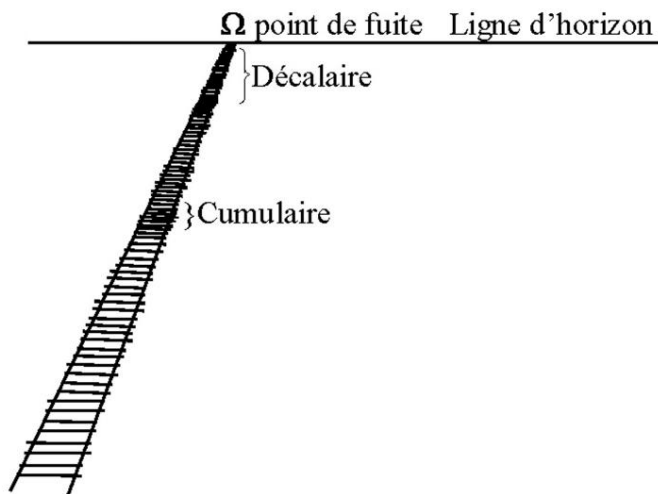

Another case may arise; without reaching the horizon, because the crosspieces are of widths unequal, we will no longer be able to count, from a certain point onwards, and the inaccuracies will be impossible to lift. And yet we can recount, pass this range, but announce what Name ?

We are in the presence of a "cumulative".

When the impression of a sequence appears in a set of numbers and this sequence will include cumulatives and a decalar, we will say that we are in the presence of cumulo-decalar.

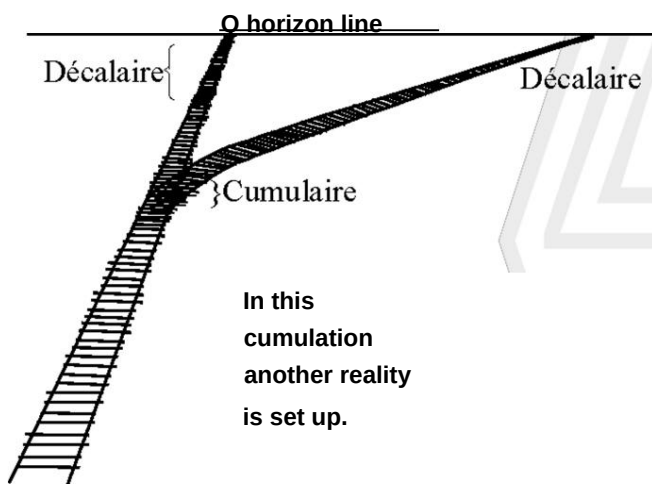

On the cumulative and decalar markers are on the run.

© EÜRECALL

Point Q responds to $|K Sh Ph\rangle$

Note that in these drawings
cumulatives and shifts have no
no sharp or fuzzy boundaries. He
we must speak of wandering.

In this
cumulation
another reality
is set up.

© EÜRECALL

An example of a shift can be found in the following old problem: the so-called "egg and the hen". It looks like this: in the evolution ^{To}, was it the egg that spawned the hen or, reciprocally, is it the hen that spawned the egg? In many congresses of scientists, in particular of biologists, this dilemma has been evoked many times seriously or as a joke, then he was forgotten each time. Everyone was trying to lift the alternative.

This problem is interesting to present in view of the points of view developed in this course because we finds in the presence of a recursive system: egg - hen - egg... If we consider the point of view rationally, we go up the scale following this simple recurrence punctuated by another scale; the system 1-23 4.

Note the Theory of Evolution.

We find ourselves in the typical case of a phenomenon described on a time scale of 10,000 years, 30,000 years, 100,000 years. We can even go back to the tertiary era because the thought rational carries much further forward on this scale.

If we pose this egg-chicken problem according to the concepts developed here, which belong to the other C. of C. but which we are going to apply to the usual C. of C. to which we are going to give another representation by these new concepts - we impregnate it with these concepts - the egg-chicken system emerges from a shifty. So there is no hen created first laying an egg or egg first spawning a hen.

The usual C. of C. appears different according to the type of thought used; this leads to representations different. Thus by these new concepts the rational C. of C. appears closer to the other C. of C., less foreign. It is therefore necessary, when speaking of a C. de C., and especially of the usual C. de C., to mean the type of representation chosen to describe it.

3 "The Theory of Evolution" is constructed from the usual time scale.

4 The 1-2 system will generate the sequence 1,2, 1,2, 1...

Let us give ourselves a series of stakes, planted in the ground, protruding from the ground by a certain height; all these stakes are placed in the same plane. For an observer who stands up, placing these stakes in his gaze, and this for certain positions, these stakes appear on the landscape as perhaps preceding the landscape. The landscape and the series of stakes can create for this observer a decalar which, as we said, is related to the position of the observer. This could be used by the Ancients to produce effects.

The writer Maurice Clavel gives a physical sensation of flight on a cumulative [1]. He writes this: "So it was lightning... Should I say lightning, if I didn't hear anything. But those who are taken in do they hear its crash?... I'm not even sure that I saw the lightning. I was on the couch. I was lifted, thrown away, crushed. At least I had the feeling, but without any representation, as if everything happened in an indivisible time and space. I would be lying if I was talking about a transport and from a distance... (.....) I saw nothing but the night and heard nothing but the silence: a night, a silence distinct from all the others by the relation of the infinite to the finite. Two states mingled, without destroying oneself, without even harming oneself, may be recognized as bliss and terror. I even knew that it was a blow struck by the Father. Of what knowledge, I do not know. But I haven't quite lost consciousness, this detailed memory attests to it. And I even felt, as if there was also a duration, sunk indefinitely in this night and in this silence... (.....) And I don't think I'm glorify with grace. Because it is one, certainly, but modest and current... ".

Maurice Clavel describes a feeling close to a cumulative. Some will consider it and will classify in what is commonly called, a loss of consciousness. There is actually a disturbance of consciousness in the rational view of things but in this lived example, one can feel the inaccuracy of spotting that characterizes the approach of cumulative decals. La description is clarified after the fact, but the memory has kept the imprint of the flight of landmarks usual.

The shifter passes from the local to the global, and reciprocally the global flows through the shifter. We cannot observe the global. It breaks, flows through the decalaires and cumulaires.

© EÜREECALL

The forms which are in the usual place, according to the usual point of view are immersed in the structure space-time. From what is developed above, we rethink the rational C. of C.; he is like seen from !, exterior.

II. Canal

Another concept was necessary: it is that of *Canal*. The Channel is the passage from the local to the global and vice versa, but this passage is not made according to a counting scale.

The plural of canal is the usual plural or canals.

The channel is completely delocalized.

The term Décalaire was created by Bernard Vivès around the 1960s. J. Ravatin created a term similar at about the same time, without knowing B. Vivès: it is a question of the word "Cumulaire". terms designate the escape of cues. With the decalaire we are faced with a definitive flight of landmarks ; in the case of the cumulative flight is followed by a catch-up of the landmarks. Note that the definition of the decalaire of B.Vivès was only of mathematical order. Now in our research work a very deep physical sense has set in but it is about physical which are not those of the C.de C.rationnel. You should also know that the gravitational attraction black holes looks like leaking landmarks.

Course
2nd level
Paper 15

March 98

I. Complements on pyramid shapes

We will use the folding of the triangles of faces of the Cheops pyramid on the square base.

Consider, for this, the base ABCD and the top S of the pyramid with $AD = 2$ and the height $HS =$

Let us fold the edge AS on the diagonal AC, following AM.

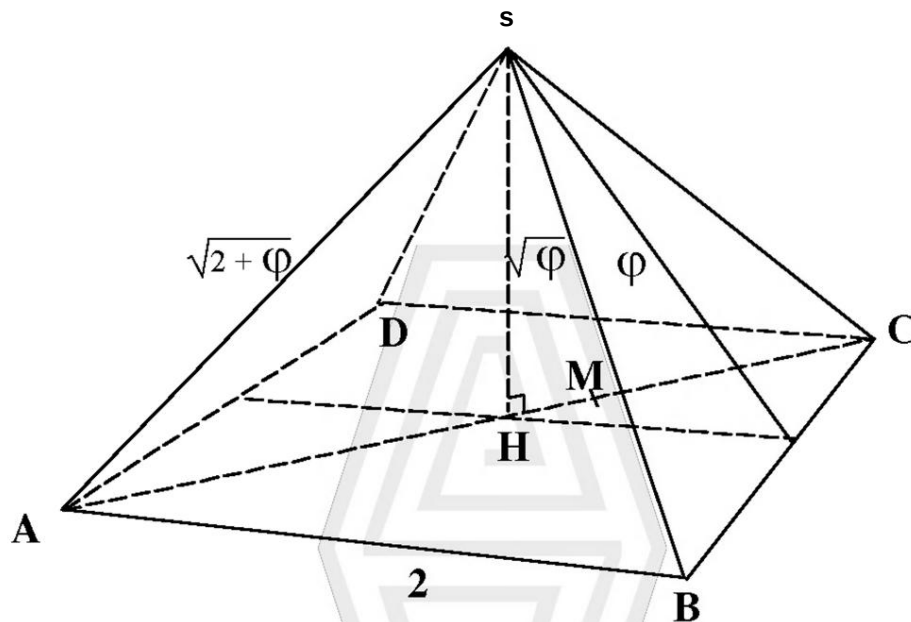

$$AS = \sqrt{2 + \phi} \approx 1,902$$

$$AC = 2\sqrt{2} = 2,828 \dots$$

$$AM = AS \cdot \frac{1,902}{2,828}$$

$$AC - AM = 2,828 - 0,672$$

$$\text{Or } 0,666 = \frac{2}{3} \dots$$

La différence $0,672 - 0,666 = 0,006$ ce qui fait une erreur relative de $\frac{6}{672} \approx 8,928 \cdot 10^{-3}$ soit 0,009 soit 0,9 %

For the Ancients such an error was negligible in the realization of forms even if it is a question of the Cheops pyramid to scale 1. Knowing the length of AS, it is easy to calculate AM by

2 replacing the ratio 0.672 by 0.666. The fraction $\frac{1}{3}$ (so $\frac{2}{3}$ appears) will be very useful for the following

and we will see that we can take for 7C: 3.2; it will be very correct in the constructions.

Remark : _____

One can wonder what relative error one can take to confuse lengths or at the
on the contrary, two lengths 1 and T correspond to different shapes F and F' as
as emissions, states, etc.

H--- 1-

yl

F F'

For this, consider the half-line of positive numbers that will serve us
scale to carry relative errors.

So in P we will have an error 2

in P' we will have an error Z'.

If we ask ourselves the question of knowing, by making Z' tend towards Z, for what value of Z' the 2
forms F and F' could be considered as identical, one completely denatures the
phenomenon.

Here we are between P and P', not on segment 1----- \ but there is a leak of markers
between P and P' which is due to the very existence of the eifs associated with F and F'.

It is necessary to pay great attention to the stability of the scales according to the phenomena to which they relate.
report.

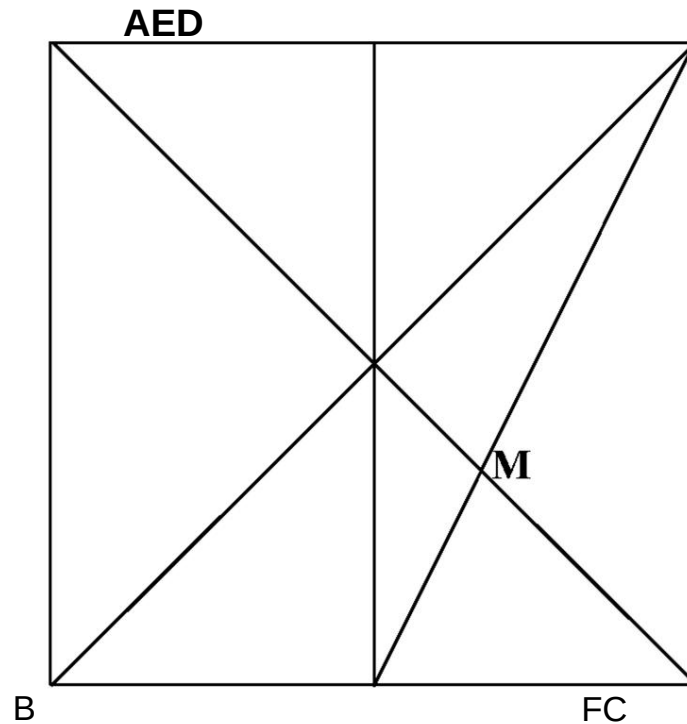

Return to the pyramid: We can therefore very well build a pyramid whose edge is exactly

2 equal to the $\sqrt{2}$ of the diagonal of the base square.

The properties will not be altered in any way. Geometric constructions will be found
greatly simplified.

Let's see a simple geometric construction to obtain the folding of the edge on the diagonal
of the square.

© EÜRECALL

Let's go back to square ABCD. Draw the line passing through the midpoints E and F of AB and DC respectively.

We get two equal rectangles with sides proportional to 2 and 1, which is called in language traditional "Silver Squares".

The diagonal AC of the square intersects in M the diagonal DF of the rectangle EDCF

The 2 triangles AMB and CMF have their angles equal; they are therefore similar; this allows to describe :

AWAY $\frac{AM}{FC} = \frac{1}{2}$, $\frac{AM}{FC} = \frac{1}{2}$.
 FC CM 1 d ou AM 3A C

II. *The Saying of the Companions*

From the traditional tables of the Compagnons, we only know the "Said". The word Table means here a closed planar shape. To return to the said, it is stated as follows:

"The Grail rests on 3 Tables of equal surface, one round, one square, one rectangular and their Number is twenty-one".

"A fourth Table covers them and its Number is six".

"The Grail is seventeen and he is one".

It is both a mnemonic device and a symbolic text. So when we say: "The Graal is seventeen and it is a "you don't have to think 17 times a unit. let's see a interpretation by J. de la Fôye. He supposed the Grail to be a Square Table and so he thought for his side: 7. Which gives for diagonal $\sqrt{98} \sim 9.9$, graphically close to 10. Hence 10 and 7 is 10 - 7 (seventeen). 10 instead of 9.9 is sufficient for a layout.

In this square, as we did for the undifferentiated spectra emitting plate (EFF) and differentiated, we draw the inscribed equilateral triangles.

Let us orient the "Grail" with its diagonals NS and EO like the pyramid of Cheops.

Join the midpoints of the sides of the square with straight lines. We form rectangles of which we draw the diagonals.

Each cuts a diagonal of the square at a point one-third the length of the half-diagonal from the center of symmetry of the square.

The intersections are the vertices of a square homothetic of the original square, the ratio of homothety is $\frac{1}{3}$.

Interpretation:

This square will be considered as the Square Table of Companions from which we will deduce the two others: the rectangular and the round.

A question arises for the Round Table: it is a circle whose center will be at the center of the Square table but in its surface intervenes TC which is a transcendent number. But the Elders only used whole or fractional numbers.

An approximate value of TC will therefore be used. Let us point out that further we go into a note discuss this issue of TC values.

We will be interested in the intersections of the Round and Square Tables and by symmetry only one intersection enough.

So we are going to operate a redivision in two on the side of the Square Table - which perhaps justifies the number 21 ie 2 and 1-.

But this number can just as easily derive its significance from the proportions of the rectangular Table as of the fundamental method of construction, or simply mean as does notice J. de la Fôye, that the Tables increase or decrease according to 2^n . But let's go further

the Grail and the Tables can cover the plane from a center by homotheties of this center gear 3.

The eifs that are issued: VC, FV, and the 4 lfs, then TAVAECUM. Moreover it is linked to the Idathème as well as at the Global - All this as soon as we considered the Grail Table as a new Table square of the Companions which will immediately draw the homothetics into this same relation of the Round and rectangular tables.

Note that in the powers of 3, $3n$, the larger n is, the larger the Tables are and the greater the approximate value of 7C risks bringing a non-negligible error on the surface of the circle.

But starting from a circle with a fairly small radius, about 1 meter, we can make homotheties of ratio 3, 32, 33 ; these are enough, to generate a figure which will have properties remarkable although the circle of radius 27 m will have an area whose difference with the area where we would have taken 7C, will not be negligible.

Let AB be the side of the square Table that Ton will take equal to 4.K midpoint of AD.

Let's take L such that KL = 1 on AD and OL = $\frac{\sqrt{5}}{2}$ then KO = 2.

The area of the square is 16.

Consider the circle of radius OL.

Its area is: $7C \times 5 \sim 15.708$

Let's see the difference $16 - 15.708 = 0.292$

What makes a relative error: $x 100 = \frac{0.292}{1.825}$

i.e. 1.86%

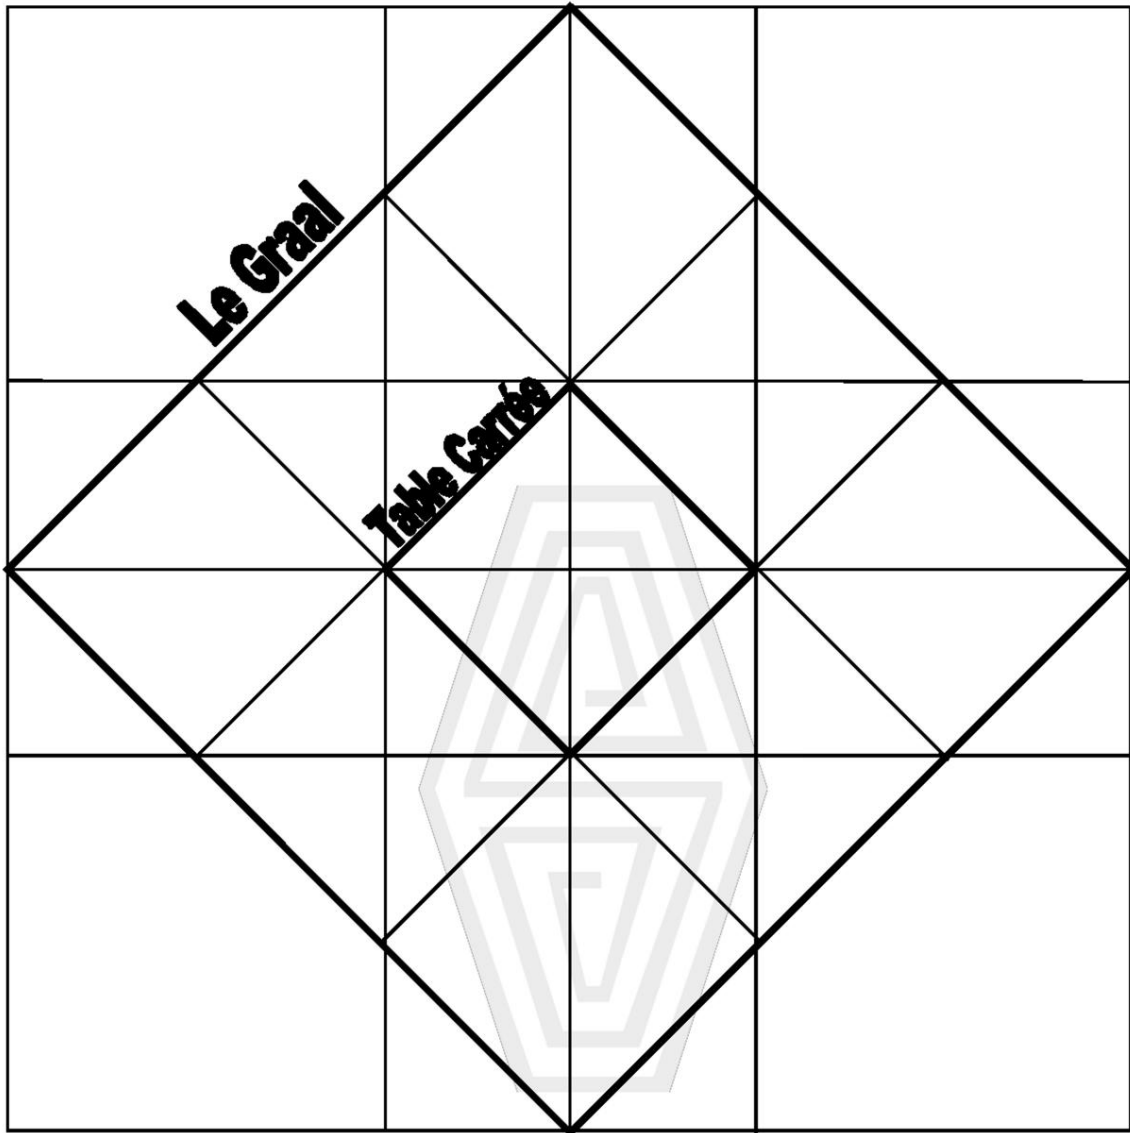

This is not negligible.

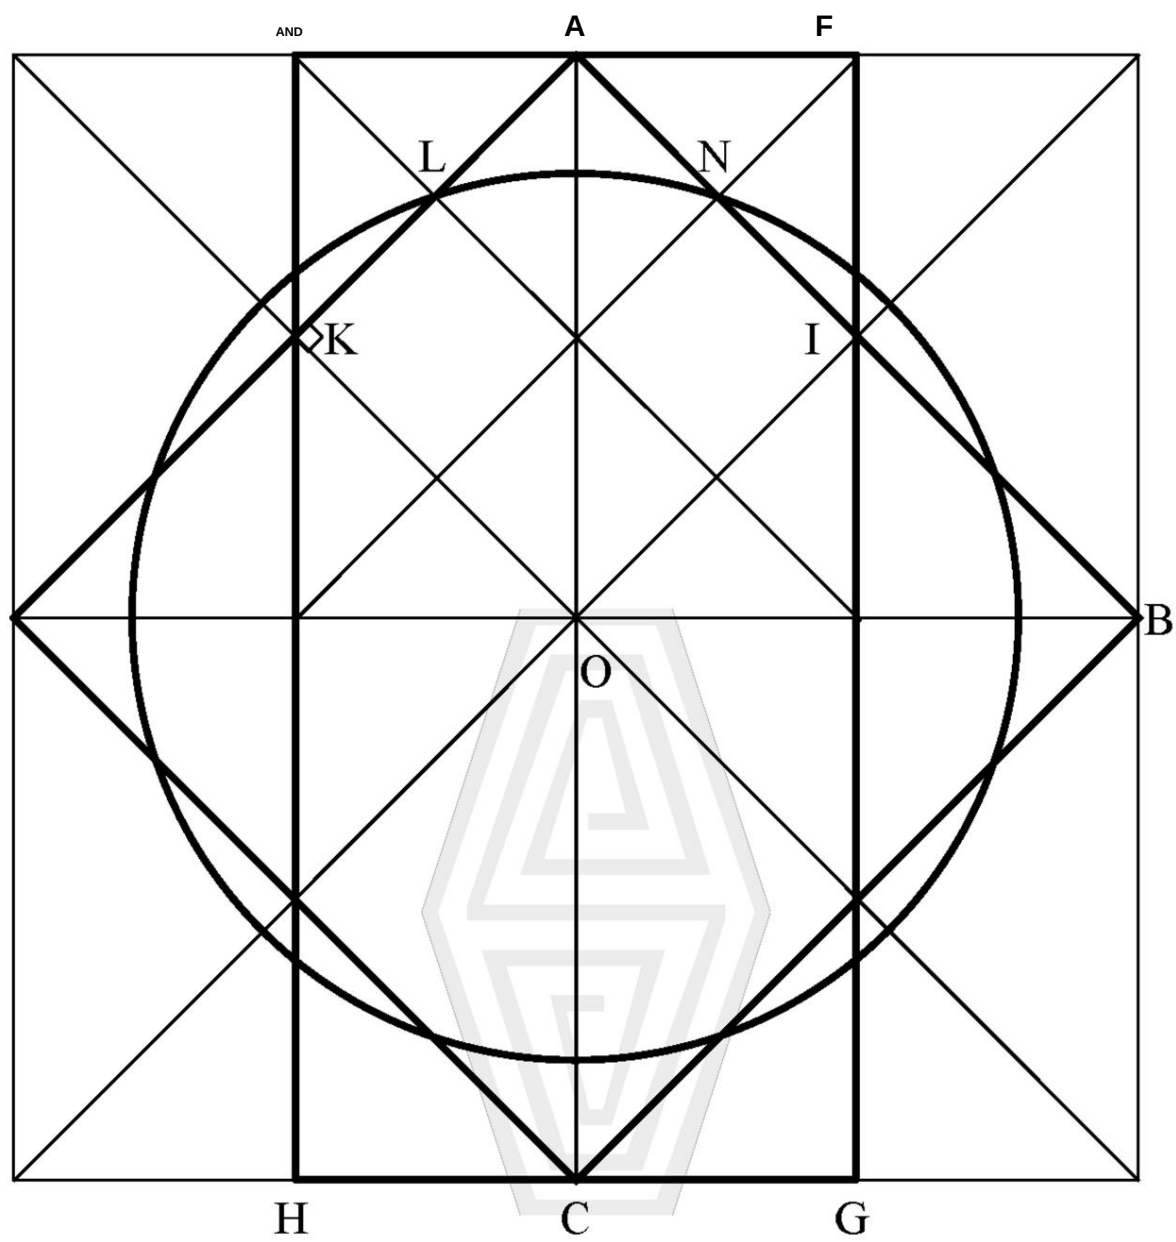

This also amounts to taking as the surface of the circle $7C'R^2$ where $71' = 3.2$, which the Ancients could quite consider: The relative error is: 1.87%.

If $7CR^2$ (where R is the radius of the circle) = 16

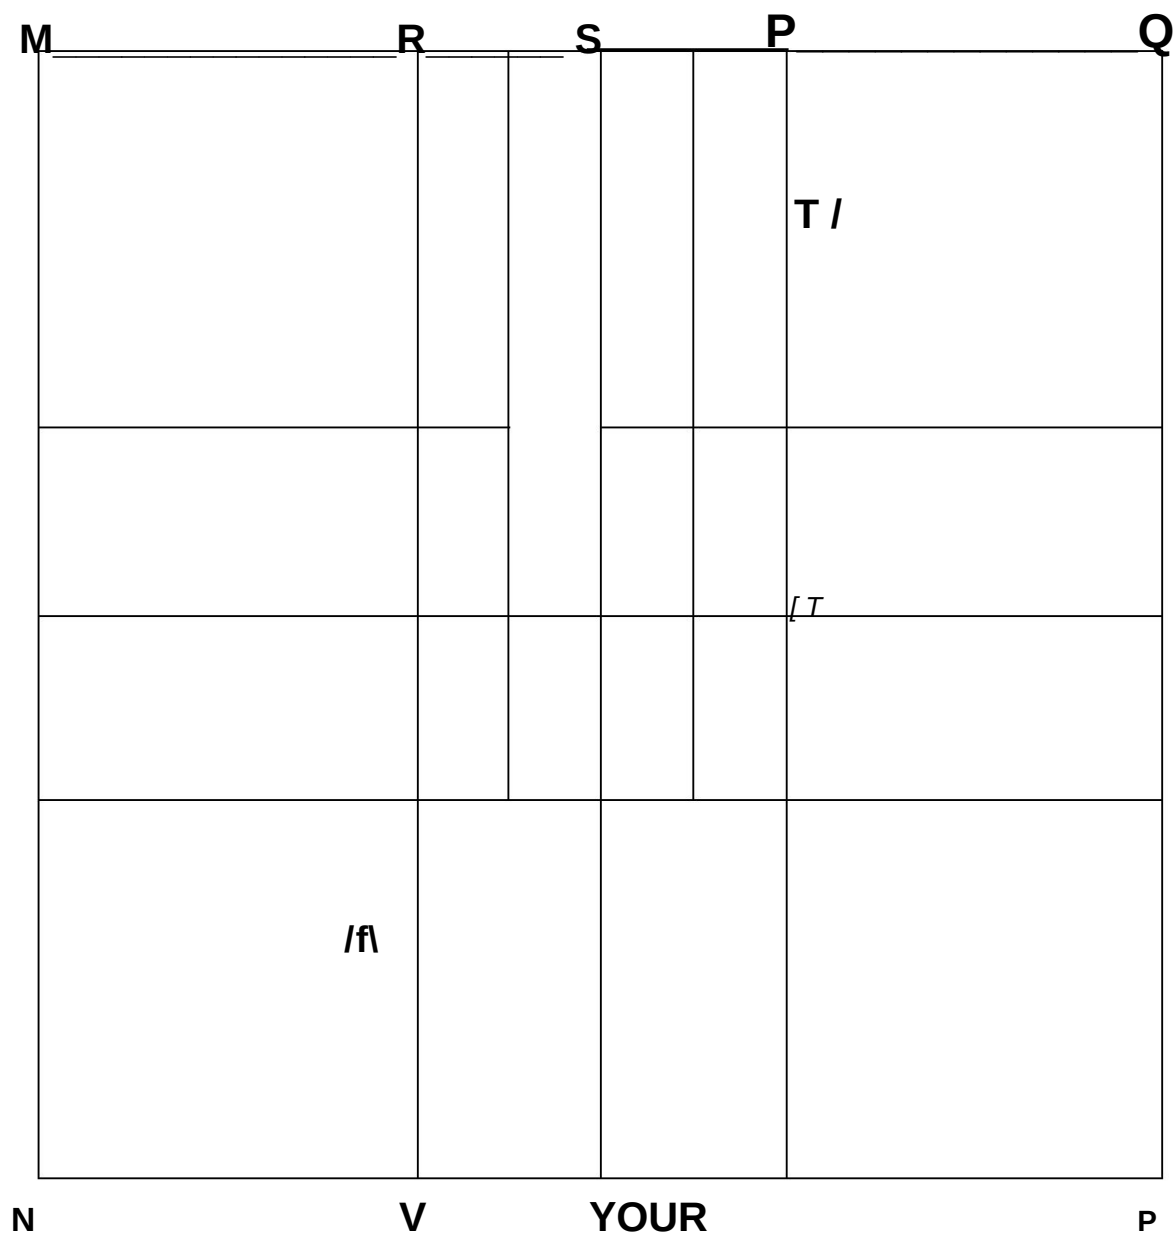

With $7C \sim 3.14$, we derive $R \sim 2.257$ whereas we had taken $R = \sqrt{5} \sim 2.236$ from which $2.257 - 2.236 = 0.021$

For KL=4cm, it is acceptable.

The Three Tables

Draw a square MNPQ

Let S, T, U, V be the midpoints of the sides as in the figure.

Let's draw the STUV square

Let E, F, G, H be the midpoints of the sides of this square. This square will be considered as the Grail.

SF intersects EU at K. By symmetry around TV, K is on TV.

Let L be the symmetric of K .

From Homothety with center S and ratio $\frac{1}{3}$ we get that $KL = 2KO = \frac{2}{3} TV$

So the perpendiculars to TV in KL intersect NQ in R and P such that $MR = RP = PQ = \frac{1}{3} TV$

By rotation of 90° around O we obtain an equal division of MN .

By rotating 90° , we get I, H from K, L .

The figure $HKIL$ is a dilation square of the square of the Grail, in a dilation of center O and of

ratio $\frac{1}{3}$.

PL intersects SV in T . The KHT points are aligned by parallel projections which preserve the ratios.

We can easily draw the Rectangular Table and the Circular Table taking into account the remark above, that is to say for 71 we take 3.2 which on this scale is quite acceptable.

Let G be the midpoint of rectangle $RKOS$. One side of the Rectangular Table passes through G and the points $RGOW$ are aligned.

RW cuts HK in Z .

By homothety of center H and ratio $\frac{1}{3}$ which brings the line EU on the line RW , we get that

$HZ = \frac{1}{3} HK$ so that OZ is the radius of the Circular Table.

From G as center let us draw an arc of a circle radius EG , ie the length of the side of the Grail.

It cuts SV in Z and TU in F .

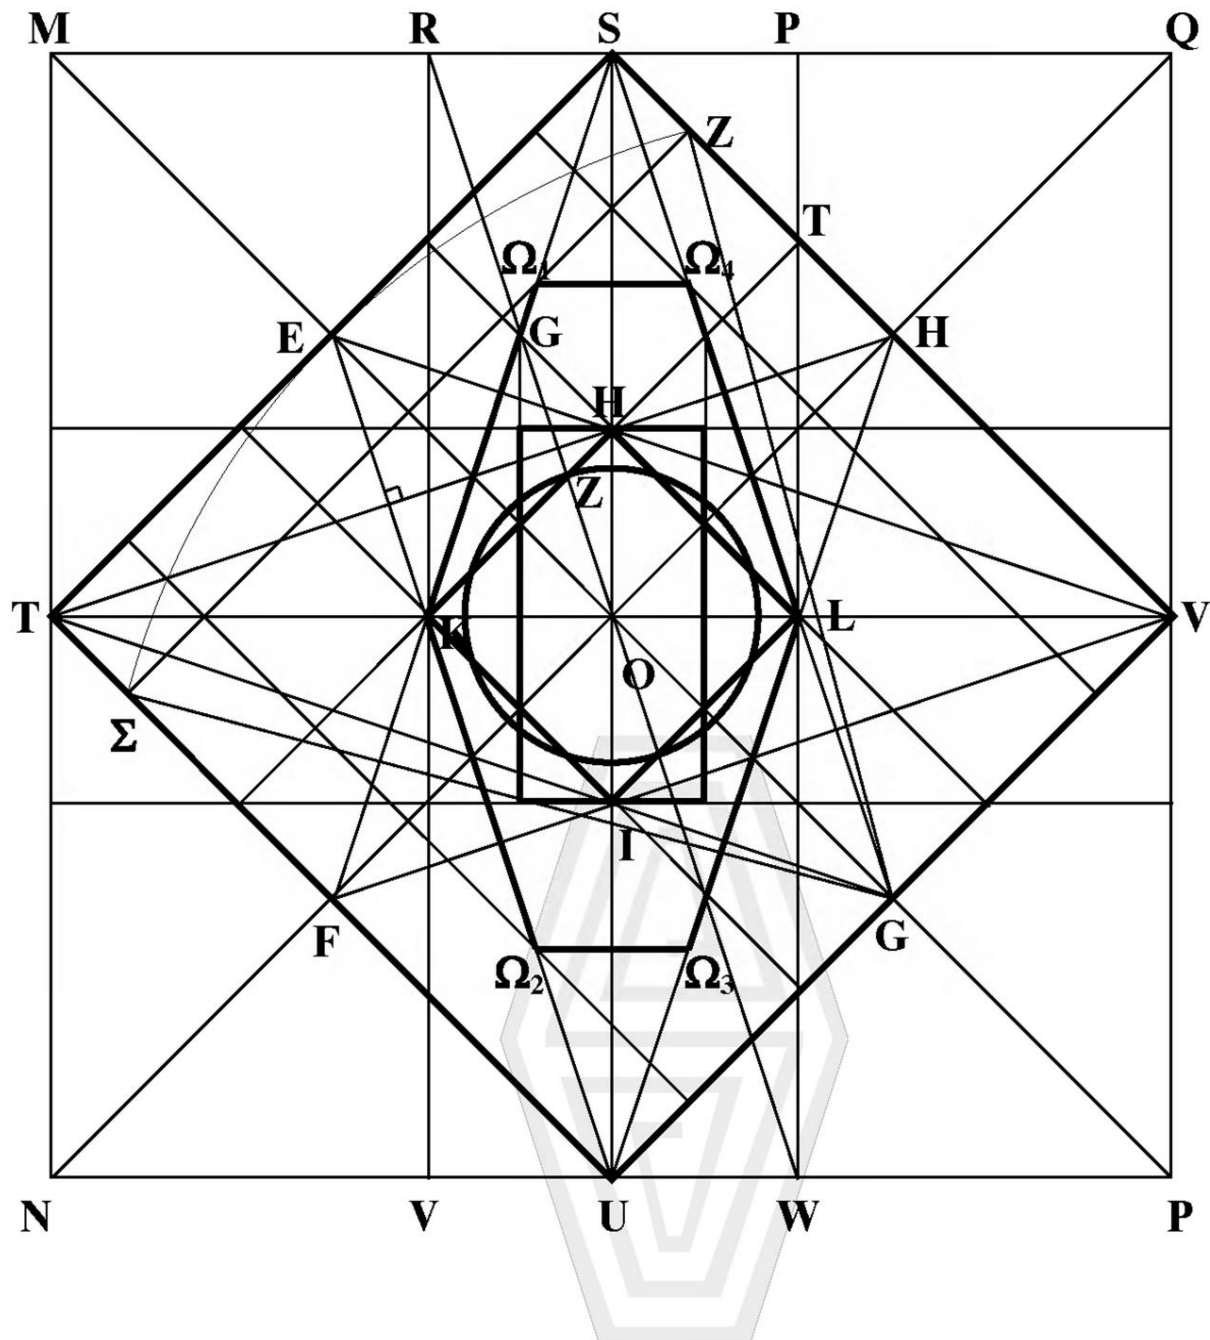

ZF is the side of one of the equilateral triangles inscribed in the square. We find the building starting point of the transmitter square - course of the 1st level -.

It is indeed these equilateral triangles inscribed in a square which made it possible to draw the figures generating the eifs at the EFF level. Care must be taken not to confuse the Square Table with the square of the undifferentiated spectrum.

The SKUL diamond will serve as a support for the 41st Table. One of its diagonals is that of the Grail, the other diagonal is that of the Square Table.

What is said about him?

"The fourth Table covers them - The 3 Tables - and its Number is 6".

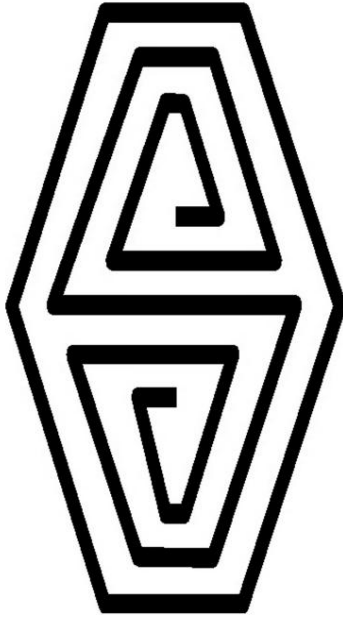

© EÜREECALL

It is perhaps not the surface which is 6 although one can think of it because the diagonals of this
£
rhombus are in the ratio 3 to 1. Taking 2 for the smallest, the area is $2 \times 6 = 12$.

But there is better: 6 will be considered as the number of sides. The fourth Table is therefore a hexagon but not regular.

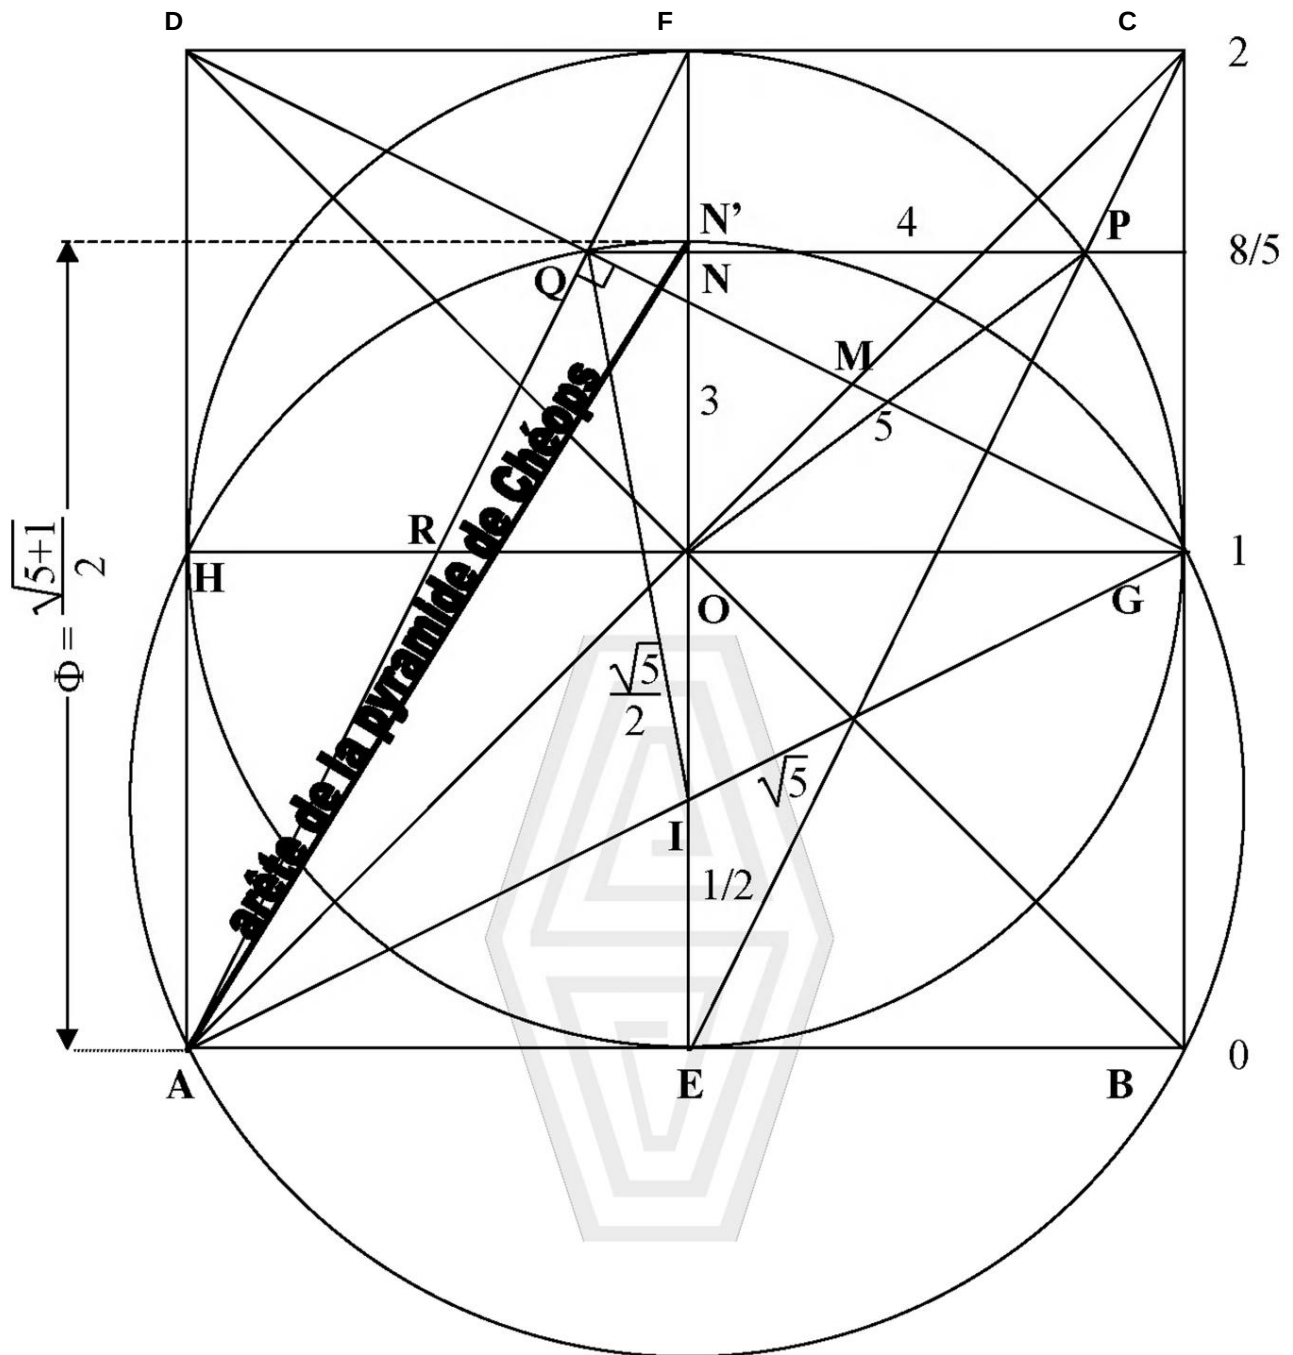

SK coupe ZZ and Q! † By symmetry we obtain the points $Q_2, ^3, ^4$: $Q_1, KQ_2^3LQ_4$ is the hexagon look for.

IDALAB <S>

We find the external form containing the double
labyrinth and the whole constituting the named form
IDALAB which is reproduced on each page of these
booklets.

To come back to the Said of the Companions it is necessary to
see as the mnemonic expression of a
geometric process.

© EÜREECALL

The Grail and the 4 Tables are not materially part of the Cheops pyramid.

They are perhaps only an invisible framework recalling the orientation of the monument which imposes its edges in the cardinal planes.

The monument will have its general lines along the NS, EO and vertical.

The construction that we have just exposed makes it possible to find the pyramid of Cheops. So we're going use again the Golden Number ϕ but it is not in general a number which involves balanced constructions.

If you want good proportions you have to use the number Radiant $\sqrt{5}$.

Let square ABCD be the base of the Cheops pyramid. The drawdown of M on the diagonal AC of the vertex of the pyramid with edge equal to $\frac{1}{2}$ of AC - We saw that it was reasonable to take this ratio - is obtained by the intersection of the diagonal AC with the diagonal DG of the rectangle CDHG.

The folding of the vertex S around AB as a hinge is done in N.

The circle with center A and radius AM intersects EF at N'. AF and DG intersect perpendicularly in Q

AG intersects EF in I. From I as center, let us draw the circle circumscribed to the right-angled triangle AQC. He intersects EF in N because if the side of the square ABCD is equal to 2

$$AG = \sqrt{5} \text{ and } IA = IG = IQ = IN' = \frac{1}{2}$$

$$EI = x \text{ therefore } EN' = IN' + EI = \frac{1}{2} + x = IN$$

This does not mean that the Egyptians took $\sqrt{5}$ in all their ratios and proportions contrary to what Fournier des Corats had found

III. Conclusion

The Radiant number was not used in the drawing of the 3 + 1 Tables and the Grail. But if we put on the 3 tables, covered by the fourth, hexagonal, and the whole covered by the Grail or placed on the Grail, a form associated with the Radiant number, so in some cases it is linked to Tldathème, to the Global a whole area of ET. Moreover we detect the fields Z, ZD and the P-Fields - we already have noted that these will not be covered in the 21st level course; we can refer to the work of Jacques RAVATIN and Anne-Marie BRANCA "Forms and Coherence" Editions: Le Cosmogone.

perfect. »

Leonardo DeVinci

Leonardo da Vinci: born April 15, 1452 near Florence, famous painter of the Florentine school, who was also a sculptor, architect, engineer, mathematician, writer and musician. Natural son of a notary and a peasant, he was nevertheless raised in the paternal family. His father brought him into Verrocchio's studio in 1469, where he became friends with Perugino and especially with Botticelli. Many of his works have been lost. He was under the orders of César Borgia, a military engineer.

He made the portrait of Mona Lisa called La Joconde around 1503-1506.

He painted the Last Supper for the Dominican convent of Sainte-Marie-des-Grâces (1496-1498).

He was, as P. Valéry said, “what could look at the same spectacle or the same object, sometimes as a painter would have looked at it and sometimes as a naturalist, sometimes like a physicist and other times like a poet. »

Let us mention his “Treatise on painting”, illustrated with drawings, in which he studied the theoretical principles of this art, and which will be admired by Nicolas Poussin.

He had invented a lute.

Leonardo da Vinci died on May 2, 1519 at Clos-lucé (near Amboise) in the arms of his pupil, Francisco Melzi.

Exercise :

Lay a flashlight on its side so that the axis of the light beam is approximately nearly parallel to the plane of the table.

We manage so that this axis coincides as best as possible with a straight line drawn beforehand without take into account the cardinal directions.

A sharpened pencil, placed on the table, is oriented in the luminous flux.

1) Check that the eifs are detected perpendicular to the axis of the luminous flux and that their color depends on the angle of the pencil with this axis.

2) Check that this is the spectrum of the aura.

3) The perpendicular with the axis of the luminous flux constitutes the N_f , S_f

The axis of the luminous flux constitutes the O_f , the E_f

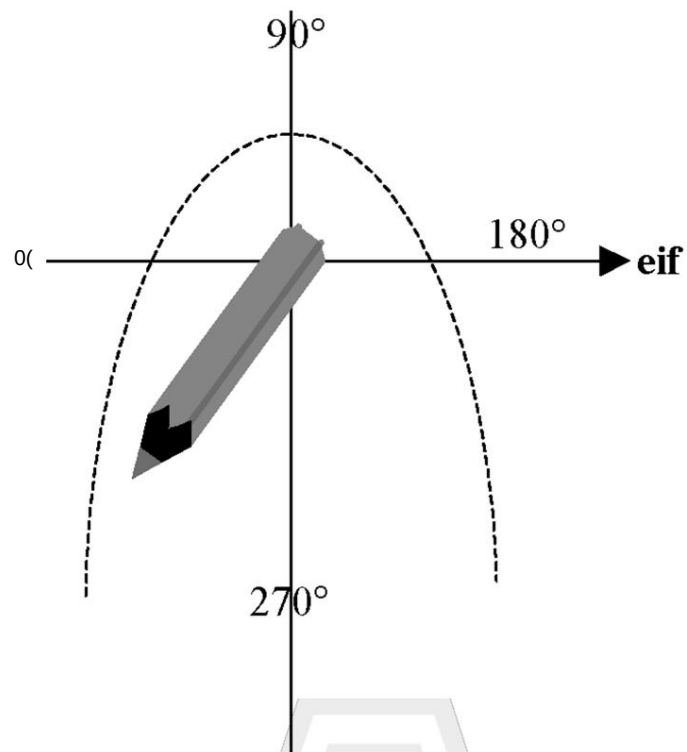

4) Check that the

a) pencil with tip towards the lamp emits the V_e detected at N_p , S_f

b) the pencil with point opposite the lamp gives V_m

© EÜRECALL

Flash light

Remark :

You have to be careful not to rotate the pencil n times 360° because this generates states specials, other eifs that may not be at EFF level.

L Amorce - Progenitor

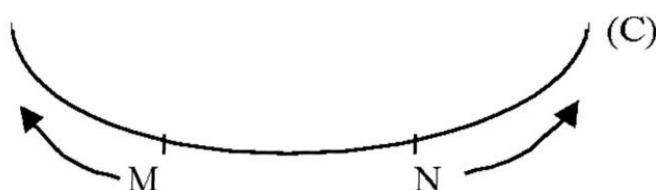

This presentation does not correspond at all to what we are used to encountering in the field .

rational where the search for details does not lead to loss of information.

It would seem that from the new point of view that we are developing, the search for details is only effects of catching up with leaks, these being erased according to the type of thought.

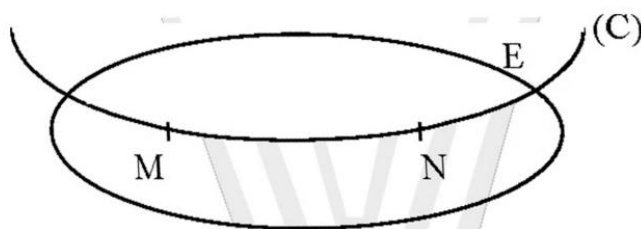

Give us a curve (C) in a plane P. The examination of a *phenomenon, of an event, will* match the set up:

- of a plane curve
- two points M and N on this curve
- movements of M to the left and of N to the right.

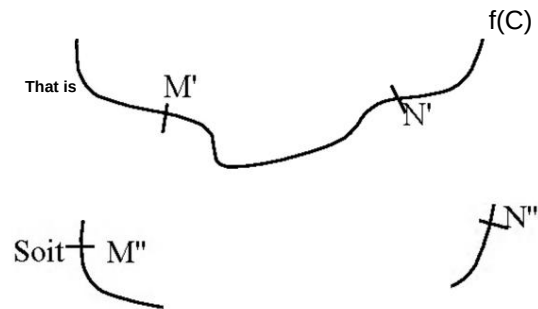

We talked about details. Looking and going into detail will revert to moving M left and N to the right.

- But we go further in the sense that giving oneself MN and (C) is also putting in place $\{M, N\} \cap (C) = E$ where E is a domain, imperfectly delimited, but nevertheless closed; that's about all we know about him; his frontier is on the run.
M and N are in E

- Immediately, we see that in this partial model of thought - because it is indeed a model - the plane P is not quite a plane of Euclidean geometry. The equimsey between the couple $\{M, N\}$ and the curve (C) gives it other characters. Thus, as there is leakage from the edge of the domain, talking about distance in neighborhoods of this leak is wrong make it possible to apply measures in these neighbourhoods.
- The progressive distancing of M and N will lead to a deformation of (C).

© EÜRECALL

(C) disappears locally between M and N. The "hole" that forms in (C) has even leaks so it has no ends on (C).

- The obs wants to enrich its model, its knowledge for a more in-depth study; so he wants to impose that he always has a curve such that (C). His intention will put place a new curve (C).

In E we can place other events, other curves bearing pairs of points. E will be always an equimsey between its pairs of points carried by these curves.

But E is not clearly defined; there is leakage on the border therefore the equimseys indicated above, will give domains that we can confuse with E "up to the escape".

We will therefore confuse the domains except for the leak.

, Thus we can ensure that any pair of points of E and any curve passing through these points are in equimsey and that the equimsey is E.

Couples of points can be found in the flight from the frontier of E. What will be said of them? They will no longer be well located, nor will the curve passing through them. So we can no longer talk about points and portion of curve, everything is on the run. We will therefore have the leak in the leak.

Conclusion :

We come back to the concept of examination, of becoming aware of a phenomenon, of a story. That is expressed by a displacement on a curve (C).

So :

(C) and {M,N} are given

gradually move away from each other.

this models

the organization of reasoning

- (C) is as in E, but very little outside of E;

- The "outside" of E is not known.

Definitions:

(C) is an OPEN FORM.

(C) is said PROGENER of {M,N}.

{M,N} is said to be PRIMER of (C).

In these same definitions {M,N} and (C) are not separable.

M changes to M' then to M''

N changes to N' then to N''; placing M''N'' on a curve (C) means that

$$I(C) = E'.$$

E' is a runaway boundary domain, in plane P.

E, E' enters into the elaboration of what we call a FOLIAGE.

So we act in a plan, plan P.

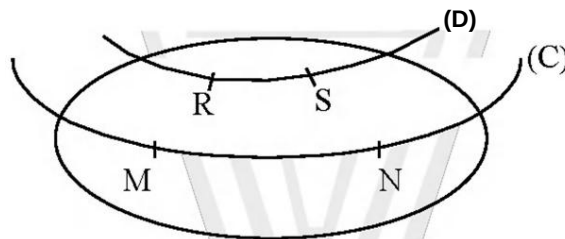

We see that the obs develops two dimensions.

The set of domains {E, E', E'', E''',...} will constitute a neighborhood of the obs in 3 dimensions.

The deformation of (C) then the leaks which arise between M' and N' are due to the impossibility of obs not being able to encompass (C) in its entirety.

The obs is aware of (C) but cannot represent (C) as a whole. This is what characterizes the open forms

Let's see the event {{R, S}, (D)} in E.

We have seen {M'',N''} I (C) = E' up to the escape

$$\begin{aligned} \text{Gr } MN \ddot{y}\ddot{y} < M''N'' & \Rightarrow E - \gg E' \\ (C) \longrightarrow (C) & . \end{aligned}$$

and (D) $\ddot{y}\ddot{y} \ddot{y}$ < D' curve such that if

$$\{R, S\} \longrightarrow \{R', S'\} \longrightarrow \{R\ddot{y}, S''\}$$

then $\{R'', S''\} \mid (C) = E'$

Thus $\{\{R, S\}, (D)\}$ is not a primordial, dominating event since $\{M, N\} \mid (C) = E$ and

$\{R, S\} \mid (C) = E$

Consequences :

We have just put in place a kind of reverse of what surrounds us. It is a necessity of cerebral process which is expressed formalized by the model. She's not the only one.

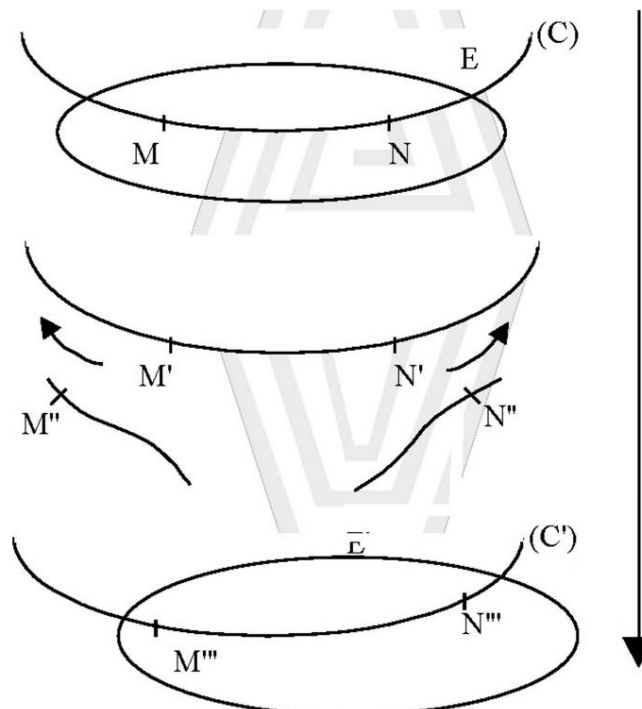

The foliation, i.e. the set of $E, E', E'' \dots$ will constitute a neighborhood of the obs, neighborhood 3 dimensional.

This is reminiscent of how a story unfolds when you read a book page after page. Skip a page to the next one is the equivalent of catching up the curve (C) by the curve (C'), then (C'')... The story starts in E.

If we only had E, it would be dull, with no follow-up.

With $E, E', E'' \dots$ the leafing, everything happens as if we had placed theater sets in which no play is played. There are only piles of stories.

The domains $E, E', E'' \dots$ are filled with intentions.

II. *The concept of time*

The transition from (C) to (C) sets time.

Time is going to be the attempt to rebuild the curve.

The displacements of M and N correspond to intentions.

Thus the foliage creates time and imposes a relationship of order.

The setting up of the foliation seems to require time, since there is a before E and an after E', one before E' and one after E'.

This is where you have to think differently and go further in the construction of the model.

To obtain the equivalences E, E', E'',... it is necessary to start from a curve. It is the same for all equimseys. It is closed and will serve as a support for attempts to reconstruct the curves (C), (C'), (C''), ... An attempt will consist of traversing the closed curve. Every attempt will be a course of this curve by obs.

Remark :

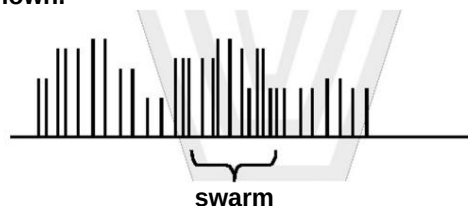

It should be noted that the obs considered here only exists through these leafing actions.

The realizations of foliations express the obs as he realizes these foliations. He is not separable from them. So we cannot speak of a time before the time that will generate them. It's not not at all Dunne's vision of time which is a recursive construct.

We are gradually entering a domain where we cannot define an entity. It is often necessary to associate it with a other and combine them by a process which is not in the usual C. of C..

Foliage and swarm:

A swarm develops in the ordered set of layers that constitute the foliation. The number of domains of the swarm is not known.

This swarm moves like a cursor over the ordered set.

Thus the intention of the obs discovers 3 faces:

- (i) M and N move.

(ii) (C) is rebuilt following (C).

(iii) The swarm and its movement.

The swarm constitutes what for the obs is a story or a set of stories that can be unfold simultaneously.

The movement of the swarm is based on the continuity of time.

The form, the event are put in place by all the sheets.

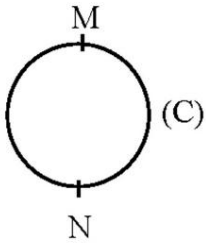

Irregularities are likely to form in the lamination: sheets may flatten on top of each other which affects the understanding of the story(s).

It can also happen that a swarm leaves its foliation to be replaced by a swarm which belongs to the foliation of another human being - the other human being constitutes what is called a DENSIFICATION POINT of the obs -. So the obs has stories that are not his.

It is one of the faces of what some call Reincarnation. She has many faces but it is not the fact of having already lived.

Swarms between that of the obs and that of one of its densification points can come into transfer. This is also another face of reincarnation.

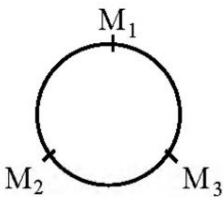

Suppose the curve (C), in the plane P, closed; take it as a circle.

If the plane P has the properties:

- (i) $\{M, N\}$ primer of (C) (Am for primer).
- (ii) (C) progenitor of $\{M, N\}$ (Gen for parent).

Then $\{M, N\} \mid (C)$ is the whole plane P, and this because (C) is closed.

Suppose three points M_1, M_2, M_3 on (C) such that:

- (i) $\{M_1, M_2, M_3\} = \text{Am } (C)$.
- (ii) (C) = Gene $\{M_1, M_2, M_3\}$

Then $\{M_1, M_2, M_3\} \mid (C)$ is the whole plane P and this because (C) is closed.

EUREK'ALL

I. Uauréolaire

1) Consistency

The human being, when he thinks, relates to Coherence.

The meaning behind this word is very subtle. It emerges in the form of an echo in the usual language where we speak of the coherences of each scientific field such as physics, chemistry - exact sciences, then biology, medicine, meteorology, etc.

The coherences seem multiple in our modern world.

But we are not talking about these coherences but about Coherence.

Coherence is like a cement in which the observer plunges his trowel: a trowel parallelepiped will allow him to make blocks of this shape and will make a house with these forms. A trowel of another shape, for example cylindrical, will allow him to make cylinders and by assembling them to make a house, other than the previous one.

Of the same coherence - the cement - we elaborate different worlds - houses, the first will guarantee against rain, wind, etc. the second is made for arid and windless regions -.

Coherence is therefore not defined, but it is expressed in its consequences [1].

We have seen in what precedes that a form can be thought of abstractly or placed in a certain neighborhood. In the latter case, when looking at a painting, the expressions foreground and background are often used.

The observer then takes on all its importance. It takes into account the shape and a certain entourage of the form - which, from the usual point of view - would be placed in a subjective way.

Whether the form is seen as an abstraction or the form with its surroundings, this does not interfere in any way the basic assumption of form emerging or submerging into space-time structure (AND).

The form seen in the foreground can be detached from the background or, on the contrary, seen with the background; in this last case we will say that we consider it "pressed" on the bottom.

Stéphane Luspaco [2] points out in his works, the "Gestalt-Theory" thanks to which this concept background was introduced.

This form applied to the background takes on a new character that we call the "AUREOLAIRE" of the form [1], [3], [4].

EUREK'ALL

Let's do the same procedure on the ET, i.e. by structure transport let's map the concept ET on the Global which is existence without landmarks.

It appears the Halo of the ET which is what the Ancients called the *ÆTHER* (*Æ*).

2) Note

The ether of the Moderns is not *Æ* of the Ancients. The Moderns sought the *æther* which they called ether. The Michelson-Morley turn-of-the-century experiment and other experiments demonstrated that ether did not exist.

It was initially, for physicists - therefore for the Moderns - a fluid body, whose existence spread in the Middle Ages, this by what remained of the knowledge of the Ancients. The physicists have taken up the ether to explain the propagation of light. The Frenchman Fresnel, taking up the hypothesis of Huyghens, demonstrated that light is a vibratory phenomenon (or wave) which is propagated by waves; physicists abandoned Newton's hypothesis of a emission of luminous corpuscles.

But if Newton's corpuscles can do without a support, it is not the same for waves. of Fresnel to which a continuous medium is necessary in order to be able to propagate.

But light propagates in a vacuum, which led physicists to assume that all space is filled with a continuous medium: ether.

The ether, not slowing down the movement of the stars, had to be infinitely fluid, but as it transmits luminous transverse vibrations - which Fresnel's contemporaries could not imagine that mechanical - it had to be perfectly elastic - without deformation, like a infinitely rigid steel bar - which is contradictory.

Maxwell demonstrated the electromagnetic nature of light which led to the 19th century the mechanical (contradictory) properties of ether had to be abandoned. All he had left was electrical properties.

Then the role of the ether diminishes to no longer be a mere body of reference linked to absolute coordinates of space. But ether is still troublesome; indeed if there existed a medium such that ether, fixed with respect to absolute axes, the propagation of the light emitted by a body in movement, like the Earth, taking place in this fixed ether in all directions, should not have the same apparent speed on Earth in all directions.

EUREK'ALL

But the speed of light (300,000 km/s) compared to the speed of the Earth in its orbit (10 km/s) does not present any variation as shown by the experiments cited at the beginning: the speed of the light in a vacuum is the same whatever the directions.

Some wanted to explain this failure by the entrainment of the ether but finally the physicists abandoned the hypothesis of its existence.

Einstein, establishing his theory of relativity, showed that there can be no systems of axes favored - absolute axes to which ether would be bound

The speed limit of light is the expression of a shift, an expression in a thought where the landmark leak does not exist. We find by experience, which is placed in the field of usual coherence, that the speed of a mobile cannot increase to infinity; a barrier is put in place, which is measured, and which expresses in usual form a decalar.

3) The halo (continued)

The halo is most often found in poetry in metaphors.

The poet, to convey the sensation to those who delight in his writings, uses a process of the kind: A is to B what C is to D. Most often the sensation is forgotten.

From these 4 written terms (A, B; C, D), there springs a fifth which is still called AUREOLAIRE.

hand, in mathematics, the proportion $g = q$ does ~~not~~ involve any / AC \ On the other

Let's see the 4 terms:

(Form, Content; AND, Overall); this has as halo the $\mathcal{A}E$ and we will state:

The Form is basically what the ET is to the Global, has as aureolar the $\mathcal{A}E$.

When we only have 2 terms, which we saw at the beginning, we go to 4 by the process above.

In conclusion, projecting A onto a background, or stating (A, Background; AND, Global) means the same thing and engenders the same concept: the $\mathcal{A}E$.

There will be other projections of a form A on a form B which will not be the equivalent of a background.

According to Gilbert Simondon [5] conceptualization is to perception what syncrystallization is at crystallization, what we will write:

EUREK'ALL

(Conceptualization, Perception; Syncrystallization, Crystallization) has as halo the Consistency.

Note: Syncrystallization for: crystallizes together in the same homogeneous crystal in any proportion, this forms a homogeneous crystalline mixture.

So we got Coherence as a halo. It can be obtained another way, like equimsey.

Let's see the concept of representation of the obs. - we saw in a previous booklet how obs generalized the observer -.

Let's obs I representation¹ = Consistency

but obs I a representation := domain of coherence.

This makes it possible to associate the concept of domain with that of coherence. Consistency is a unity. It cannot be divided, but this process nevertheless makes it possible to construct the domain of coherence which cannot be approached by a partition of the coherence that we would call domain.

Coherence presents itself either as a halo or as an equimsey.

Maybe there are other possibilities?

Among the Chinese, the seasons were not presented in their natural order of succession, but according to alternations:

- the South complemented the North,
- the West complemented the East.

Then we added a center.

So we had 5 terms: N, S, E, O and the Center.

Consider it this way:

(N, S; E, O) has the Center as its halo.

In the same way the Chinese created correspondences between the 5 elements and 5 colors, 5 notes of music, 5 digits etc. [6]

(Summer, Winter; Autumn, Spring) has the whole year as its halo.

¹ Reminder: A I B means A in equimsey with B.

EUREK'ALL

(Red, Black; White, Blue-Green) has yellow as its halo.

(2, 1; 4, 3) has the number 5 as its halo.

the whole year ^A

the colour

Hence the number 5 > were much more than what we usually put in a year,

a color, a number. These notions are delocalized.

These are the usual notions which are surrounded by a halo, hence the name halo.

Matches go to:

- 5 geniuses of the Orient
- 5 Sky Palace
- 5 Heavenly Signs
- 5 Virtues
- 5 Flavors
- 5 Pets
- 5 Odors etc.

This correspondence between 4 elements which gives a fifth is not done just any comment.

There is a Necessity. Necessity is fundamental as we have pointed out.

One can wonder in the provision (A, B; C, D) the reason for this provision.

The people of that time did not think like us; concepts were natural to them, and arrangements between concepts were also made naturally, like the metaphor in poetry; it is a certain arrangement in 4 terms which conveys a sensation; another arrangement of these same terms is unthinkable.

II. Remarks on the number 71[1], [3], [4]

J. Ravatin in the courses relating to the eifs that he gave in Paris from 1975 to 1993, indicated the following choice civilizations and times of the approximate value given to certain numbers, in particular that of 7C. The history attached to 7C is now considered a curiosity while on this example we can feel the notion of the more or less localized. The importance of the number 7C is such that

EUREK'ALL

we must take up a brief history of it. The Babylonians and the Hebrews admitted that the length of circumference is three times the length of its diameter; the Egyptians identified $7C$

with $y/70$ (which allowed the value 3.1123). Archimedes asserted that $7C$ is between $3+$ and $3+$

$^{\wedge}y$, that is to say between the two decimal numbers 3.140845 and 3.142857. Chinese, Japanese

also found decimal values; in the 15th of our era the Hindu scholar Arya-Bhata had

found 3.1416. In the 16th century the Dutchman Pierre Miétus gave the value $\frac{355}{113}$ which provides five

exact decimals. The Frenchman François Viète around 1593 calculated $7C$ with 10 exact decimal places; in

1610 Ludolph van Ceulen manages to obtain 127 decimal places. In 1873 the Englishman William Shank

gets 707 decimal places. In 1882, Ferdinand Lindemann proved that $7C$ is a number

transcendent. Thus is definitively proven the impossibility of squaring the circle,

that is, side of a square whose area would be equal to that of a given circle.

Marcel Boll, quoting Lancelot Hoghen, adds: "An American state tried to restore $7C$ to its

biblical value (II Chronicles, IV, 2).

No doubt the "reformers" have never seen a pan, nor a tape measure (just

successively measure the perimeter and the diameter of the bottom of the pan, to realize that $7C$

is greater than 3); but these same people mechanically repeat the famous phrase of the

Psalms "They have eyes and will not see", without suspecting in the least that she

applies to them; a fine example of this obscurantism, the deplorable effects of which can be seen everywhere. effects ".

It is quite amazing to see that the Babylonians, the Hebrews had taken the value 3 for $7C$;

the error is hardly conceivable. And yet, that's what they took! Let's see it another way.

The values $3 - \frac{22}{7} - 3.1$ - etc. are too gross to be considered errors. For

our C. de C. they are errors, but in a way voluntary errors. Take 3 for $7C$

it is to consider a circle already delocalized. Thus (3, $7C$; delocalized, localized circle) has an aureolar

which is a circle a little less localized than the circle thought in geometry where the localization is

complete. So they thought the halo, that is to say a depth was felt and had to be

expressed. The circle drawn on the monument was to be placed where this depth is

reflected on the one looking not at the circle but at the monument on which the circle was traced.

EUREK'ALL

This turn of mind led to paths other than the path used now. What's more, even if the circle was drawn according to our geometric formulation, the circle was not thought of in as a circle alone but on a building, in a place, it could be less localized with the surroundings. This is what we have already indicated by saying that two triangles in a plane, in certain positions, may no longer be quite two triangles, one may partially delocalize the other ; looking at both at the same time is not the same as looking at one then the other; in the Cartesian thought we confuse two approaches, because we forget the approach, we do not reinvest it. He it is necessary to reinvest it if we want to be operative: to be operative is almost to ask for permission to begin again a second time an act which, for him, had all its value, because it produced at a given time. This act was not separable from the moment; to be operative is the resume alone and place it at another time, even if we know that it is not exactly the same act; it is here that we understand what humility is: it is the expression of the state of an attitude. "They have eyes and will not see"; Lancelot Hoghen, quoting this extract from the Psalms, forgets that it is like a "backlash" for him. You have to feel the relocation to measure how the Babylonians and the Hebrews, taking 3 for 7T, thought of the circle in a way totally different from what it is in rationalism. To consider a delocalized circle, returns therefore to think much more than the circle.

EUREK'ALL

"We consider the soul

like the thing

the most important

and

the most mysterious of all"

said an Eskimo Iglulik to the explorer Rasmunssen

* This took place at the beginning of the 21st century and went unnoticed. Rasmunssen was dismissed, his work forgotten, and people set out to discover "savages" who were more docile to the theories of the rationalizers.

Jean SERVIER, in his book "Man and the invisible". Edit. Robert Laffont, Paris (1964) adds "No one thought for a moment that this great Danish scholar owed to his Eskimo maternal ancestors to be able to skip the long stages that all seekers go through when they go to the discovery of deep faith. of a people".

EUREK'ALL

Exercise :

A copper wire is wound on a broomstick for example, in the positive direction (also known as trigonometric) - that is to say in the opposite direction to that of the corkscrew-. Five to six turns are enough.

At each end, the wire is pulled straight for about twenty-five centimeters and so that the assembly placed on a table has its 2 strands of wire on the table over their entire length.

Place a pointed pencil on the side opposite the point in the center of a circle drawn on a sheet of white paper (without grid) - the angle at the tip of the pencil being approximately 30° -.

The axis NF, SF coincides with the axis of the solenoid made above.

We will build 2 cylindrical pendulums LH and LY - in square Hebrew -.

- 1) Check that such a pencil placed as above in the center of a circle causes the aura to be emitted on the circle.
- 2) Find the polarities
- 3) Check that on the axis of the circle we detect LYLH

Remark :

This experience is one of those that led J. de la Foÿe to think that at the EFF level, the eifs of the undifferentiated spectrum were made up of the eifs of the differentiated spectrum, i.e. A is composed of Am and Ae.

We must be careful that we are not in the rational domain and that an analogy can

impose itself in dowsing research.

$\overline{\wedge}$
AE

$\overline{\wedge}$
P

About this and other experiences that seem to lead to same conclusion, Jean de la Foÿe was imbued with the model of electromagnetic field where an electromagnetic wave is sub-

* And

V stretched by 2 vectors E (electric) and M (magnetic).

M

If we start from this model and want to impose it, we find it.

This must not be forgotten. It is excesses of this kind that lead waveformists and some geobiologists to erroneous terminologies and conclusions through models and misuse of terms taken out of context like energy, force; they see flaws everywhere; the currents

EUREK'ALL

of underground water does not systematically bring a V'e to the surface, the V'e due to the HV lines depends on the orientation of the line; they forget the states.

In houses they constantly invoke the "memory of the walls". But you have to try to understand what "memory of the walls" means.

Shapes, objects can change state when states are created in their vicinity. It's that change of state which is then captured.

But there is still something else: space has the property of being permeated by shadows:

shadow due to the presence of a shape on a light path. Forms can even keep stable shadows. In the shadows remain present unfolding events. The shadow can even be gone and the event is then existing in space. The shadow left its mark.

Goethe was interested in shadows and he pointed out colored shadows [7].

The shadow gives depth to the space. The shadow is a face from the halo of a form.

4) Check that on the NF-SF axis in the plane of the sheet, LY and LH are detected (the 2 pendulums must answer) but not LYLH.

5) If we draw the circle of radius y, R being the radius of the previous circle, we find the trunk of tree.

6) We put the solenoid in place.

a) Check that at the ends of the 2 wires we detect LH and that in the axis of the solenoid we detects LY for most pen orientations.

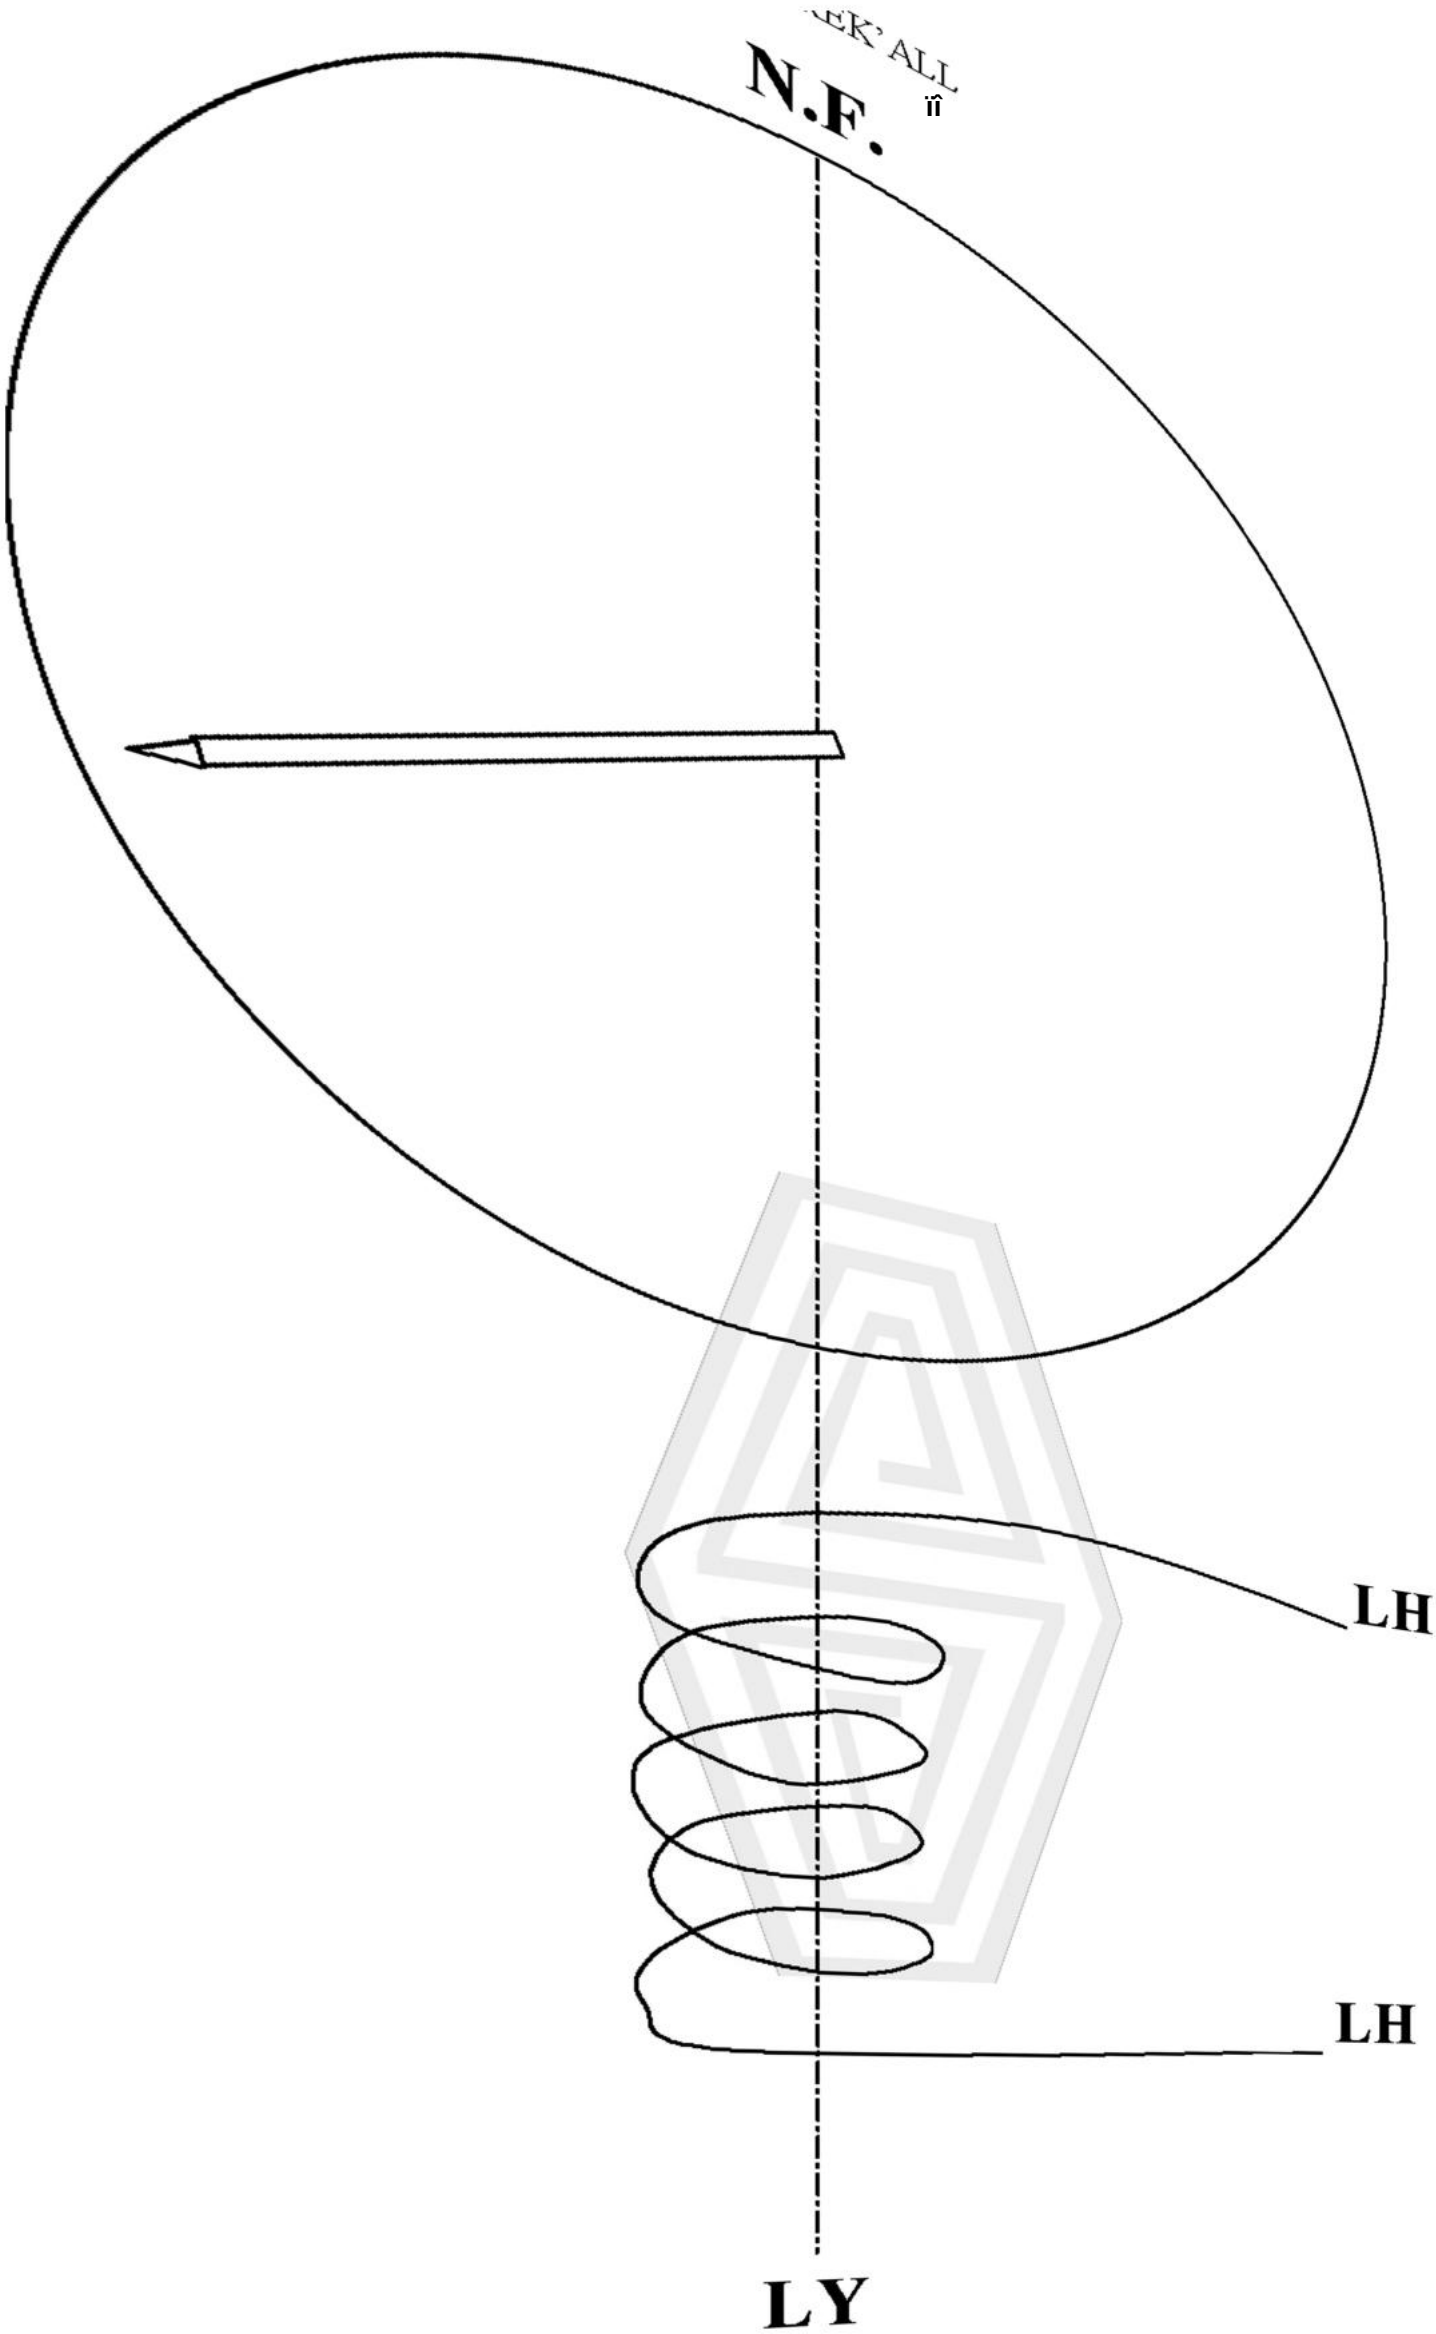

b) At any orientation of the rod, it is verified that the eif previously detected at

V+m has disappeared.

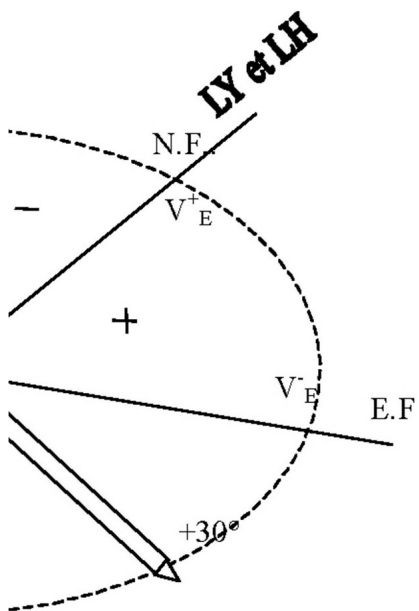

c) If we set the pencil to V4"m or V+e we detect LY on the axis of the solenoid but no LH at the output of the copper wires. The eif V+m or V+e is detected on the axis.

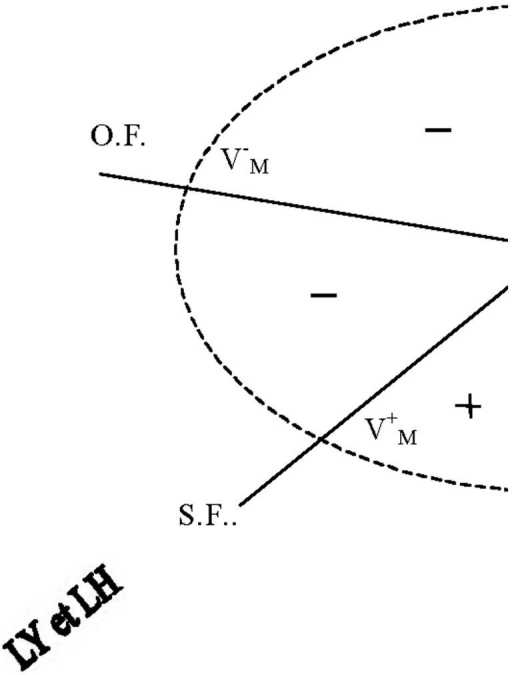

d) If we set the pencil to V'm or V'e we detect LH at the output of the copper wires but not of LY on the axis of the solenoid.

The eif V'm or V'e is detected at the output of the copper wires.

Chapter XI

I. Supplement to Chapter VIII of Fascicle 15

We had drawn Tare of a circle of radius AM which intersects OF in N". We can see that N and N' are very relatives ; in effect :

$$AM = \frac{2}{3} W_2 AC = -j -$$

$$\text{and } ' = \text{Van} 2 ' - ae2 = \frac{59}{100} = 1,5986 = 1,$$

$$EN - EN' = 1,60,0014 = 1,5986 - \text{which is negligible in the domain of eifs.}$$

II. Right triangles with side lengths a, b, c such that $a^2 + b^2 = c^2$

Triangles in general respond to $|K \text{ Sh Ph}\rangle$ but the right triangle with sides a, b, c such that

$$a = 31$$

$$b = 4 > \text{does not respond to } |K \text{ Sh Ph}\rangle.$$

$$c = 5J$$

Jean de la Foÿe had found this result.

But the same is true for right triangles with $n = 2$ and a, b, c integers such that $a^2 + b^2 = c^2$.

A triangle which does not correspond to the state $|K \text{ Sh Ph}\rangle$ is the so-called Cordonnier triangle and whose sides are 1, M/, yVÿ; it is constructed by giving the angles $40^\circ, 60^\circ, 80^\circ$ which are only approximate values but are quite sufficient in this field of eifs.

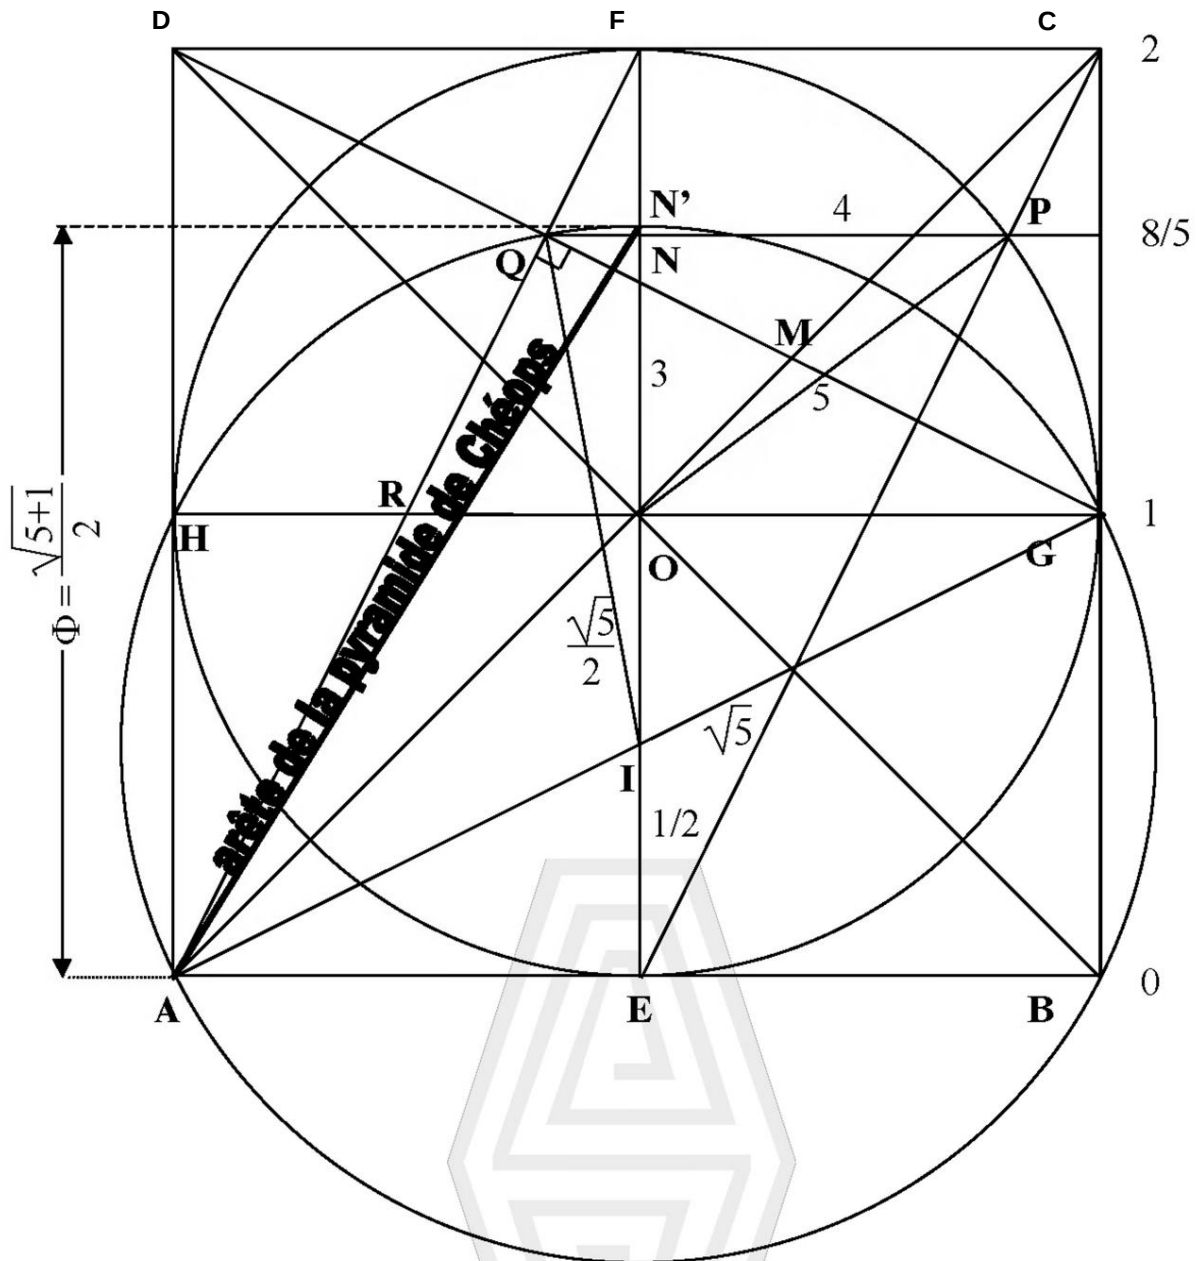

Draw the incircle of square ABCD. Let us draw by Q the parallel to the sides ,AB and CD of the square; it intersects the inscribed circle at P and EF at N.

ON is equal to a height of the triangle DQF.

Triangles GQR and DQF are homothetic so ^

$$\frac{GR}{DF} = \frac{ON}{NF} = \frac{3 ON}{5 \ddot{-} OP}$$

If, in the right triangle ONP one side is equal to 3 and the hypotenuse equal to 5, the other side of the right angle is 4.

Remarques :

- 1) Ces résultats proviennent du fait que nous avons pris l'arête de la pyramide égale aux $\frac{2}{3}$ de la diagonal of the base square. It seems that in this way we enter fully into the tradition.
- 2) By manipulating these plots in this way, we realize that we find fractions which are none other than those of the notes of the natural scale of Zarlin (1517-1590), Italian composer and theoretician, student of Willaert. Most of his works are lost, but he remains, from the point of view

© EÜREECALL

theoretical, an eminent musician. Nowadays, we continue to take into consideration its range based on the perfect chord and formed of fractional intervals [8].

It seems that the scale of Zarlin (or Zarlino) was chosen for musical reasons polyphonic.

By manipulating the lines, we realize that we find fractions which are those of the notes of the Zarlin range. Of course these fractions corresponding to lengths are inverse to those frequencies.

Some notes seem a little "far-fetched", but let's not look here balance, only a series of lines.

We can build Tables in Do, Mi, Fa, Sol, La but the Ré ($\frac{8}{p}$) and the Si ($\frac{8}{y}$) are absent as if they were following the geometry of bastard notes.

The Pythagorean conceptions did not make fundamental differences between arts plastics, music and the description of the cosmos and they are governed by numbers.

One can think that one goes in this direction by finding these relations between Tables and the notes of range.

We can suppose that an architect, like the composer, must operate a selection of proportions that result in harmony. It must be recognized that some achievements architectural are absurd - we check their harmfulness by the eifs and the states that emanate of them.

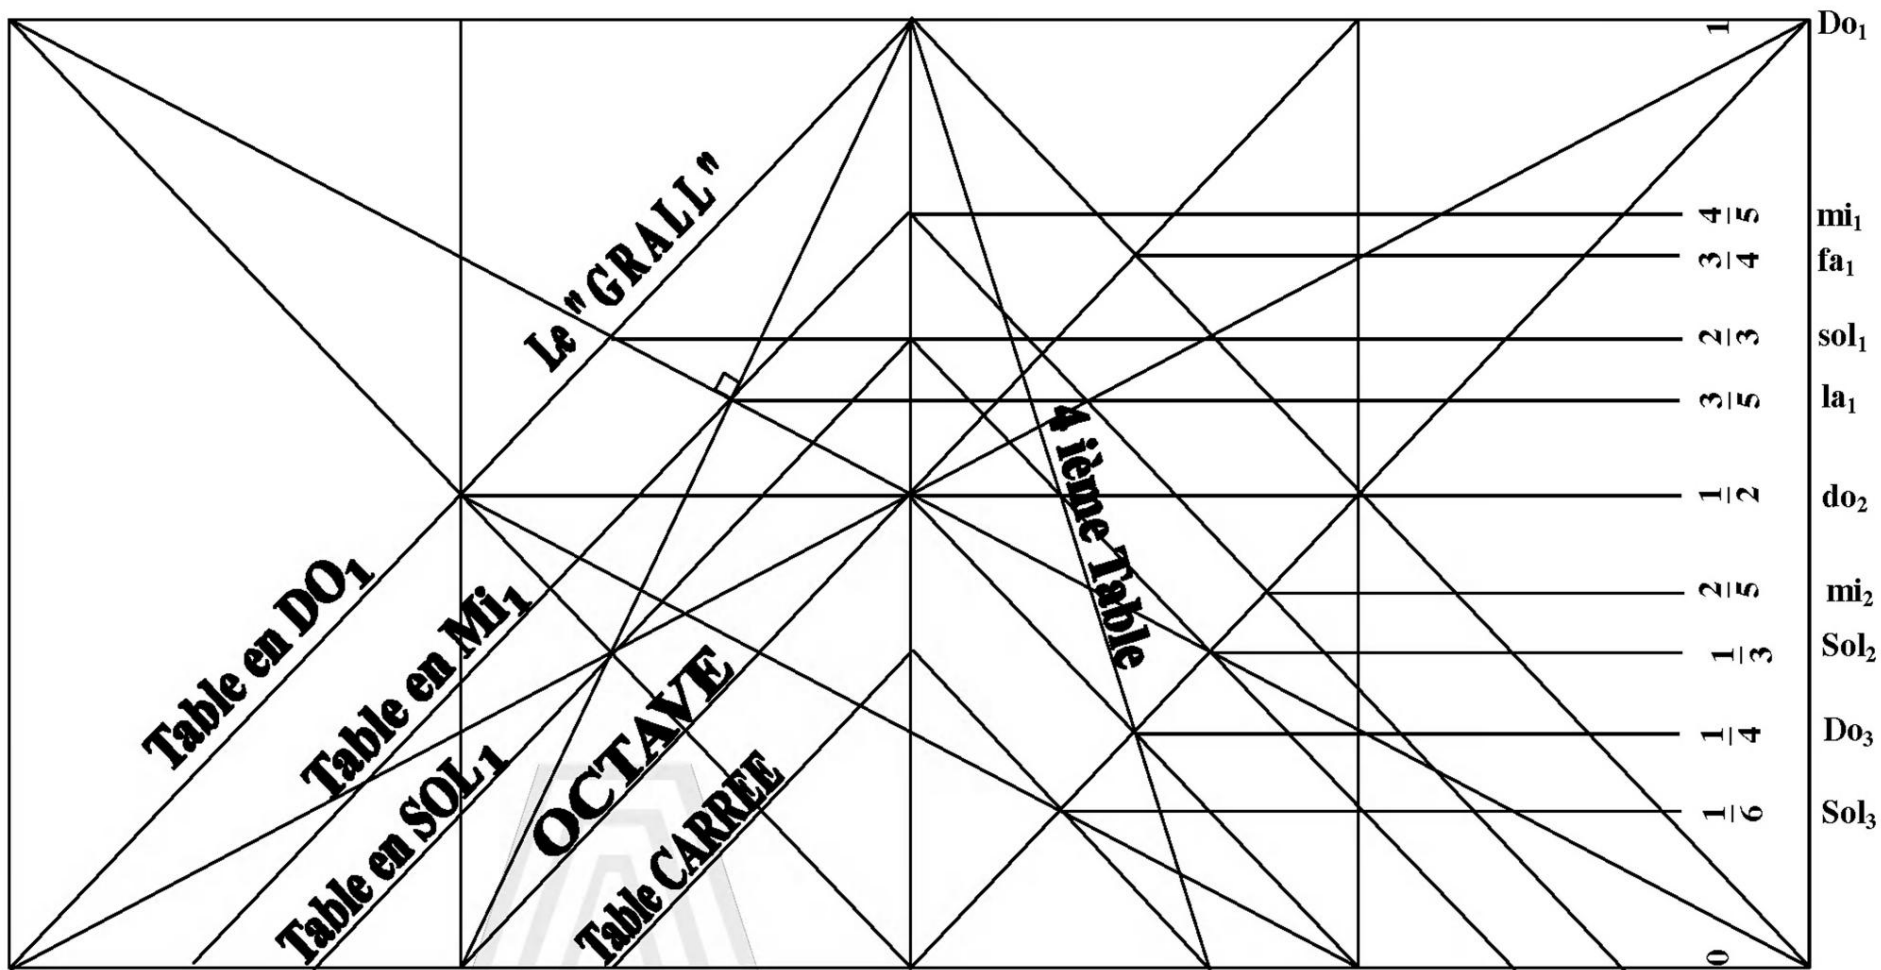

In addition, modern architectural achievements are placed in the middle of constructions old ones and a disharmony presents itself immediately to the sight but also for those who live in the old as well as in the modern.

Note: If we make the 3 Tables and we build the homothetics that will be Mi!,

Ground! for example, they are not in transfer with the respective notes, when these are played by an instrument which gives the pure note or the note with its harmonics, even if the Tables are suitably oriented.

© EÜRECALL

MUSICAL TABLES

On the other hand, if we draw the 41st Table - hexagonal - and the Grail, then the other Tables Mi!, Sol!, D02 are in transfer with the respective notes.

When a musical piece is played in which these notes occur, what is emitted by the polyphony is emitted by this set of Tables - there is not one Table per note, only some notes are represented as E!, G!, D02, S012, etc.

- 3) Regarding the dolmen, eight-tenths of the dolmen tax correspond to three-fifths of the semi-axis of the Grail Table.

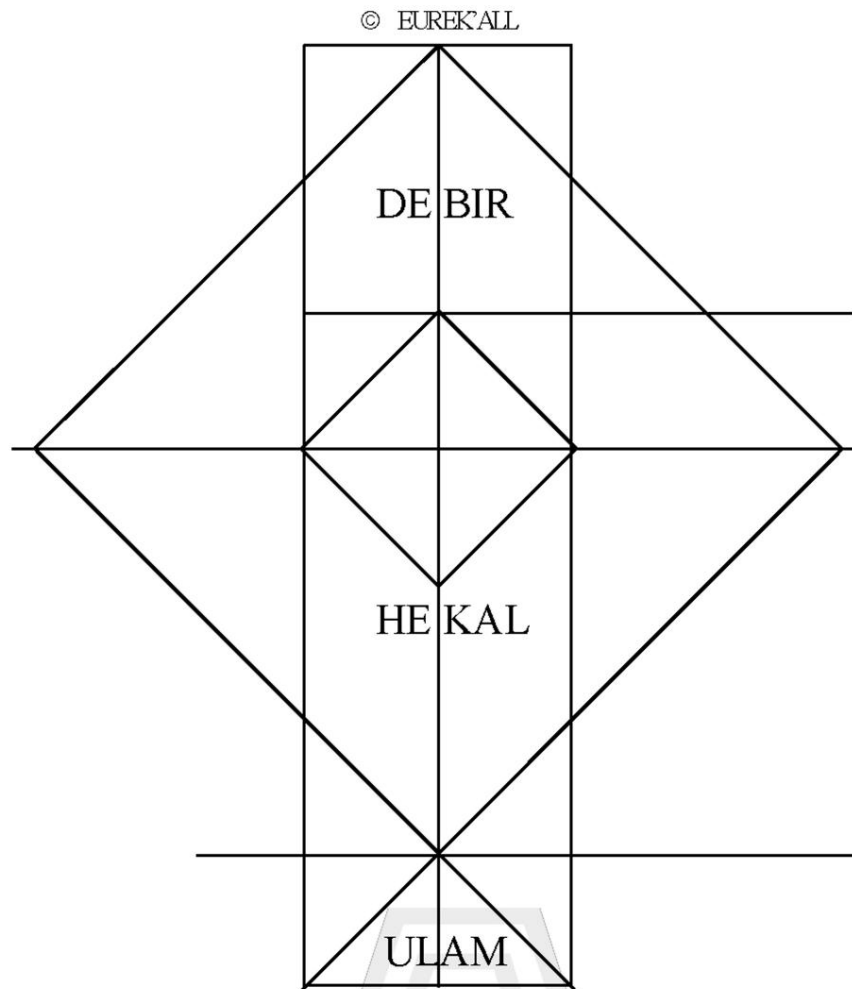

On the other hand, from the historical point of view, it is likely that the designing monks drawn part of their data from the Bible, and also from the direct knowledge that they had the world in which they were; maybe this world wasn't quite like the ours and perhaps allowed itself to be better penetrated. Moreover, the rational coherence field may have slightly erased some structures.

The monks did not have to draw from constructions like the pyramids. But they were also linked to the Great Tradition, the one that has always been talked about a lot and which has been really discovered by Louis Boutard. This researcher, who embraced things before understanding them, from his knowledge of twenty-eight languages came to show - he achieved a lot of devices which confirmed his hypotheses, however very bold - that the Ancients had an immense knowledge and different from current scientific knowledge [1], [3], [4].

He used the Dorian Gnosis - don't let that put some people off, a lot of nonsense has been written as appreciations on Gnosis, but with a genius like L. Boutard everything becomes crystal clear and there is no longer any antagonism between gnosis and Catholicism -.

Remark :

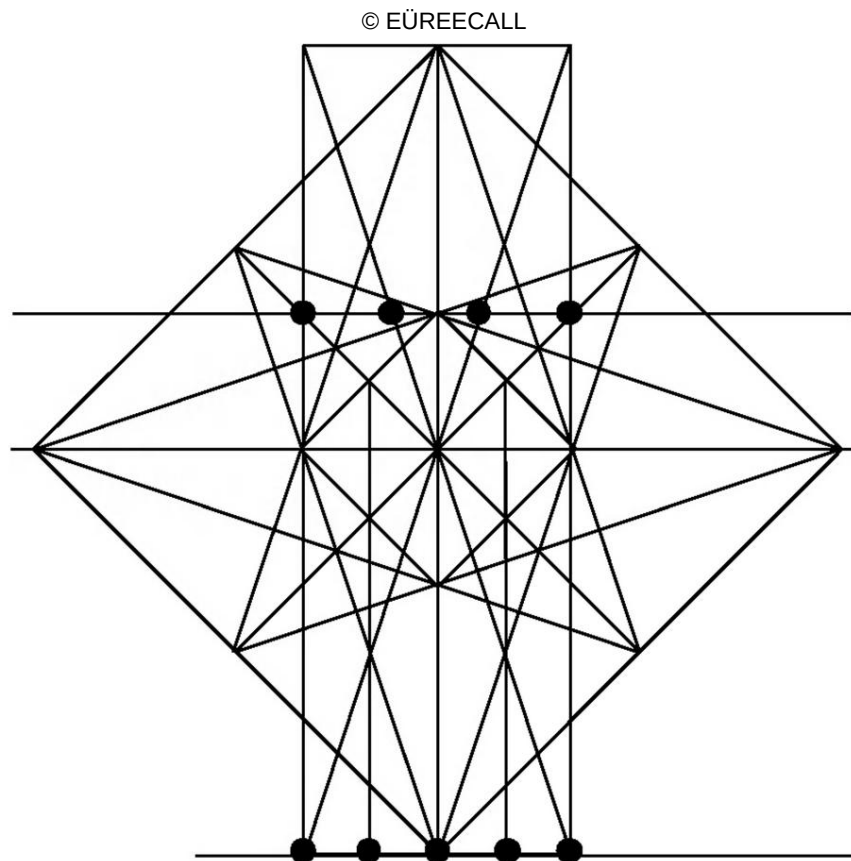

Anyway, it is interesting to research how and to what extent the builders in the past they used the Tables even if it does not make known their origin or that of the "Said".
Let's see the temples of Jerusalem, Solomon and Zerubbabel.

Temple of Solomon

They adopt the Carré and the Carré Long, Argenté. The variants manifested themselves in the vestibule (Ulam), out of the Grail, but attached to it.

The odds are 1 to 1 or 1 to 2.

Tabernacle of Moses

The humans of the time of the menhirs, or let's say the times of the menhirs because on the planet we had to achieve at various times, are not attached to reports. They felt much better the environment and it is not sure that they were looking for a point but rather reasoned by domain or volume in space and were building in that area.

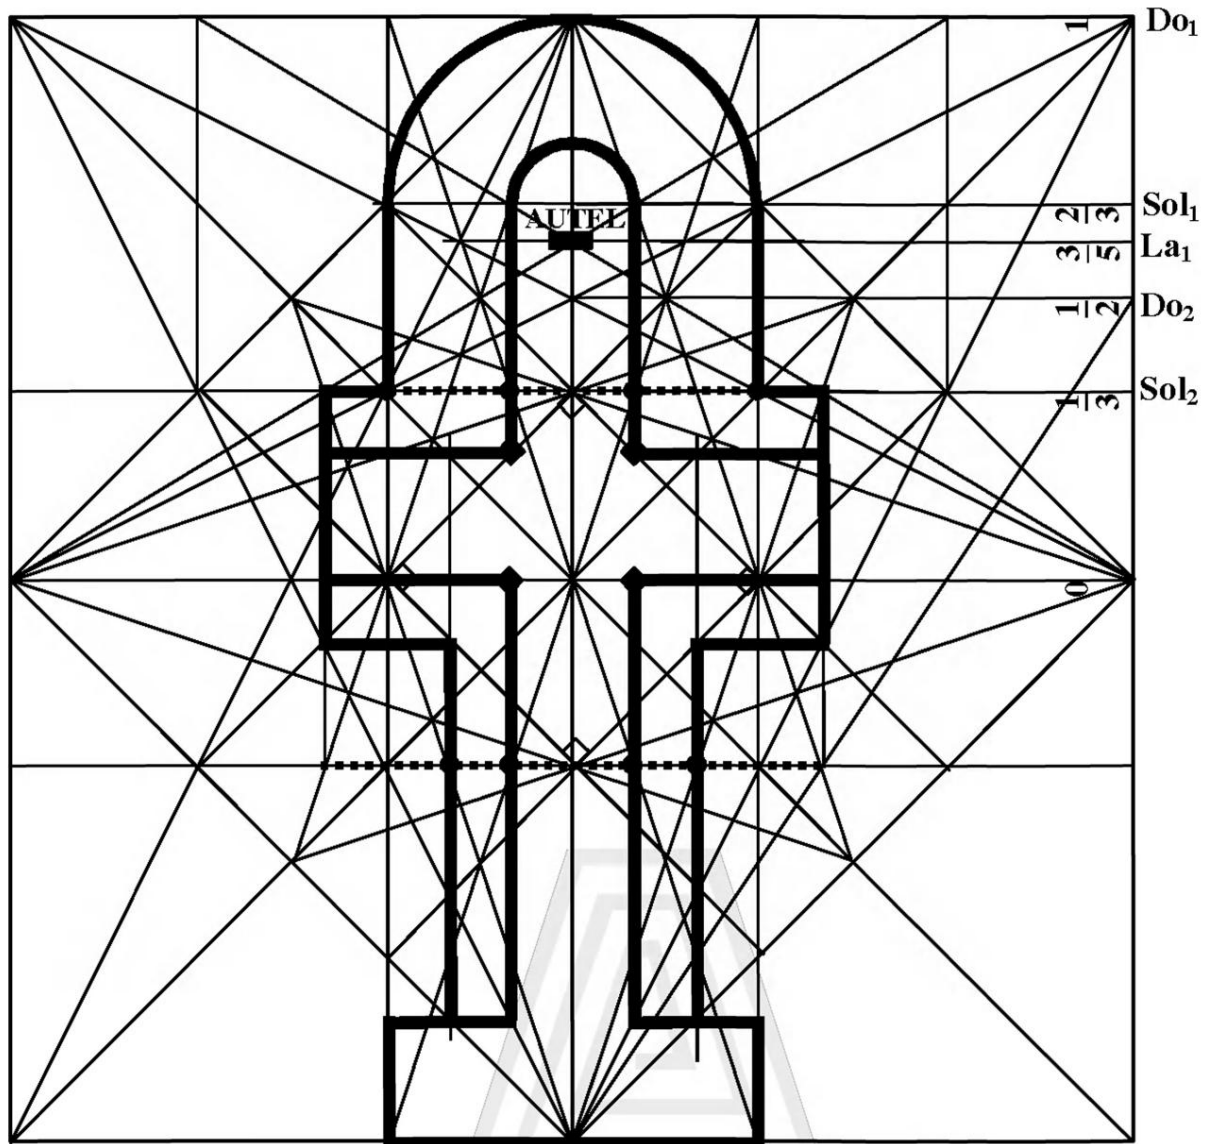

They certainly worked a lot more with what we mentioned above: the "depth of space" or faces of halos of shapes, places.

In these aureolar faces they placed their feelings, their fears, their hopes, their desires; they could thus dialogue with others themselves.

Thus the menhir considered under the modern point of view teaches little even for the waveformists and others.

We can discuss the reason for its location on the bisector of the angle of two lines of esav (see booklet 14). It has been pointed out (fascicle 14) that the menhirs can be used with other shapes to create certain fields (Z and ZD).

© EUREECALL

CHARTRES Schéma idéal du plan au sol

The dolmen taught us the 8/10 of the axis of the Dolmenic Table which correspond to 3/5 of the semi-axis of the Grail Table. It's the only measure of this provenance that you can find in the Tradition based on a religious support going from the time when Moses lived, to the medieval cathedral builders.

With regard to the latter, it is likely that the designer monks drew a part of their data in the Bible and not in the pyramids and other monuments whose precise dimensions must have been rather poorly known. On the other hand, it seems that this period had

© EÜRECALL

also knowledge of geometric data of Pythagoreanism bringing a harmony perhaps steeped in gnosis and Kabbalah.

You should know that gnosis has gone very far in the field of knowledge; Unfortunately You were seen as being in antagonism with Christianity. It may have been but there have always been people who took pleasure in creating antagonisms to use them on others purposes. Moreover, gnosis has been little understood by the moderns, it's a bit like the æther; one can even say that it is now absolutely misunderstood and that only the works of Louis Boutard and perhaps before him Montfaucon gave a presentiment of the intellectual level attained by gnosis. There is had multiple gnosis but in this multiplicity the spirit of the great gnosis was diluted.

Anyway, it is interesting to research how and to what extent the builders in the past they used the Tables even if it does not make known their origin or that of the "Said". It has already been pointed out in previous fascicles of this formation that the Ancients thought differently from us and that it was normal that they easily obtained information from their intuitions according to their intentions and needs. In thought they were much closer to their intuition. These were manifested in the context of their time.

We see that variations between the Temple of Solomon, the Tabernacle of Moses, the Temple of Ezekiel, appear in the vestibule (Ulam), outside the Grail, but are attached to it.

The vestibule of the Temple of Solomon has width 1 and length 2, that of Ezekiel is 3 of wide for 5 long - rectangle called Carré Long Doré (already used in the Arche d'Alliance which particular, is the generator of the Node of Life.

Temple of Ezekiel

You have to dive back into the Bible, which is available to everyone - that's the advantage of this book, on the other hand it can not be read in a common way as certain religious groups do it fluently

Descriptions are still fairly accurate. But let us return to the religious; they made usable constructions which perhaps would have worked less well because there is the question of the moment.

Then they gave flexibility and resulted in the flowering of Romanesque, then Gothic cathedrals.

There are still sketches of these constructions in the neo-classical "Jesuit" style and

in the Gothic "Napoleon III". Appearance and technique delude it, but the skeleton

immaterial Tables is no longer there to create the atmosphere of serenity, balance, well-being that

© EURELALL

remains the lot of the great era with its global knowledge of the links between the monument and the telluric currents, constellations.

Medieval cathedrals rest on a crossing of lines of esav - It may be true for all but we have not verified it Chartres Cathedral seems to have a abnormal orientation; the probable cause must be sought in a deviation of the lines of esav in relation to the cardinal planes.

The diagrams reproduced here clearly illustrate the use of the Tables as far as one can rely on the reduced plans which allowed to build the design and to dominate the real irregularities of the buildings.

The people of the Middle Ages possessed enough of their art to allow themselves fantasies in execution. They knew how to comply with secondary imperatives which did not alter the properties essential elements of the plan, like a plant that never reaches geometric perfection and that is never the serial copy of one of its sisters - moreover identical copies could cause fractures in the rational C. of C.; yet that's what some are starting to put up with cloning -.

Moreover, the companions, workers who worked on the cathedrals were immersed in the intention of creating a building - at that time, their thinking allowed them to do this - and they made "variations on a theme" that were in harmony with the project.

Why was such an ordinance dropped? At least if we judge by the works posterior to radiant gothic, flamboyant gothic, in fact, has already lost the great secret.

Jean de Beauce's steeple in Chartres may be a masterpiece of static balance, but it no longer emits adequate spectrum of eifs - at EFF level -, and it's not just this one! We have already seen the fields of Taofel and there is still a lot to see like VC, FV, the Ifs (4 in number), the Avæcum, its components, the Pavs, the Z and ZD fields, the P-fields, the Arkhams and the Mahkras and that may not be all; you have to remain very open, always listening -.

The Templars, it is said, took away their secrets following the banning of their order by Philippe le Bel, who Philippe le Bel intervened against them at the request of Pope Clement V, and who this pope was put under certain conditions by organizations which for a long time before made a duty to put in place the system that we know.

The Templars probably left geometric rules to operative masons.

Remember that previously the rules were polluted by a mathematical inheritance relating to the number d'Or which we wanted to make the rule of all harmony. This number, as we know, had its great vogue close to Renaissance artists.

In fact, there is strong reason to think that the Templars who were already not the initiators left only processes whose roots once vivified by the Benedictine and Cistercian monks were dead. And as happens with all processes detached from their origins, only traces reduced to professional blows, this for the operatives, and to a symbolism intellectual geometry for the speculative.

But let's not forget that the Templars had understood the concepts of relocation, Global and others - what remains of it has been put in the form of an occult knowledge which has lost all its "substantial marrow" - and so they were less attached to the search for eifs but more to those de C. de T. and their escape, then everything else, down to the ZD fields and the P-fields as well as other existences like the global or the idatheme.

Should we go from decadence to decadence?

The architect, nowadays, in an anarchy that ranges from concrete rabbit hutches - real homes of V e - to the skeleton dressed in tripe from the Center Beaubourg, images of a decomposed society, without ideal, without spiritual reinforcement and without hope, ripe for new barbaric periods, is unfortunately unconscious and serene.

It would be a shame if we could not once again breathe life into a plastic that fits into the rhythms of life. It's fine to go to war in the name of ecology. What good is it if the artificial environments run counter to nature.

To rediscover common sense, you have to think differently - which is developed in the Theory of Fields of Coherence [1] and work on the Forms from this new form of thought that Your present little by little in this course.-.

Ruler and compass will be useful to us but it is necessary to go much further, geometry and algebra are necessary and the mastery of intuition is the most fundamental exercise.

² according to Montaigne's expression.

Chapter VII

The Fundamental Form of Life

I. *The Fundamental Form of Life (FFV)*

The vital field of Jean de la Foÿe does not characterize the living; we saw that we could do it appear on a stone.

We are in a field where characterizations can be transported from one form to another. other.

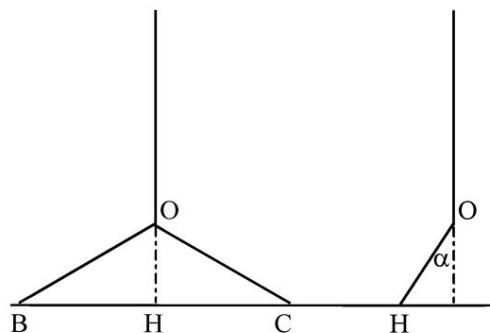

But nevertheless, let's try to characterize before transporting.

A new form is presented which will intervene in all the living: it is about the Form Fundamental of Life.

It is not flat; it is composed of 3 segments OA, OB, OC such that OA is vertical, $OB=OC$ and $\angle BOC=10^\circ$.

Let OH be the height of the isosceles triangle BOC and $\alpha = (\angle OH, OA)$; α is equal either to 33° or to 43° but of these two values it is the first which seems the best, so we will retain 33° .

If we take $OA=OB=l$, we find for OA the value $\frac{1}{v}$ where v is the discovered Radian number by Gérard Cordonnier in 1924 and which we will study in a special chapter reserved, $v = 1.324...$

Remarks :

- This form can be detected on any living being, even on bacteria.

It does not depend on the position of the living being in space, for example a human being can be standing, lying, head down, it is detected in the same way.

It is not in our usual space; it presents itself, for this, as the vital field. Can we say why it is delocalized? Yes ! We're here represents as being in space, but it is not there.

II. Form associated with FFV

FFV has a very interesting property that has multiple applications. At the vertical of O, at the level of BC, a completely delocalized form is detected.

It is called rhythm form associated with FFV. We find a fixed form which realizes this rhythm. In the expression of a rhythm, there is no origin so the form could be constructed from a circle.

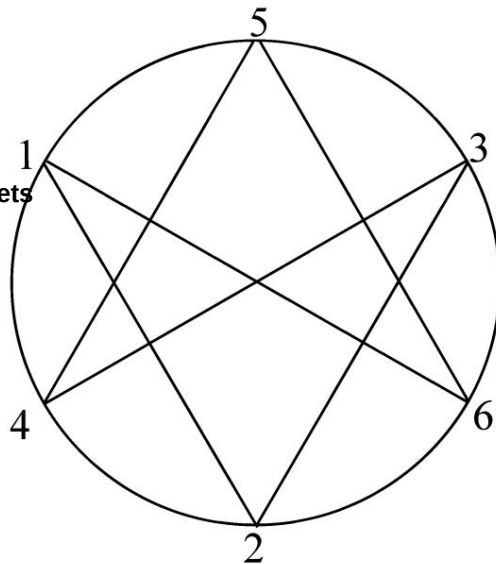

It is a flat, closed curve. The circle serving as the base is retained.

The rhythm can be expressed as $\{(1, 2, 3), (4, 5, 6)\}$ i.e. 2 times a group of 3 and then repeat the same. The circle will thus have 6 marked points.

Let's draw a circle divided into 6 parts equal, of which 6 points are listed from 1 to 6 as in the figure:

The segments will be designated by the doublets 2 digits, the first designating the origin, the second the extremity.

$\{1, 2, 3, 4, 5, 6\}$ is a hexagon irregular star.

The figure should be understood as follows:

$\{2, 1\}$ turns into $\{2, 3\}$ which we will write $\{2, 1\} \rightarrow \{2, 3\}$.
Then $\{3, 2\}$ becomes $\{3, 4\}$, $\{3, 2\} \rightarrow \{3, 4\}$ then $\{4, 3\} \rightarrow \{4, 5\}$
 $\{5, 4\} \rightarrow \{5, 6\}$ $\{6, 5\} \rightarrow \{6, 1\}$ $\{1, 6\} \rightarrow \{1, 2\}$

and it goes back to the beginning.

The hexagon with the circle emit what we call the first field of Taofel which is an eif which belongs to the class of eifs known as Taofel fields, but this one will not be studied in this course.

Exercise :

We can make an assembly with transistor and LEDs that light up according to the rhythm

$\{2,1\} \rightarrow \{2,3\}$	That is, $\{2, 1\}$ lights up first and then after $\{2, 3\}$. Of
$\{3,2\} \rightarrow \{3,4\}$	$\{2, 3\}$ or $\{3, 2\}$ we then move on to $\{3, 4\}$ etc... And so on.
$\{4,3\} \rightarrow \{4, 5\}$	The frequency should be such that the eye no longer sees the changes.
$\{5, 4\} \rightarrow \{5, 6\}$	The frequency is determined with a pendulum. This varies according to
$\{6,5\} \rightarrow \{6, 1\}$	fixtures. Eifs come out and leave about twenty meters away
$\{1,6\} \rightarrow \{1,2\}$	but can wear further if fitting size is more
etc...	big. We obtain eifs which are very good for the health of
	living beings, these being placed at about 1.50 m to 2 meters from
	the device.

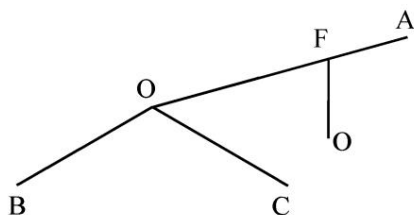

Eifs are not in the EFF domain; we find the fields of Taofel and two others

eifs which are Creative Verb and Famous Green (this one has nothing to do with the V+ or the V, Vÿe, Vÿm, V+E, V+ M).

Remark :

Let us consider these beings who were sometimes observed, often for a very short time, by travelers on land or sea; this is the Loch Ness monster and other monsters lakes, sea serpents, beings such as the Yeti of the Himalayas, the Sasquatch of the western Canada, specifically in the mountainous region of Colombia British, further north, just across the border from the United States, they don't have absolutely not the FFV

Another form is associated with them. In perspective it looks like this: OA is horizontal.

$(OB, OC) = 120^\circ$. The angle of the BOC plane with OA extended is another 33° . Moreover there is FG which is perpendicular to OA and vertical and located in the plane of symmetry of OB with respect to OC.

We have $OB=OC$ but OA is no longer equal to $\|1$. Its length may vary depending on the location.

With UFOs, sometimes such forms are associated. It is associated with a form-rhythm which is not detectable in the extension of OA and is totally different from that found for living systems.

In these beings - aping of the living - we do not detect a vital field, where at least there is not like the one we described in the previous chapter.

Exercise: we will practice detecting FFV associated with humans, animals:

cat, dog, plants.

Note: Sometimes humans do not have FFV. It's quite rare. Yes

However this happens, one has to see the health condition of the person in detail. There are anomalies.

“And the moment he knew it, he ceased to know it”

Jack London1 II

I This thought is the last of the work of J. London, “Martin Eden”; it expresses the death of Martin Eden who sinks into the ocean.

Jack London: born in San Francisco on January 12, 1876. His story is a novel worthy of those he wrote; he was, one might say, his own model.

He was the natural son of a traveling astrologer of Irish descent. His mother, shortly after his birth, married John London, who gave him his name.

Miserable childhood, on a ranch where he watched the bees, then in Oakland, where his parents ran a humble drugstore.

He had many jobs, was sometimes arrested for vagrancy, but had a taste for books early on.

At fifteen he became a sailor and sailed the seas.

At nineteen, he entered the Oakland School, then the University of California.

In 1896 he left for the Klondyke.

Called back to Oakland by the death of his stepfather, he published short stories in various magazines and began to live by his pen; but he quickly squandered the often considerable sums he earned.

In 1903, his admirable “Appeal of the Forest” was released.

From the Hawaiian Islands where he went with his second wife, he brought back “Martin Eden”.

He committed suicide on his luxurious ranch in California on November 22, 1916.

It is also interesting to talk about him being linked to Jules Verne by a mysterious group of 7 people including Jules Verne, Jack London, Amundsen, Edison... and an even more mysterious Dad who seems to have wanted to make known to humanity a path of science and wisdom. But it seems she refused. We talk about it in Vladimir Roznilk's book “The Emergence of Enel or the Immurgence of Landmarks, Introduction to the Study of Forms and Coherence Fields” (Volume III page 705).

About Jules Verne we learn that he was attached to a form called Pentacle of Jules Verne or Medal of Jules Verne.

This form has multiple properties.

Chapter VIII

States and levels of Equivalence

I. Introduction

To implement the concepts of state and equivalence level, we need letters from sacred "alphabets" such as Hebrew. We will only stick to this one. But one could consider Sanskrit, characters from the Easter Island tablets or the so-called "enochian" characters of John Dee, Queen Elizabeth I's astrologer. He had him been given by the use of a certain mantic, characters which he used effectively in his experiments. He had achieved great operability.

II. Hebrew letters

Thereafter we will not use the letter name for these forms but the Hebrew name: *aleph* and in the plural *alephoth* because they contain much more information by their form than the letters of our modern languages.

There is an exception, it is the Basque which uses the Latin letters but the words emit all what we can detect with Hebrew, on the other hand the letters do not emit very interesting.

Basque is one of the most difficult languages to learn - 12 declensions per word - from world but of an incredible richness. Basque folklore is also very interesting, you have to do this, immerse yourself in the works of Father José Miguel de Barandiaran, unfortunately only one work has been translated into French² ; the rest is written in Basque. A only translation of his immense work has been made in Spanish³.

The Hebrew must be written in so-called "square" - biblical - Hebrew, otherwise nothing can be detected.

² José Miguel de Barandiaran, Basque Mythology, Edit. Annals of the Pyrenees, ESPER Association, Toulouse, (1989)

³ Refer to the book by Jacques Ravatin and also the one soon to be published by Jacques Ravatin and Anne Marie Branca "Theory of Forms and Fields of Coherence" (to be published).

The autioth are, for each, developable into several autioth. It is very important because this enriches what is linked to an aut and a word when we do this development for each aut du mot.

Moreover, each aut corresponds to a number. Note immediately that there is no connection between the number associated with the aut and the number. For example, to Aleph it corresponds 1, to Beith it corresponds to 2 and to Tâv it corresponds to 400.

On the attached table are 2 correspondences:

- The one indicated under each aut which is the correspondence of kabbalists and rabbis.

I 2 9
10, 20, ..., 90
100, ... 400, 500, ... 900

There are 22 authioth, but when some are at the end of a word - in final - for 5 of them they correspond to the numbers 500, 600, 700, 800, 900.

Note that there is also a correspondence between the letters of the Greek alphabet and numbers. In this alphabet letters were withdrawn by the high priests as by example the koppa (which is not to be confused with the kappa). Recent work carried out by researchers from the EUREK'ALL Company, the DECALUM association and the group ARK'ALL showed that the koppa had strange properties and allowed to go very far. For this we must work on what we have discovered and called the P-Fields - for almost-field -

By test, there is no link between an aut and its associated number. So you don't have to understand the number like 10, 20, 200, etc... but like the succession of digits 1 and 0; 2 and 0; 2, 0 and 0 but that is not enough: you have to build a sequence for each triplet of numbers.

- On the autioth table at the top of each letter, on the right is the order in which they are distributed. It is this correspondence which was preserved by G. Bardet who criticized violently the rabbinic numbering.

From the correspondence of G. Bardet, Jean de la Foÿe drew what he called "the canons" which are cylindrical sticks on which are carried grooves corresponding to the autioth but these autioth are represented by Bardet's numbering.

One could also, in Bardet numbering, use sequences starting either from 2 numbers for example and placing a zero to the left or right of the number(s).

Bardet established a writing of the autioth which is practical when one has as in the case of Computer use has difficulty using Hebrew characters directly.

Remarks :

- Thus the autioth go from hA to Th.
- In Hebrew language should be felt, not as grammatical understanding, but given in bulk.
- The first 9 autioth are said to be archetypal.
- For Carlo Suarès⁴ :
 - the autioth linked to the units intervene in the domain of the archetypes.
 - the autioth linked to the tens intervene in the domain of the incarnated.
 - the autioth linked to the hundreds intervene in the cosmic domain.

We will not make such a distinction and will not use this breakdown.

- We say Hebrew or Esdraic writing.
- Hebrew is written from right to left.

When we take Bardet's handwriting, we will do so from left to right.

But it must be said that the writings of Bardet autioth or words emit nothing.

When you want to detect eifs, test states, make clocks with aut or word, you have to take square Hebrew.

The ancient languages, often sacred, correspond to a thought that is no longer ours. But the forms of the signs, of the autioth in this case, carry with them the reason for their creation, the reason for their form, the meanings information. You have to wait and not to impose once again the usual thought.

- 150 years ago, Champollion published his famous memoir on the "Hieroglyphs phonetics".

He said: "Egyptian hieroglyphs neglect vowels, they represent only the consonants".

It was a successful but mistaken working hypothesis. It will cause this double false assertion: "The Hebrew letters and the Arabic letters are only consonants".

Sir Alan Gardiner, in his monumental "Egyptian Grammar" observes that certain signs Egyptians do not only represent consonants.

⁴ Carlo Suarez: "The Kabbalah of Kabbalabs"

There is a full writing, that is to say where the vowels are written. In the 261st dynasty, vowels were written and this in certain regions.

Similarly Régis Blachère in his "Elements of Classical Arabic" specifies that the signs Waw and Ya have consonantal value when accompanied by another vowel, but are long vowels when they are not articulated with the following vowel.

In reality, all pronunciation requires vowels; in a language like Czech, we puts vowels even if they are not written.

One may wonder whether intelligible sounds in languages are necessarily heard if they do not contain vowels. And there we feel the concept of vowel emerge. So we don't cannot say: there are vowels or not, but it must be said, there is emergence. This is the way for talk about vowels.

- Note that if Champollion deciphered the hieroglyphs, he gave only one interpretation. Another was found by a French researcher Louis Boutard. And in this other interpretation there is this game of the mind that you find in particular in Kabbalah and which was appropriate among the Ancients.

Champollion, through usual, analytical thought, rethought ancient languages that were not not very analytical despite the discovery of grammars for them.

It may be secondary to a system of expression and understanding.

- Let's see the hA: it is the existence that corresponds to the existence without landmarks and existence of concepts - Concepts, for some, are before benchmarks. They can announce them.
The hA is linked for example to the concepts of global, local, field of coherence, radius of coherence, coherence swarm, island of incoherence, etc...

We say that the hA is the 1; it is the 1 next to the 1. He agrees to be in tension⁵ with the 1 for imbibe 1.

The B6 : for the same reason as the hA, it is the 2: the 2 without which nothing would be but it is also all the "mansions" - philosopher's mansions in the sense of Fulcanelli -, that is to say the remains just, the real one, the one you need.

This word remains corresponds to a delocalized concept. It's a bit like the concept of home but it is still different.

⁵ See book by J. Ravatin and Anne-Marie Branca, Theory of Forms and Fields of Coherence (to be published)

⁶ See correspondence table between Autoth and Latin script

For Carlo Suarès, the B is the archetype of all containers, "homes".

This is the exact concept.

In B, there is hA.

But the hA contains all the autioth.

- The autioth are for each developable. This is important because thanks to these development of each aut of a word, one can move on to other words or even elaborate new words. These last, one can verify it by mance, in certain cases not will not be rejected.

We will give this development for each aut in a vertical arrangement of autioth.

hA BGDHWZ		CHO THO
LYYL	hA WYYY	
Ph th M TRIAL	N	Test
I		

YKLMNS		ch A Ph Ts
At Ph MMWY HA D		
D	D	NKN
		AND

Q R Sh Th
at YYW
Ph Sh FEMALE

We therefore write a word and under each aut its development. Reading horizontally he can to form other words or even sequences of autioth which, as we have just pointed out, do not have apparently no sense.

III. Hebrew words

When working on forms and using Hebrew, you have to walk around the word, around the autioth set of the word. We can only stick to one meaning of the word; in Hebrew if we focus on one meaning, where the other sounds are less present. That is what is called the "Nebular" of the word⁷.

Let's see for example BR hK Sh Y Th⁸, the first word of the Torah⁹.

⁷ Name of the in-depth developments on this Nebular term, we will refer to the work of Jacques Ravatin and Anne-Marie Branca already quoted.

⁸ Berechit is the pronunciation

Translation from Hebrew into Greek, from Greek into Latin and from Latin into French, or from Greek into French leads to "In the beginning", which in current thinking does not correspond to anything compared to the original meanings - because the meanings are multiple, not in the sense of several but in the sense of cloud containing potential information that can change depending on the shape of the cloud, the pressures inside or outside the cloud, etc... The word is there to remind that it is ready for anything as long as we know how to use it -.

Example : BRhA Sh.Y Th

Meanings: Invent look with intention,

lie throw,

suppose to hide, to move, to travel, to move, to stay

lurking, hiding

Thus with Berechit we feel that it is already a question in what is to follow - if we consider the sequel which constitutes the verse because it is said that the continuation is in this word -, that there will be invention, creation but it's like hidden, we suppose, there is the intention, we have to look, move, steer, be careful, observe. We thus arrive at the diagram presented in Volume IV (Page 1101) of "The emergence of Enel... "9 10 where 3 signs *h*, *_s_* are used which mean:

$\wedge\dot{y}$ is sufficiently similar

***h* suppose**

to be (in the sense of existing)

hC
a and is read when we write Je $\begin{matrix} A \\ A \end{matrix}$ where A is a presence, a thing, finally what is

observed, what we are talking about. We state:

A is sufficiently similar to what so that I guess what Supposed to be
What A is A looks like enough

9 The Pentateuch in Greek -the first book of the Bible which includes
5- 10 Vladimir ROSGNILK, The Emergence of Enel or the Immergence of Landmarks. Introduction to the Study of Forms and Fields of Coherence, Editions ARK'ALL Volumes I and II (1985), Volume III (1988), Volume IV (1990), Paris.
Jacques RAVATIN, Coherence Field Theory, Edit. C. Lacours, Nimes (1992).
Jacques RAVATIN and Anne Marie BRANCA, Theory of Forms and Fields of Coherence (to be published)

In Berechit there is that. Berechit expresses the value of human formulation¹¹ and

man's attitude to this formulation. Also in the scheme I

1A A

A A the

is suggested that to create one needs the intention of the intention. This is the two^{11 12} - the 1 not being accessible to man but which is found in the accessible form which is the divine ternary of Enel, the Prince Skariatine.

But we can also work on Berechit in the following way:

B-R hA-Sh Y-Th
WHERE B R-hA-Sh Y-Th
Where B R-Y-Th hA-Sh etc.
etc...

Then we use the development of each aut:

B R hA Sh Y Th
THEY
Th Sh Ph N D

And work with the 2nd and 3rd lines as we did for the 1st

Let's see an expression from the beginning of Genesis:

Earth is Tohu-Bohu.

Tohu-Bohu has a very particular meaning taken in French, i.e. confusion, disorder, often noisy: "it's a real hustle and bustle".

Th HWWBHW these 2 words mean the same thing

i.e.: Chaos, emptiness, void nothingness, desert, loneliness, confusion, disorder, condition chaotic, futile.

The same meaning entails a vision of 2 as expressed by the Templars in their seal: 2 riders on the same horse¹³.

Complementing this writing of Tohu-bohu is the expression: fiui means
chaos, shapeless mass, nothingness, solid, desert, void, vanity, vain thing, deserted place, dreadful place,
a nothing, obstruction, digression, confusion, disorder.

¹¹ We will say for observer man or more precisely Obs what is more general than the observer - see the works of V. Rosgnilk, AM Branca and J. Ravatin.

¹² See the work of Jacques RAVATIN and Anne-Marie BRANCA already quoted.

¹³ This is called a T system. See "Theory of Forms and Coherence Fields" by J. Ravatin and AM BRANCA (forthcoming).

Thus it is seen that sacred languages, such as Hebrew, Sanskrit, and others that have disappeared, like no doubt the few that have been found on the 28 still existing tablets of Easter Island, were quite different from what our modern languages have become, at least what we think of them.

One can then suppose - but this is only a supposition that moreover some researchers have considered - that at the beginning of humanity there was only one language. If she still existed is it necessary to have a representation that leads to the establishment of an origin of humanity; in the works of Vladimir Rosnilk, Jacques Ravatin and Anne-Marie Branca, it there may be different origins to humanity, this depends on the Ray of Coherence chosen and enters the so-called Coherence Field Theory Model - so we can think that we would be faced with a language that would have been evocations in the process of evolution.

The words are hardly expressed, they are similar, we pass from one to the other by a drift¹⁴, as one would pass from a blue to a yellow of the visible electromagnetic spectrum in using all intermediate wavelengths. It's a poem where the evocation is launched towards the one who waits and when he receives it she transforms him into a radiant source.

If with Th HW Sh YW we want to use numbers

we start from 400 5 6 300 10 6

That Ton writes thus:

4 0 0

0 0 5 And we read the sequences constructed as we established previously.

0 0 6 We will not go any further along this path which is very rich.

0 0 3 extraordinary but which quickly takes us out of the scope of this course.

0 1 0

Note the expression: The Earth^{^ ^ ^} ; the name Moses^{^ ^} ; A Sh H Woman

Let's go back to the expanded hA:

¹ ha We can have fun doing the total: either 111 and summing the 3
30 liters number 1 which gives 3. It should not be deduced that 3 is the ternary
gQ pk divine and that the hA contains this ternary. This then is the esotericism of
low class, moreover it is the one found almost everywhere.

You have to work like this:

¹⁴ Deviates from the meaning of the works of J. Ravatin and Anne-Parie Branca.

1→00 1

30-----> 0 3 0 j̄and build the appropriate sequences then add them.
80-----> 0 8 0 J

Advice: For any work involving Hebrew, you must have the dictionaries available.

of the kind :

Abraham ELMALEH, New Complete Hebrew-French Dictionary, Edit. Yavneh, Tmes
I, II, III & IV, Tel-Aviv (1974).

And French Hebrew

Menahem BANITT, French-Hebrew Dictionary, Volumes 1, 2, 3,4, Edit. Masada (Israel)

Example :

Consider the word Sun: Sh Ms h in which we develop each aut.

Sh M Sh

YYY |

NMN | Arrived at NMN we continue the development
EASY

NMN nly And this happens every two lines:

MN ----- > manne

NM ----- > dozing

This causes the sun to bring manna in a dormant form. Looks like in our time,
the potential state.

And so NMN could be, if we use the language of forms, the equivalent of the form
associated with emptiness.

N-----> fish but it is the expression of the feeling that one has when one sees a fish
to undulate, to move in the liquid medium.

But it is still: swarming, degenerating.

This means that NMN presents itself as a biological medium between two dynamisms.

And it is enough to unbalance one of the two to pass from a potential state to a kinetic state, one
would say more correctly to pass from dynamism to localization.

⁵⁰ ^ 3001 serPent but also augury, spell, oracle, presentiment, divination, omen,

enchantment, prognosis, auspice, magic, superstition.

And we will also use a lot K Sh Ph (the point above for the schin) which means to be

^{20 300 800}

bewitched, be enchanted.

Note: do not forget the Ph which is in the final therefore not 80 but 800.

And K Sh Ph YM for magic, sorcery, divination, enchantment, spell, arts

20 300 80 10 600

chimerical, evocation, magic, incantation.

There is also hAWB.

K Sh W Ph - M Th Y M

D R Y Sh H

hAL HM Th YM

We will have to use pendulums carrying K Sh Ph¹⁵.

We will then think magic, but in a sense where it is a state that is not made to be.

human or for which the person approaching the form or forms is not ready for this exercise. May besides that there exist states which characterize forms for which the human being does not cannot undertake a study.

There are such forms - which are called "intestable" - which effectively give nothing or almost about their properties but despite this do not respond to K ShPh where to any other such state.

You should know that when we have an answer to KShPh it will be the sense of magic but impregnated by all the senses presented above.

They constitute what is called the "Nebular" of the word.

In our modern languages words have nebulae but they do not permeate the word.

But it is not only the form of the autioth which intervenes to use the nebula of the word, it also needs the mindset. We naturally have this state of mind - there are few individuals who are like this - or you can take it little by little by working on the works of Anne-Marie Branca and Jacques Ravatin as well as that of Vladimir ROSGNILK already mentioned. The elaborate thought in these books is called Arkalian thought, from the name of the group ARK'ALL.

Appropriate pendulums:

It is necessary to make pendulums for the words K Sh Ph (magic),

H hA R Ts (la Terre),

¹⁵ The Sh must be pointed "in the middle", without this, there is no answer for the search for this state because we will see later, it is a state.

¹⁶ We will see other states of this kind when we approach the study of the states

LN Ph Sh cH YH (the Breath of Life),

RW cH (the Spirit),

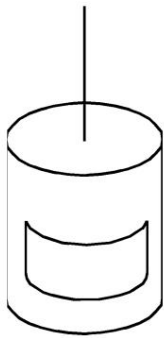

YHWH - one of the names of God, we find others in the Thôrâh¹⁷ ,

hAWR ((the) Light),

Y Ts hA WMYM (He will spring water),

RWcH,

Sh T N.

We make in a hard plastic material as we did for the pendulums of the 4 components of the vital field and of the schin, a cylinder on which we paste the word in square Hebrew.

Supplements:

Sh TN Schatam, that is to say satan, evil inclination messenger of death.

300 9 700

H hA R Ts pronunciation: haretz

Meaning: Earth

LN Ph Sh cH YH prononciation : La Nephesh Raïah

Meaning: breath of life

R W cH pronunciation: rouach

Meaning: spirit, but also: air, wind, strong breeze, breath, breath, respiration, aspiration, soul, life, ghost, passion

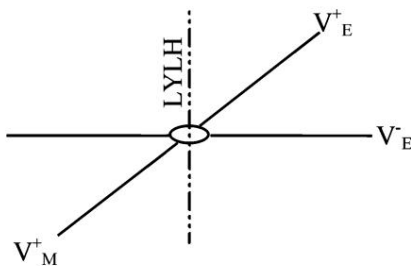

Then sides, flank, heart, vanity, nothing, frivolity, courage, desire, will, anger, anger, conscience, werewolf, demon, evil mind, recollection, memory, idea, thought, intelligence, consciousness.

Exercises: We start with a sheet of white paper, we draw any triangle on this leaf.

- 1) Check that in general the pendulum K Sh Ph reacts above the triangle.
- 2) Jean de la Foÿe had noticed that in the case of right-angled triangles of sides 3, 4, 5 the K Sh Ph pendulum was not responding.
- 3) Check that more generally the pendulum K Sh Ph does not respond on any triangle rectangle of sides n, p, q and where $n^2 = p^2 + q^2$ and where n, p, q are integers - This recalls the Fermat's theorem.
- 4) Check that in the same way the pendulum K Sh Ph does not respond on a triangle of angles $40^\circ, 60^\circ, 80^\circ$ - this is linked to the Radiant number of Gérard Cordonnier-.

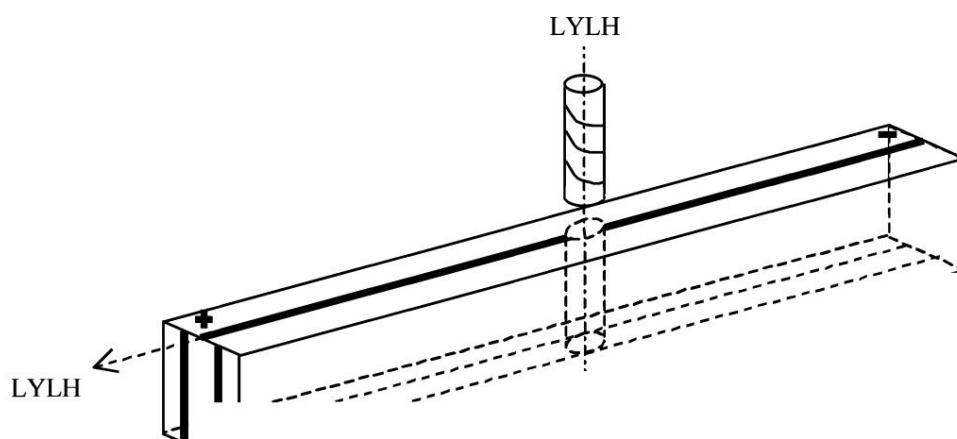

Exercise :

- 1) Check that the tree trunk, since it has its 2 perpendicular axes in pure E and M pure, we detect perpendicular LYL H.

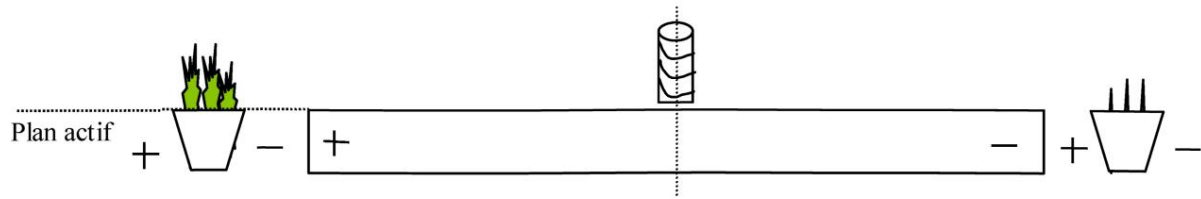

- 2) We start with a parallelepipedal piece of wood as shown below.

We impose a polarization with the grooves and a hole in the center and an antenna with a solenoid +.

a) Whatever the direction, we detect at the places indicated LY L H.

b) Same assembly with flower pots.

1) Check the polarities.

2) Check the dramatic differences in germination at the tips.

3) Check that the assembly meets K Sh Ph.

4) Check that above the pot on the left in the diagram, we have the right schin, and that at above the pot on the right we have the reversed schin.

Conclusion: It is a dangerous assembly because we detect K Sh Ph with Sh on the whole assembly - editing must be thought of as a single form and not as an association of shapes that would be: the piece of wood, the solenoid, the flowerpots.

I. *Broadcasts from another*

Jean de la Foÿe noticed that the autioth taken separately emitted from one point.

Let's see some autioth:

c	C	/	B	*	and	I		
Sh	Sh	H Y W D R Ts	M final					
300 300		5	10	6	4	200	90	600

Note: The eifs come out where the arrow indicates

Remarks :

- an aut can emit several eifs at the same point.
- If the autioth are in a word, the emission points are not necessarily the same than on each aut taken separately.
- When we consider a word, what it emits depends on the representation chosen.
 - or we are looking for a specific meaning of the word.
 - or we consider the word and the nebula attached to it.

II. *Equivalence levels*

The levels of equivalence appear during the rational representation of the different reigns. We have for example:

- mineral
- vegetable
- animal
- human

Jean de la Foÿe, who had established them, presents them in this way to associate them with the eifs.

- Eifs "in physics" characterized by H h A R Ts
 - pronunciation: Haaretz
 - a meaning: the Earth
- Eifs "in vital" characterized by L N Ph Sh cH Y H

pronunciation: laNephesh Raiah 1

1 Here it is an eif which is from the NE

a meaning: divine breath

• Eifs “in spiritual” characterized by RWcH

• pronunciation: Rouah

• a meaning: Spirit

Exercise: Find the emission points of the eifs on each aut.

Exercise :

A circle is drawn on a sheet of white paper. In the central part a schin is placed.

We impose the NF

Check that the undifferentiated spectrum is detected around the circumference of the circle.

Response :

Remarks :

If we put the schin upside down what happens? We does not have the same thing because it was necessary to impose the N.F..

So the Eifs are going to be of different types - they will be at "equivalence levels" different-. They will have different characters according to equivalence levels.

We will also see later the statements on the forms and

the eifs. Similarly, the same eifs may be in different states.

Equivalence levels and states are very important. We will see this in the following presentations.

Exercise :

Realize the cylindrical pendulums on which are carried in square Hebrew the words:

HhARTs

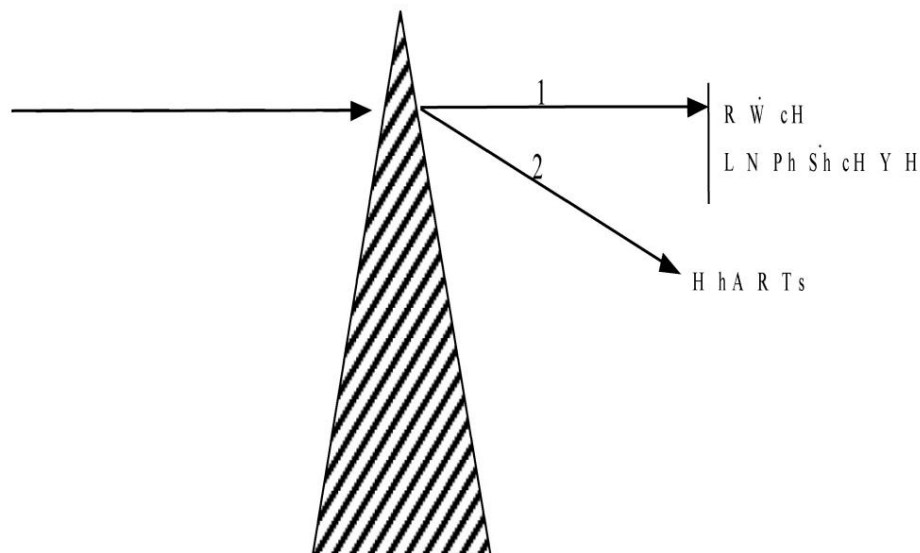

LN Ph Sh cH YH

R WcH

Exercise :

We give ourselves a wooden prism.

We send an eif on this prism

Assume the eif at 3 levels of equivalence.

1) Check the output equivalence levels as shown in the figure.

2) On the path of 1 we place a witness of living plant or animal.

- a) Check that the LN Ph Sh cH YH part is stopped.
- b) Check that the part in RW cH continues.
- c) Verify that RWcH is intercepted by a living or dead human witness.
- d) The H h A R T s part always passes.

Notes: In RW cH:

- a) we can have troubles for example saturation of the devices.
- b) if an eif is emitted by a very fine needle, it is, at this level of equivalence transformed into a brush.
- c) If a V+m is in this state of equivalence, we do not detect V+m but an undotted W. In the particular case where the $V+_M$ is emitted by a needle, we finds the VV very close to the axis but it is never very clear.

The RWcH "locks us up" in a domain where we risk no longer being masters of phenomena or detections.

Forms that emit at all 3 levels are mostly depolarized.

They are qualified as "magic" because they make the pendulum K Sh Ph react at the place or at the reverse as well as the pendulum

DRY Sh H hAL HMThYM

We put the dot in the middle of the schin in order to have an answer.

These three words mean: communicating with the dead, necromancy.

Forms that respond to this are said to be "incomplete". For Jean de la Foÿe, they would have a void to fill.

If we pass an emitting form like "tree trunk" to the level of equivalence"

RW cH or if it responds to K Sh Ph, then the polarized body rotates 180° causing the eif

Vj passes to the west and eif R passes to the east. In this case often the pendulum Sh TN (Shatam) also responds. We cannot guarantee that this is always true because in this area we finds exceptions very often. Naturally if the person imposes laws, he find. As we have already pointed out, it is richer not to impose anything a priori in its representations.

III. The states

To forms, to eifs, we can make states correspond.

These states are the transposition of the concept of state that we usually find in these forms, eif. We are talking about the state of a person, state of health, fatigue, the state of a system in rational mechanics.

The states are generally delocalized; and even in everyday life, the state of a person who will say "I feel good" is not measurable. It cannot be compared to that of a another person who will pronounce the same sentence to speak of themselves, of their condition. By against the same person will be able to talk about the improvement of his condition; this state is little localized by these last two remarks. And yet we talk about it in the usual C. de C.!

Effectively in the usual C. of C., as we have already pointed out, concepts linked to the global are used. It is necessary to become impregnated well that because of the discipline of spirit necessary to the elaboration of the knowledge of the forms and the expansion and the richness of this knowledge, it is necessary to remove from rational thought a certain number of concepts that seem anachronisms in the society in which more and more we we must immerse ourselves, a society where moderation becomes necessity. It is an approach that

to displace certain sensations and use them as a directional support for the construction of Consistency fields.

Thus the usual C. of C. becomes its exhalation. He is more and more what we see in him. In this sense it is inhuman.

We saw at the beginning of this chapter for the first time the term transposition to designate ! , use of a word, in this case that of status, in a context where it did not exist. Rather than to create another word and moreover the process used which is that of transporting a concept from one area to another, an enriching movement, we take concept "walks", but directed walks, not wandering - in the latter case this too is very rich -.

So we are now going to talk about the state; the state of a form, of an eif. In these cases the states will be completely relocated.

We will characterize them by Hebrew words, written in square Hebrew, carried on pendulums cylindrical. But states will be marked otherwise.

Thus we find the state K Sh Ph - to avoid repeating the word state we will write $| K Sh Ph \rangle$ but warning: the $| \rangle$ should above all not be worn on the pendulum; inside $| \rangle$ we put square Hebrew -.

It is necessary to add $| KShPh, Sh \rangle$ which specifies the state even better; we will also have

$| K Sh Ph, Sh reversed \rangle$ and again $| K Sh Ph, Sh reversed, Sh TN \rangle$.

All this avoids speaking of "good", "bad" states, which is very poor and does not correspond not the field we are gradually entering.

When using a shape or a system of shapes you have to look at the levels of equivalence and states. Without that, we are no longer masters of what we do and of the serious consequences can occur, consequences which, sometimes, are not metrizable.

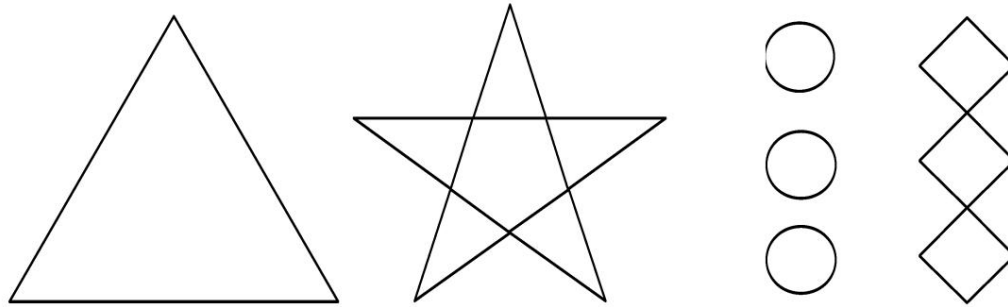

All states such as $| K ShPh \rangle$ and those containing this character warn that we may be faced with unpredictable phenomena.

Note that to identify certain "magic" states, it was necessary to add dots • or holes o to

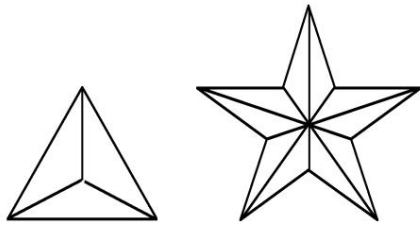

$| K Sh Ph \rangle$; thus we find: $| K.Sh.Ph. \rangle$ and $| KoShoPho \rangle$ and there are still others.

Exercise :

1) Check that the 4 shapes correspond to | K Sh Ph >

2) That these two forms do not correspond to | K Sh Ph > ni even magic with characters additional.

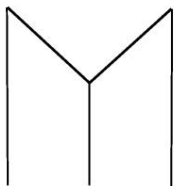

3) That both forms respond to | KoShoPho>

O

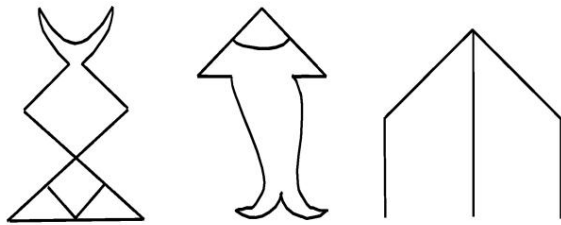

4) That the form responds to | K.Sh.Ph.>

5) That the form of Yin Yang responds to a magic called "Ying Yang magic"

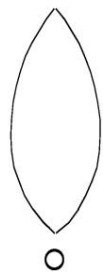

6) That the three forms respond to other "magics"

Remark :

- The following question "Are there several types of "magic"? is raised here.
- You shouldn't see magic everywhere; in Berry witchcraft, for example, we find many states | K Sh Ph, reversed Sh >.

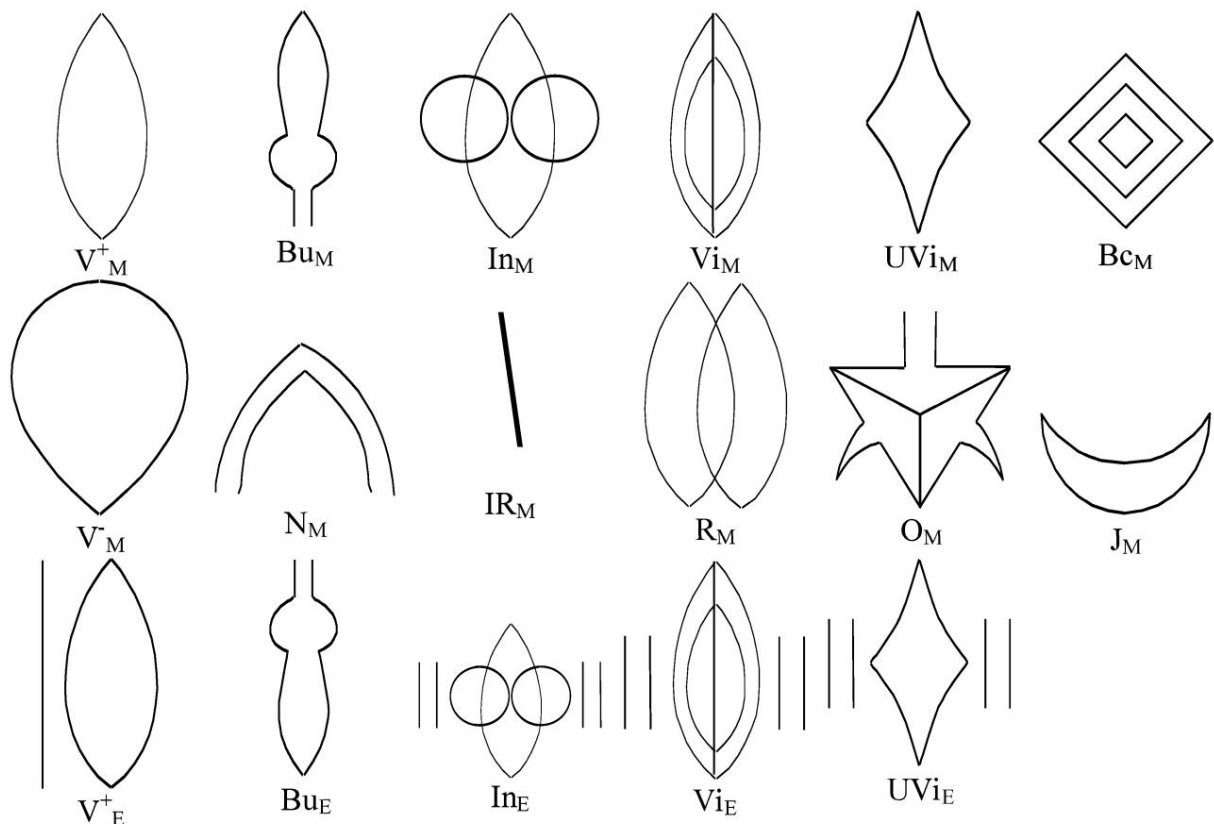

We will see in exercise some colors of the differentiated spectrum.

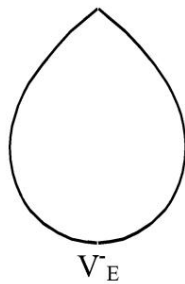

The shapes given below are always assumed to be oriented at NF; by example opposite.

We will therefore put the white and black circles to impose the NF. The eifs are detected in the plane at the end of the shape placed at NF.

On the other hand, about autoioth, we do not need to orient to NF.

Re

Oe

Note: Detection always at NF and in the plane.

Exercise :

A rectangle of sides 6 and 10 is given. The unit of length is not specified.

1) If we say "in the center, we detect the node of life!" »

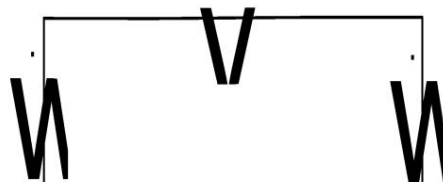

- a) Is it true ?
- b) Is it always true?

2) Because we didn't talk about unity, we could have chosen 5 and 3 as sides.

- a) Check that, taking as unit of length 32 mm, a rectangle of sides
 3×32 mm = 96 mm
 and 5×32 mm = 160 mm does not have the life node in its center
- b) By vs a rectangle from side
 6×32 mm = 192 mm
 and 10×32 mm = 320 mm has the life node in its center

3) At 10 and 6 it corresponds respectively to Y and W.

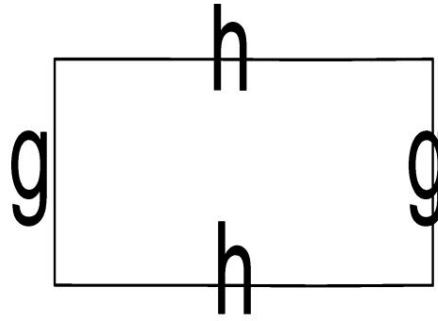

- a) What can be detected in the center of the figure
 opposite where the sides are like 10 and 6 -
 and this whatever the unit - ?

xt

At 5 and 3 it corresponds respectively H and G.

b) Is the life node detected at the center of the figure opposite?

Answers:

l)a)Yes b)No

- 3) a) We detect the node of life
 b) We do not detect the node of life

Remarks :

- In this exercise, we are confronted with the problem of unity. When 6 and 10 is 6 n and 10 n where n is a unit. If we think of 6 n and 10 n above we will detect the node of life in the center whereas one will not detect it if one thinks 3 n and 5 n. But we saw that if $n = 32 \text{ mm}$ for example - other cases are possible - we are sure to find the node of life when we can very well not find it while doing 6 n' and 10 n' where n' is a unit fraction of a meter for example.

Let us point out that an Egyptian cubit makes it possible to have the node of life on this rectangle.

This goes even further but we will not discuss it in this course.

Moreover we saw that to 10 we had matched Y. It is no longer 0 10 as we have

presented in the previous booklet. And even at 6 we matched W and not the 0 0 6

etc... It seems that we are returning to the usual interpretation. It must then be understood that

alone is linked to a number, it contains the value of the number, but it expresses associated with other autoth or in some circumstances games related to this value, in this case

by the construction of the sequences obtained by additions between numbers.

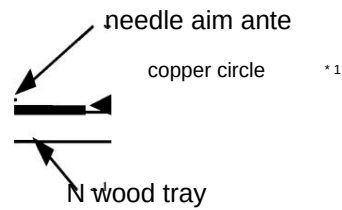

One of the two Egyptian cubits allows for the rectangle of sides 6-10-610 to obtain the node of life in the center.

**"The world will not be saved,
if it can be,
only by rebels"**

Andre Gide2

Exercise :

Consider a magnetic needle placed on a round wooden tray; the pivot of the needle is placed with the center of the board. The tray supports a copper circle.

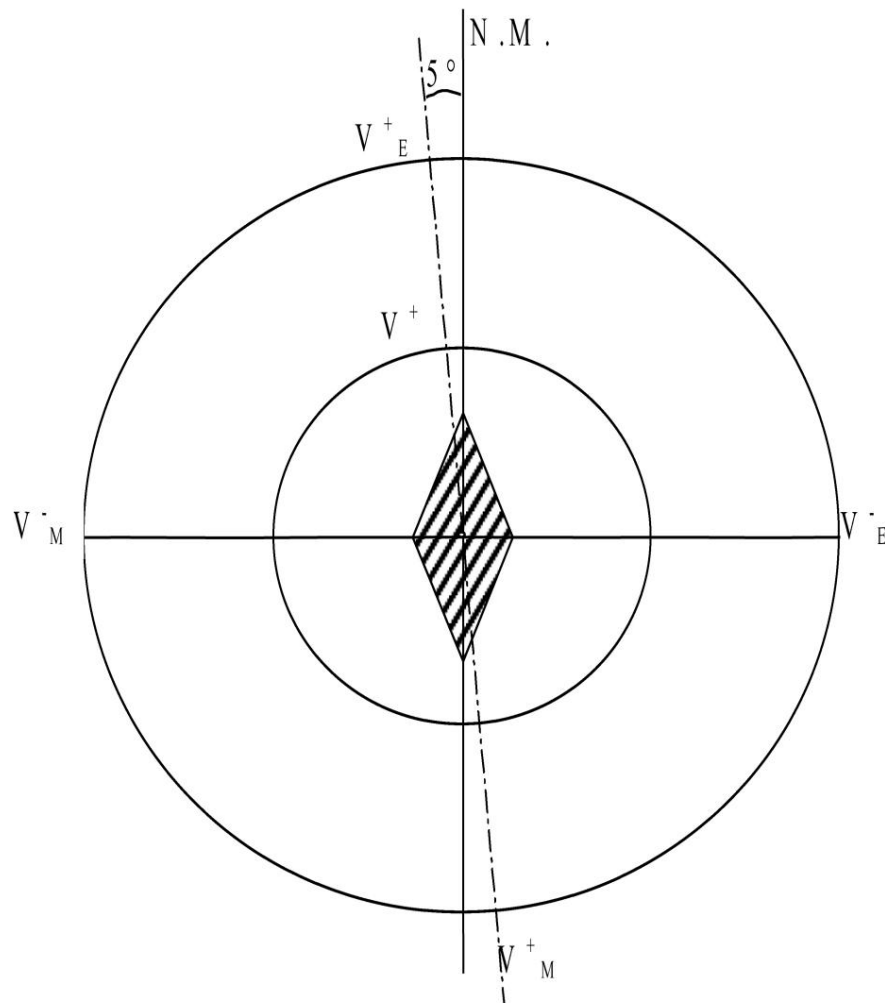

Check, if the needle is well placed in magnetic North, that:

- 1) On the copper circle (of radius R) the spectrum of the polarized body is detected - this without artifice -
- 2) On a concentric circle of radius $2R$ - not shown - the aura is detected - this without artifice -.
- 3) The usual + and - polarities are detected
- 4) That everything is deflected 5° to the west with respect to the axis of the needle.

Advice: do not forget to drill the plate with a diameter $>2R$ in the center right through.

- 5) The vital field is detected with the schin above.

From where one produces eifs starting from the magnetic polarities. If we replace the copper needle - on the transmitters that we will see later - by a magnetic needle, we must take into account the 5°.

- 6) If we place a bar magnet vertically, magnetic north up, and we places on it a wooden tray with a copper circle of radius R , the tray having a radius $> 2R$, then we check the same thing - The assembly corresponds to one of those of the Baron de Reichenbach - (the tray as before must be drilled).

IV. Special study

Consider two circles with common center O , radii R and $2R$.

Suppose the circle of radius R is a polarized body and the circle of radius $2R$ is an aura.

Let us draw as in the figure above the circles of radii $R/2$, $R/4$, $R/2n$ (integer n positive). These sets of circles correspond to an approach to the vital field whose 4 components are auN.F., SF, OF, EF

By drilling a hole in O, from side to side, allows work at the level of equivalence

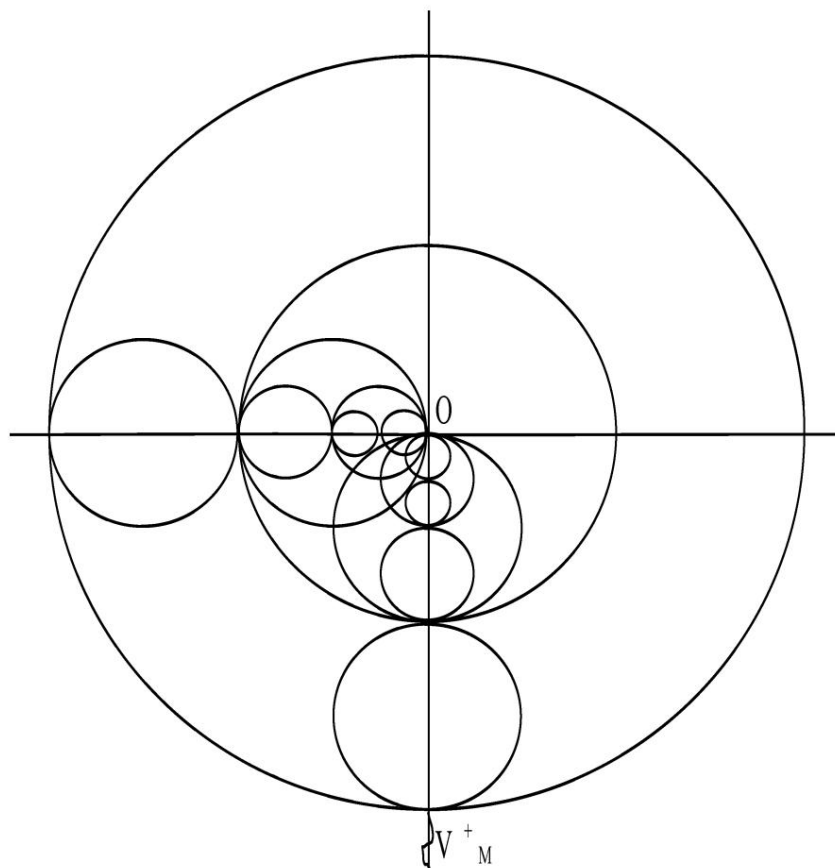

"physical" ie H hA R Ts and avoid RWcH.

Here there is no need to impose the NF.

It is in the circles which pass through O that we draw the new circles. We could do the same route in the others but that would bring nothing new.

We can therefore make a round wooden tray, drill it in the center, trace the families of circles of radius $r = 1/2$ ". By placing in the center a needle of radius between R and $2R$ we detects the eifs of the differentiated spectrum and with a needle of radius $< R$, we detect the eifs of the undifferentiated spectrum.

The eifs are for each of the spectra emitted at $V+m$

Remark :

The more circles of radius $1/2$ ", i.e. the larger n is, the greater the eifs are "powerful".

Naturally it must be understood that here the word powerful means that one detects further wooden disc; the eifs being completely delocalized, there is no intensity which be associated.

V. The Fitness Field

Introduction

This experiment was set up by Jean de la Foÿe to designate a field associated with a form he called "Physical Field". He is at the level of physical equivalence - H hA R Ts. It is often mixed with the vital field.

Conditions for obtaining a good physical field

Let's start with a wooden disc placed on a material support which will represent the structure of the field physics - what we will see later -, he must have the polarized body, the aura, perform the separation of polarities, all with an orientation with respect to the support and not by compared to the natural magnetic field.

If a pencil is placed on the disc, the point at the artificial south and the other end in the center, it will have to emit an eif from the aura - if its length is sufficient -.

To set up the physical field Jean de la Foÿe started from the name of God - finally a names of God -: YHW H. He took the correspondence between autioth and numbers and regular polygons which gives:

and 10 decagon

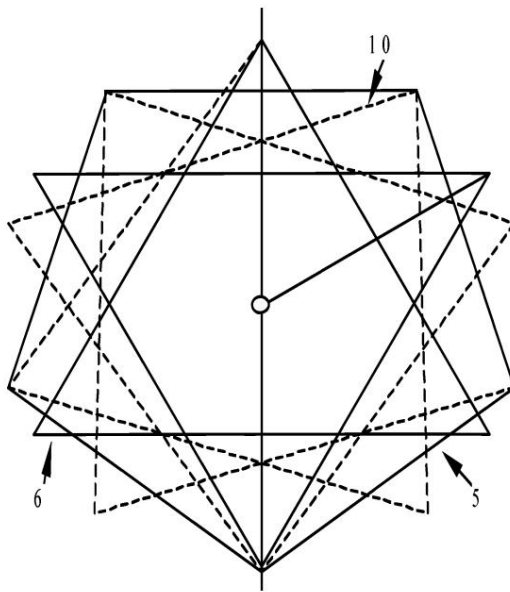

H 5 Pentagon

In 6 hexagramme

H 5 Pentagon

He gives himself the circle as the unit.

Consider then a circle with center O

Let's draw with as circumscribed circle:

the hexagon

the starry decagon

the convex pentagon

We pierce the circle from side to side in the center

Then we erase this circumscribed circle.

We draw the half-line of the UVi!, which necessarily orient the field.

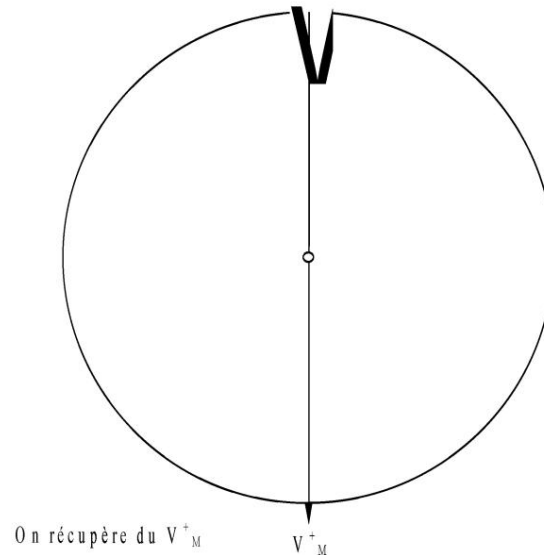

**We can add the star pentagon but
it adds nothing.**

If we put a pencil on this figure with the point at the artificial south and the other end in the center, it will emit $V+m$. If we rotate this pencil while always keeping the same end in the center, in the artificial south, the eifs of the aura will be detected.

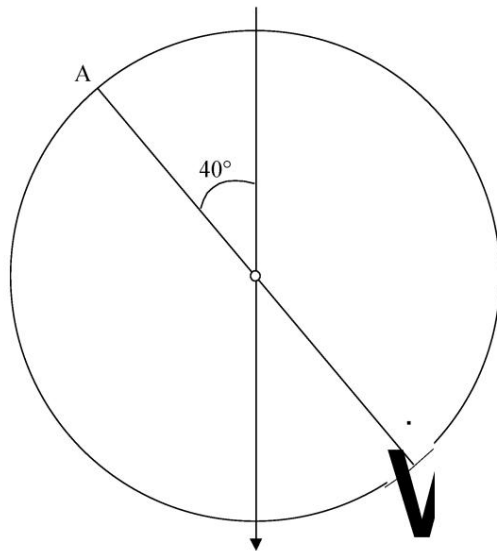

Back to the circle: We consider the

Oh up. Let's place the Yod on the upper intersection of the circle with vertical diameter. Let's pierce the circle centre.

We detect the V_M^+ downstairs.

On récupère du V^+_M

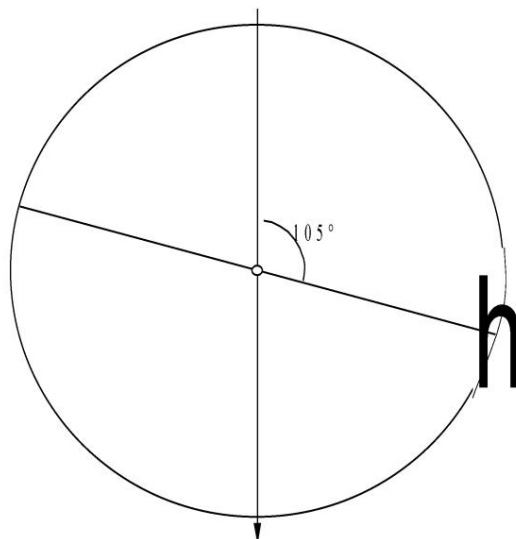

On récupère l'eif indiquée en A

The diameter is drawn as in the figure, at 40° from the vertical diameter and we bring the Waw pointed to the above.

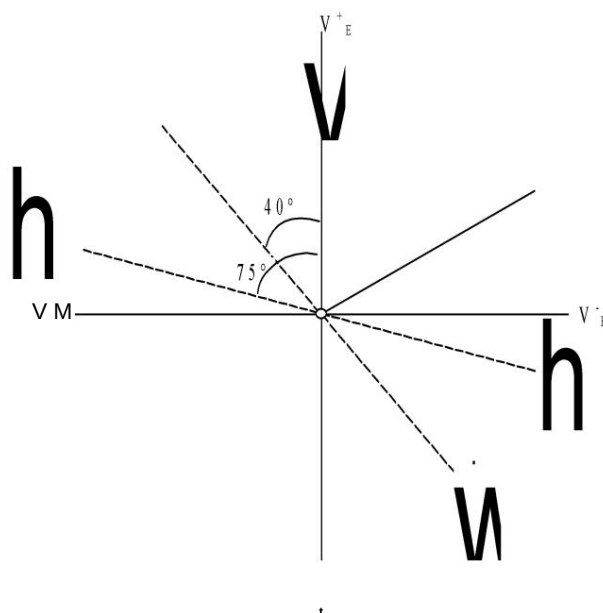

Attention, the location of the aut on the drawing is fundamental.

The letter A is not to be marked on the diagram; she does not serves only to give an indication.

Ici on récupère du V_E

We draw the diameter as in the figure, at 105° of the vertical diameter and we carry the Hey.

Let's make the 3 diagrams in one; and eliminate the circle.

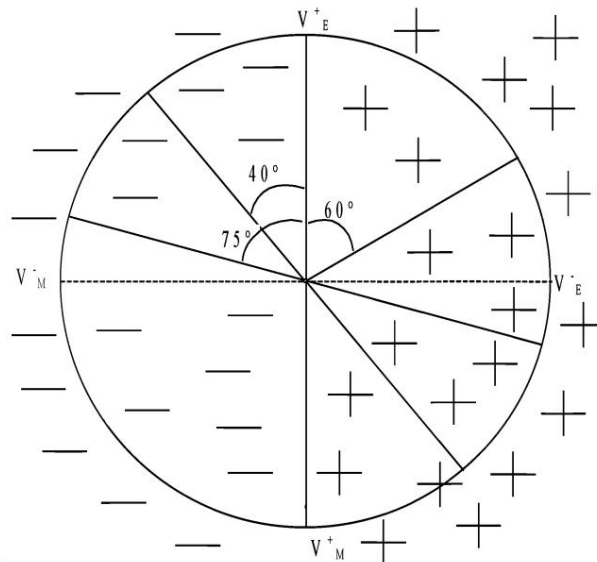

- We double the Hey
- We do not need to impose the NF
- We drill in the center.
- We draw the horizontal diameter
- We find the vital field, that is to say that in particular we have the GD to the west and ItCXDIthere is.

One sees appearing what one calls the directing axes of the field of form.

Consequences :

1) which means that if we remove the Hebrew characters we obtain the means to have the field physical.

2) Let's draw a circle that we drill in its center.

Le N.F. est imposé.

En traçant la $\frac{1}{2}$ droite à 60° du nord artificiel (N.F.), on oriente le champ, sinon il faudrait imposer the NF.

5) Here it is only about the differentiated spectrum.

6) If we draw the V'' axis (V_{ye} , V_{ym}) the vertical above the center is + and the V axis+ (V_{+and} , V_{+M}) is +.

A control must be treated on a + axis so in this case it is preferable to draw the V axis.

- the circle is erased.
- the spectrum of the polarized body is only detected by placing a concentric circle of radius $R/2$ with a needle $< R/2$ - if R is the radius of the starting circle -. We must therefore use a needle of radius r such that $r < R/2$ if the differentiated spectrum is to be detected.
- We can leave the circle of radius R , this does not interfere with the eifs.

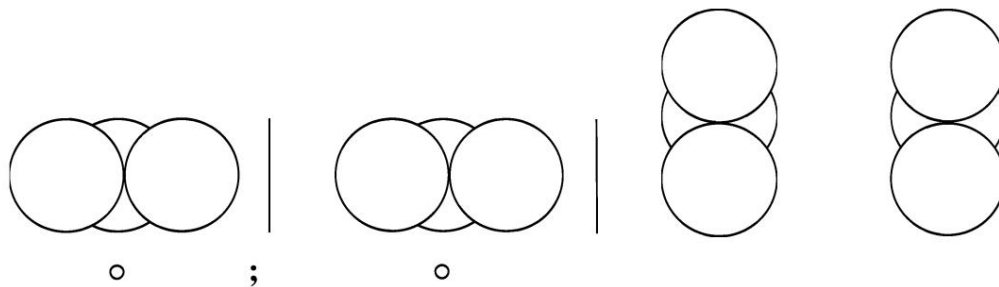

Remark :__

This scheme is not emitting as well; we gave it to put in mind the provisions eifs of the differentiated spectrum. The small central circle is worthless.

At one place we see on a radius "Chartres". This is the so-called eif of Chartres - in memory of Chartres cathedral where Jean de la Foÿe had discovered it He designated it by $Z+m \cdot He$ also exists $Z\ddot{y}m$

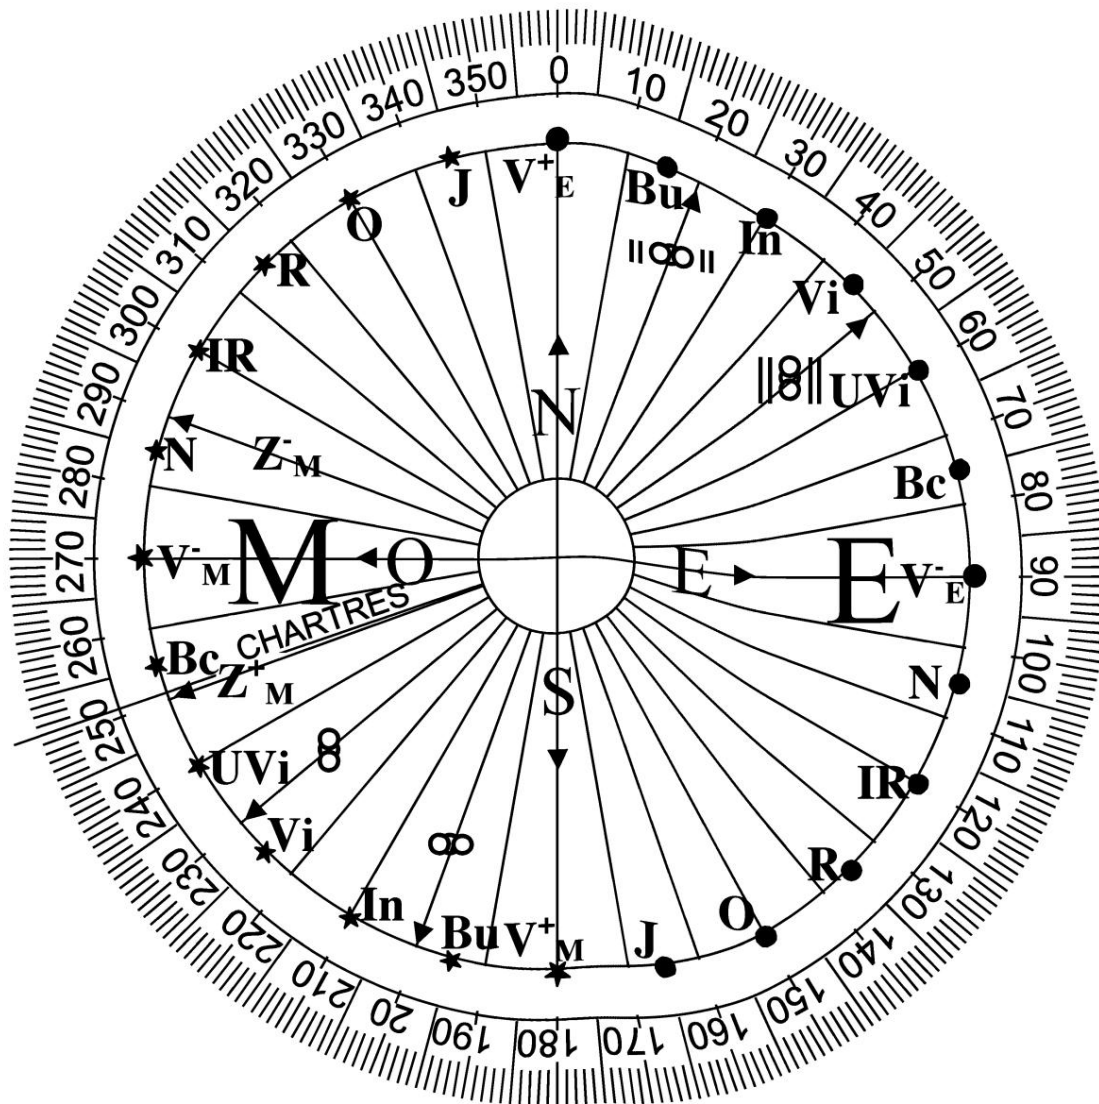

Are also carried on 4 rays, respectively the 4 forms characterizing the vital field.

The associated eifs correspond to what these forms placed at N.F. emit, that is to say:

By symmetry with respect to the center we have Z_+ and $Z\ddot{y}E$ respectively.

There are the eifs of the undifferentiated spectrum Z_+ and Z' .

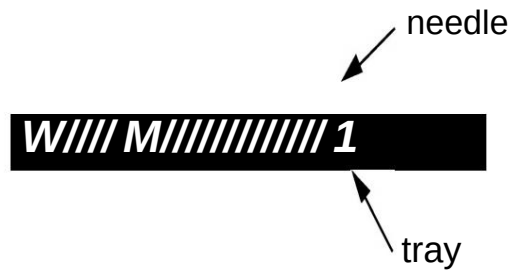

Jean de la Foÿe, starting from YHWH managed to build a field — Physical field — which has the interesting properties of generating the 2 undifferentiated and differentiated spectra.

God's name is not always YHWH; it is enough to consult the Torah to be to convince.

By using other words, other fields are possible which do not give the eifs of the tree trunk.

The emitting plate of undifferentiated and differentiated spectra

We will make it in 3 cm thick wood, pierced in the center right through. We make two very sharp copper needles, one of radius r and the other of radius $2r$.

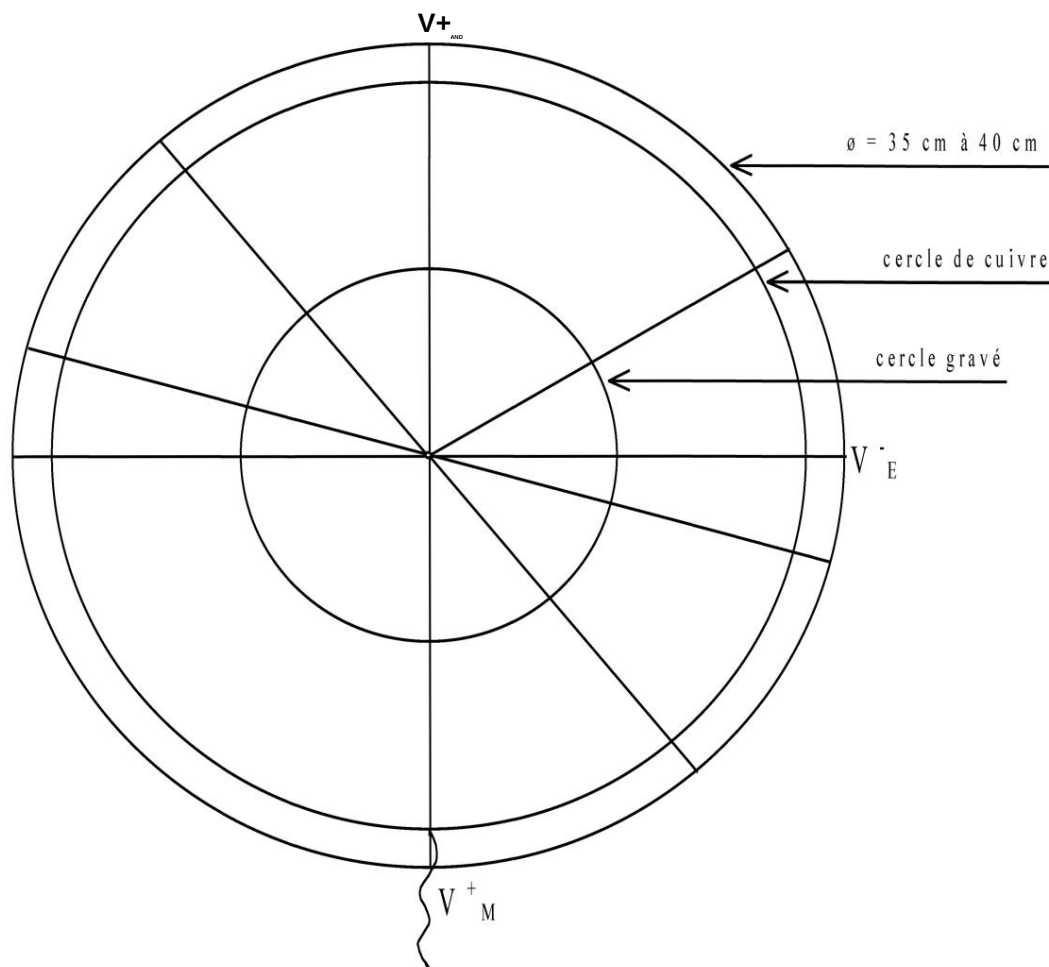

The board is circular; we glue a circle of copper wire of radius $2R$ such as $2R$ slightly less than the disc radius.

Then we burn the physical field to disk.

At $V+m$, we weld to the circular copper wire a finer wire where we will detect the eif indicated by either needle.

We carry on the edge of the disc angles of 10° in 10° , the 0° at the top as well as the 24 eifs of the differentiated spectrum and the 12 eifs of the undifferentiated spectrum on the circle of radius R . We will always operate with only one needle.

On a $r < R$.

Erratum du 5, eme fascicule (page 2)

The FFV is composed of 3 segments OA, OB, OC such that OA is vertical,

OB=OC and the angle BOC =120°.

The angle of OA with the plane BOC is equal to 33°.

OA = $V!$; x OB where $V!$; is the Radian number

$v)!$ ~1.324...; we can take 1.32 as a value, the form will be correct.

Paper 7

July 97

*I. The eifs of the undifferentiated spectrum and the differentiated spectrum
Forms called "canons"*

It is a wooden stick, circular or square in section.

Let us see for example the Hebrew words which mean to live, to exist ^{cH YYM} ~~ang~~_{10 10 600} which means life, food, sustenance.

Note: For 8 10 10 600 we will take 8 10 10 24 (explanations later).

Let us wear on a stick 8, 10, 5 or 8, 10, 10, 24, grooves allowing to place the lengths 8,10 etc...

C 3 J
8 1 0 5

The unit can be arbitrary.

We hold the stick at one end - the one of length 8 - and we point it at the plant to detect; that for which it is necessary to employ an artifice.

It is these two types of sticks which will intervene for the approach in the study of a plants.

So remembering what we said in the first papers about the detection of the polarized body or the aura of the tree trunk, one can:

- either press the thumb of the free hand on the folded little finger, the hand pointing towards the plant,
- either hold a point of any leaf between the thumb and the index finger,
- either lean the plant if possible,
- either take a baton and place it in a circle where the NF - SF has been imposed.
- or finally hold an 8+10+5 cannon
- or an 8 + 10 + 10 + 24 cannon

About the cannon it is necessary:

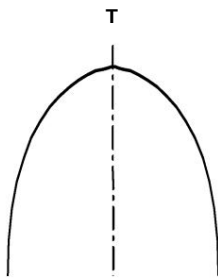

- hold it by part 8,
- orient it by tending it towards the NF.,
- otherwise, we can ignore the orientation and wear:
 - on 8,10, 5 the autioth cH, Y, H or
 - on 8, 10,10, 24 the autioth cH, Y, Y, M.

- one is obliged, for the realization of certain sticks, if one of the finals is K, M, N, Ph, Ts to count it as if it were not in the final. Note: on the Letters table numbers, the numbering is 10, 20, 30... starting from 10. Here we will count 10, 11, 12...
- To avoid the orientation of the NF of the stick, it is possible to plant vertically in certain grooves a small copper nail.

It is seen that the handling of the sticks must be carried out with caution.

Problem: We consider an emitter of Bc (undifferentiated). We send it by a wire on a wooden prism.

1) What do we observe on the other side of the prism?

2) We build a form in copper wire, for example as shown opposite (warhead) and place the NF on the axis above. What do we observe in the axis inside?

3) The detected eif is called according to the terminology of Jean de la Foÿe: eif of Chartres (it is detected under a vertical warhead). What is she doing on the eifs of the undifferentiated spectrum?

4) It is sent on a wooden prism. What do we observe on the other side of the prism?

5) By an appropriate assembly, it is combined with the undifferentiated Bc. What do we get?

6) Does an ogive of this shape give the eif of Chartres?

j 7) We carry out the assembly below, that is to say 2 warheads having the same

/ \ axis. We imposed the NF. Do we still have the Chartres eif?

/

o

8) What are the M and E components? The component M is detected with the form

placed on a cylindrical pendulum. The component E with the form

The Hebrew word (found by Jean de la Foÿe) corresponds to the eif of Chartres (Haretz) the hA R Ts?

Ts R ha

{ r And

final Tsâdé Reisch Aleph

27 (900) 20 (200) 1

Reminder: Hebrew is read from right to left.

Here the Ts, although final, is counted normally (27 and not 18).

Build the corresponding cannon. Check that oriented NF-SF it emits the Chartres eif - the

hold by the side of the hA ·

Can the barrel be made direction independent?

Answers:

1) We find the undifferentiated eifs.

1. The first step is to identify the problem or question that needs to be answered. This involves understanding the context and the specific requirements of the task.

1. Welche der folgenden Aussagen sind richtig (R) oder falsch (F)?
 a. Die Kosten der Beschaffung sind unabhängig von der Menge.
 b. Die Kosten der Lagerhaltung sind proportional zur Menge.
 c. Die Kosten der Beschaffung sind proportional zur Menge.
 d. Die Kosten der Lagerhaltung sind unabhängig von der Menge.
 e. Die Kosten der Beschaffung sind proportional zur Menge.
 f. Die Kosten der Lagerhaltung sind proportional zur Menge.
 g. Die Kosten der Beschaffung sind unabhängig von der Menge.
 h. Die Kosten der Lagerhaltung sind unabhängig von der Menge.

1. The first step in the process is to identify the problem or goal. This involves understanding the current situation and what needs to be achieved.

1. The first step in the process is to identify the problem or issue that needs to be addressed. This involves gathering information and understanding the context of the problem.

1. The first step is to identify the problem or question that needs to be answered. This involves understanding the context and the specific requirements of the task.

and AB. We pierce the plane in T. We see immediately that $(Tx, TM) = 105^\circ$ $(Ty, TM) = 60^\circ$ and $(TM, Tz) = 40^\circ$.

- 1) Observe that both inside the triangle and outside there are no polarities or
Champ Vital
- 2) Draw the line parallel to BC passing through T. What do we observe?
- 3) We draw the circle circumscribed to the triangle ABC and the circle with center T and radius CT. We
can observe that the figure emits what are called Arkhams and Mahkras¹. On
removing the triangle ABC, we still have some Arkhams and Mahkras.
- 4) By taking a pencil placed on the plane, the end not sharpened in T and directed along a radius (the
length of the pencil greater than or equal to CT), it emits the eifs of the aura to the SF.
- 5) Can we have the undifferentiated spectrum?

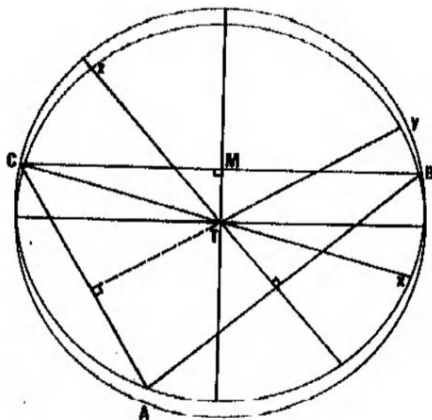

Answers:

- 3) There is a Vital Field. The portion of the plane to the left of CA and delimited by BC and BA
prolonged is negative. The portion of the plan to the right of BA and bounded by CA and CB
prolonged is positive. Ty in the sense of Ty is positive in a portion that begins
a little outside the triangle ABC.

- 5) Yes. If you want to have it with the same needle 11 you have to take it shorter or
equal to the length less than or equal to TM.

Consider the homothetic triangle of ABC, in the homothety with center T and ratio

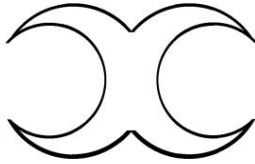

V2. One can have an undifferentiated eif with a needle length less than or equal to
the length of the segment carried by the ray coming from T and of which one end is in T and the other
obtained as intersection of this ray with the side of the homothetic triangle of ABC
in the dilation mentioned above.

¹ This will be seen in the 21st year course

Problem :

Consider the shape consisting of two crescents joined in the back. It corresponds to an eif2.

Make a cylindrical pendulum on which it is carried on the side surface.

- 1) Check that this eif is undifferentiated. Give the precise angle of emission when using the transmitting disc.
- 2) Check that we find Z+ on the star of David whose highest vertex is pointed at above, the fleur-de-lys of the kings of France, the Hermine of Brittany.
- 3) If the Star of David is vertical, not pointed, is the Z+ detected and where? If the lily flower, the ermine of Brittany are vertical in usual gaze position can we detect the Z+ ?
- 4) If these shapes are in a horizontal plane, how to get the Z+ ?
- 5) It corresponds to the Hebrew word DBR (Dabar)

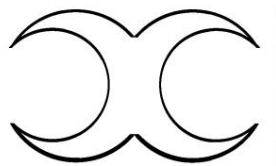

R B D

F 11 d

Reisch	Beith	Double
20 (200)	2	4

Make a cannon 4 - 2 - 20; find by which extremity one detects Dabar. (Do you have to orient

NF?) If so, what can be done in the canon to impose the NF?

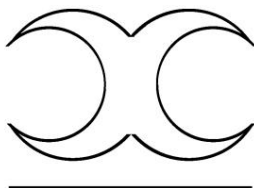

6) Le Z + _{AND} matches the shape

tray transmitter ? Same question for the m who

. Where do you find it on the

matches the shape

**"He who does not shout the truth
when he knows the truth
becomes an accomplice
from
liars
and
from
counterfeiters! »**

Charles Peguy³

³ Charles Péguy (1873-1914) born in Orléans - He entered the Ecole Normale Supérieure where he had as master Bergson - He died on the front on September 14, 1914.

II. **eifs** "Amplifiers"

Remark

First of all let us recall that the eifs not being localized, to speak of amplification has no senses. There is no "greater than" or "less than"...

Yet effects on living beings can be compared, for example the disappearance of a evil: we can measure a shorter duration.

Thus we will say that the eif or eifs used were "more intense". But it's an excess of language.

And the pendulum will be taken as a convention that it rotates faster than the sensation at the wrist is more brutal when it is "stronger".

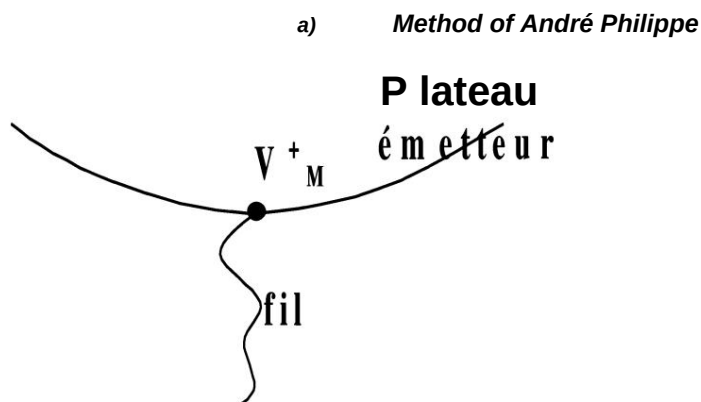

You always have to know what you are doing and question tacit knowledge.

Ways to "amplify"

We will only name a few.

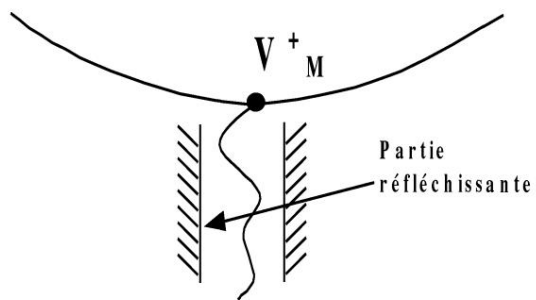

The undifferentiated and differentiated spectra are considered in the eifs.

Care must be taken to ensure that the amplification process does not change the nature of the eif, nor its state.

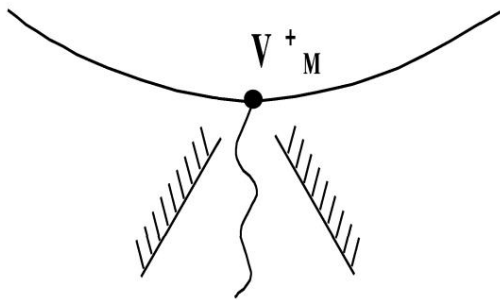

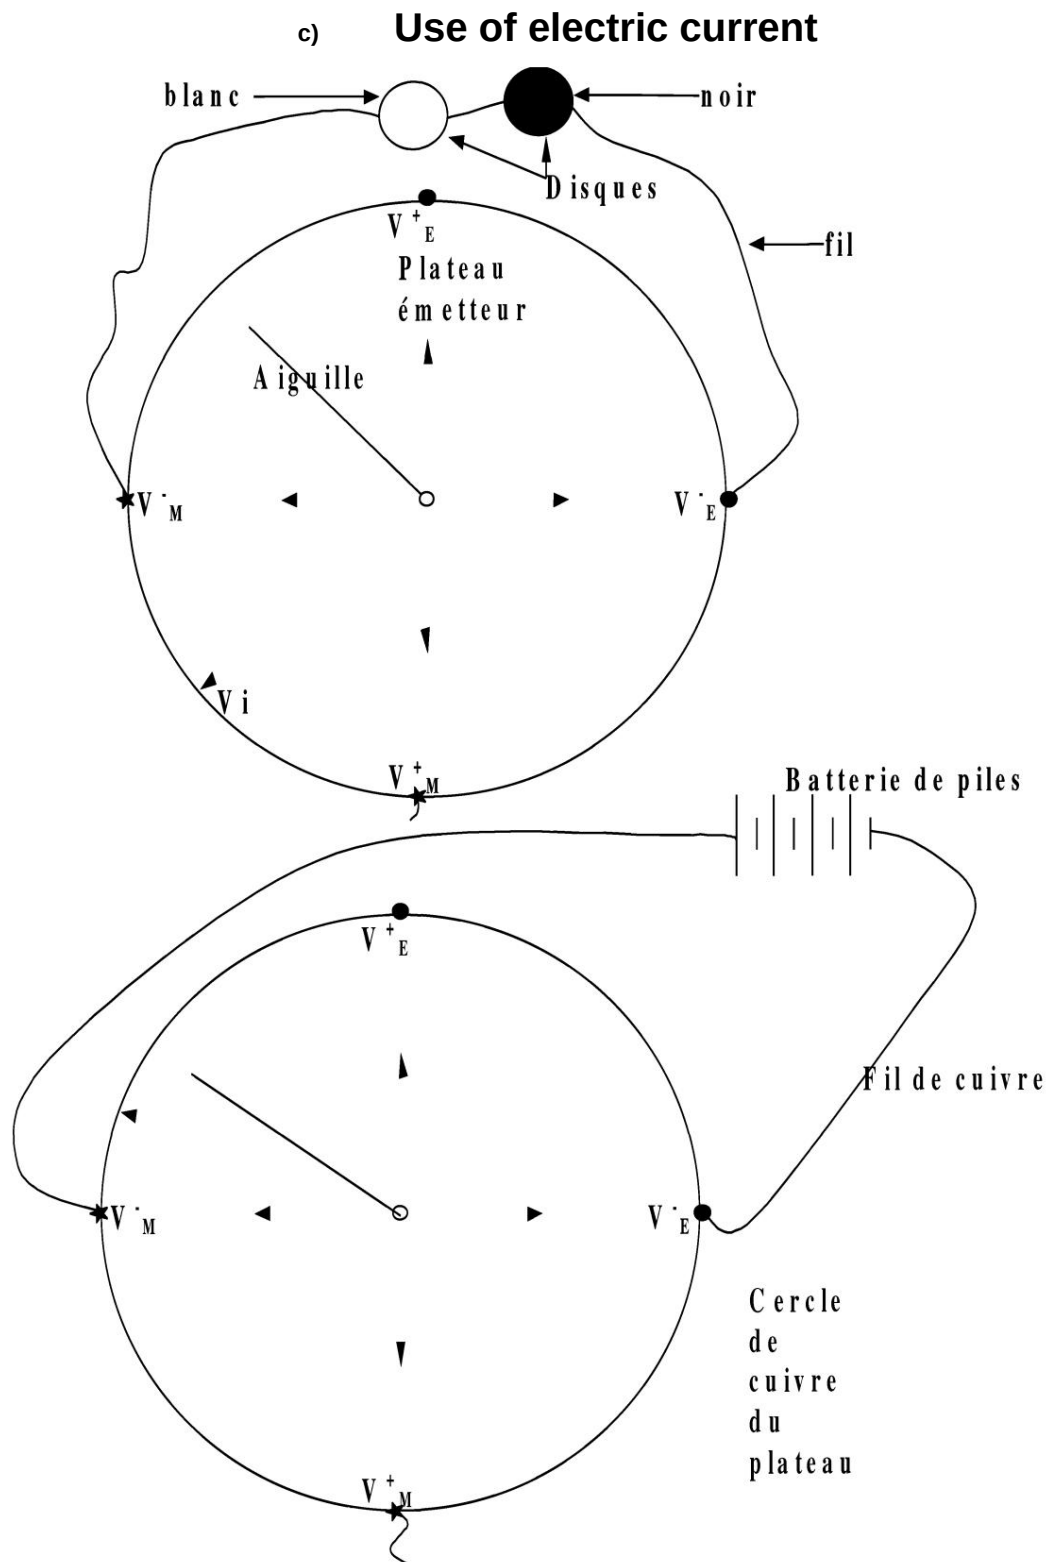

André Philippe had the idea of placing a magnifying glass on the output wire, i.e. a lens biconvex. The larger the lens, the stronger the amplification.

b) We place the wire between two parallel mirrors

The mirrors can have a certain angle between them.

En V_M^- et

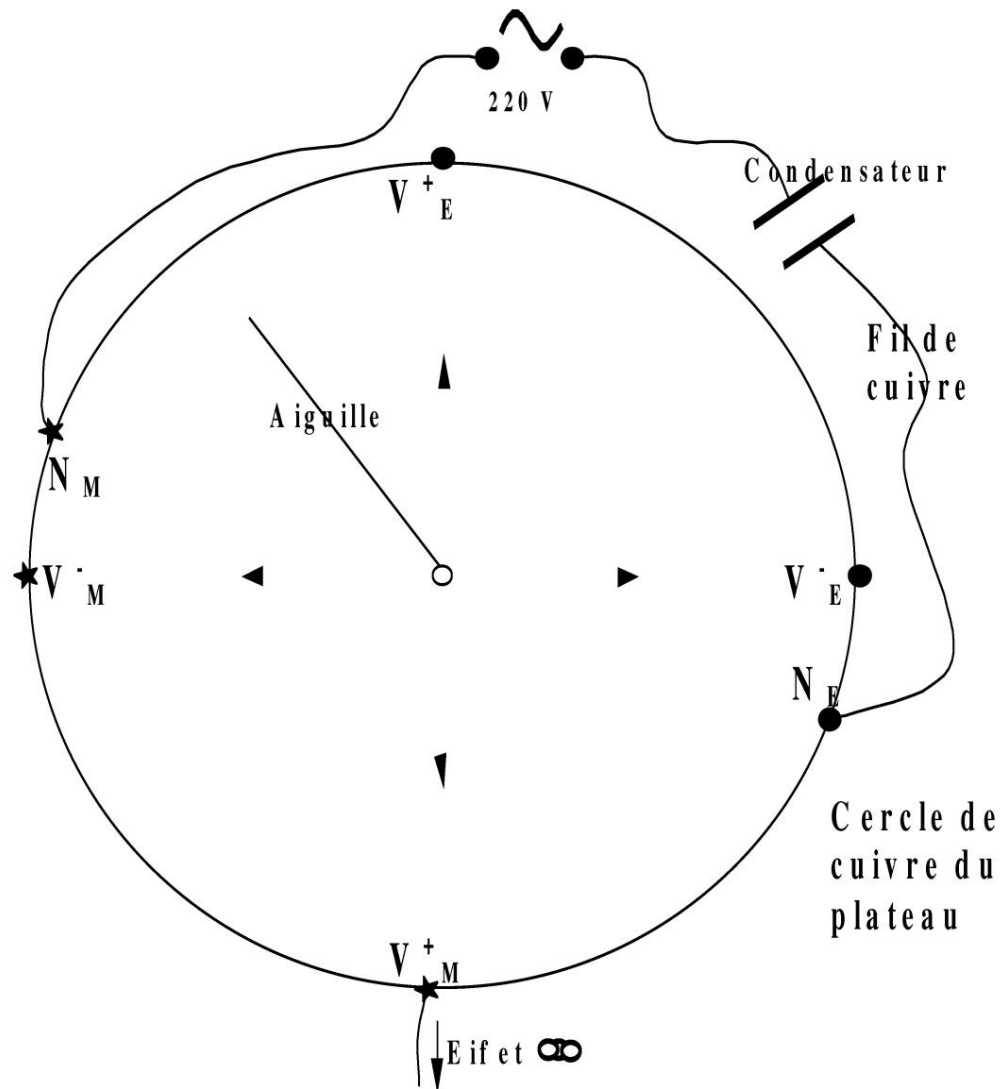

V_E the wires are not soldered to the copper wire but a small insulating sheath separates them into these 2 points of the circle.

The higher the battery voltage, the greater the amplification.

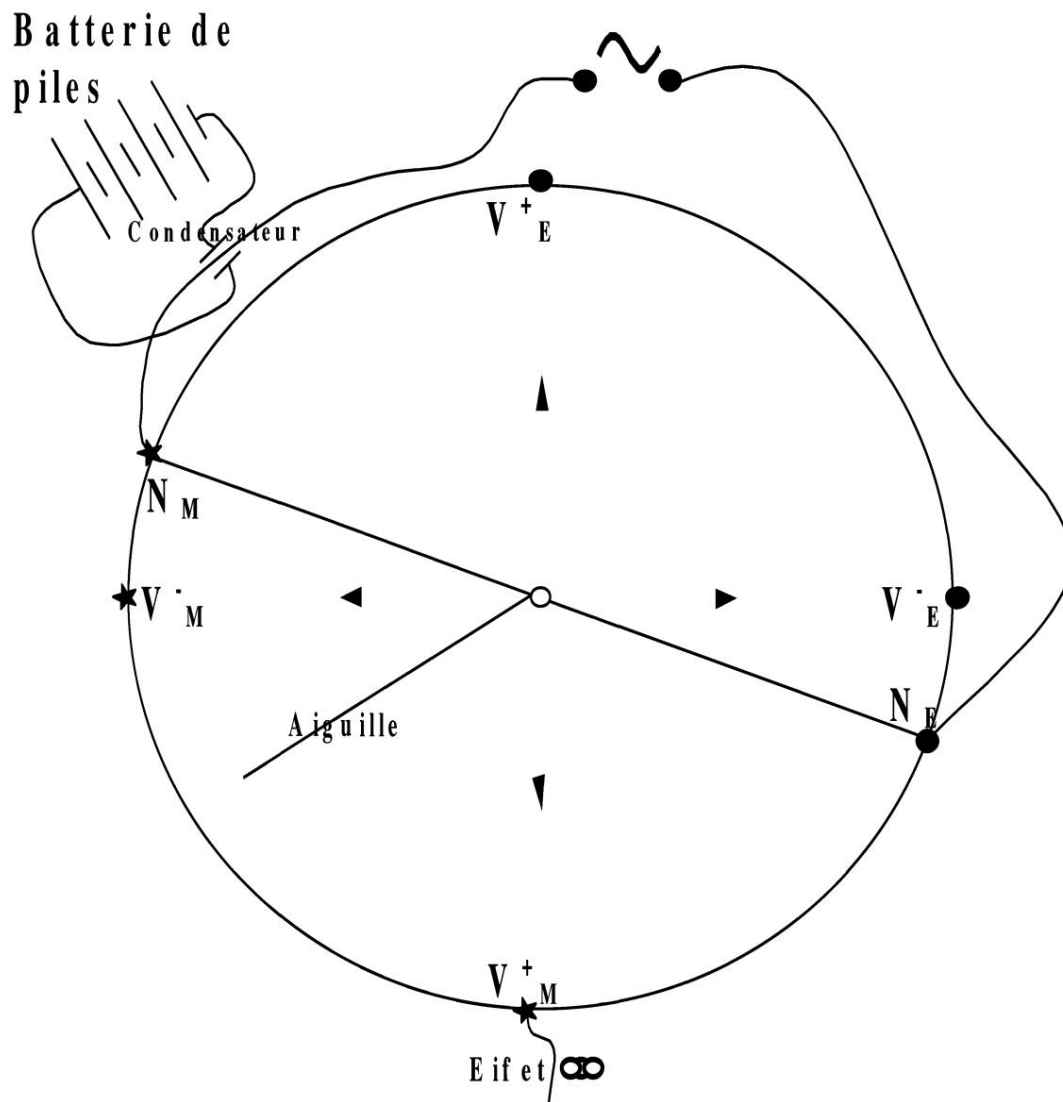

It was a continuous current since a battery was used.

It is also possible to amplify from an alternating current. The assembly is as follows:

Here the welding points are at N_M and N_E . We can choose the capacitor so that there is no short circuit. The higher the AC voltage, the greater the amplification.

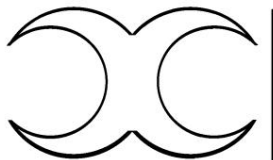

d) Another montage that makes you grow !, Amplification

Problem :

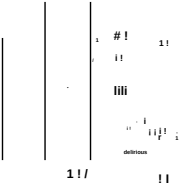

Consider the shape of the Z+ but inserted between 2 vertical lines⁴

Make a cylindrical pendulum on which it is carried on the side surface. She corresponds to an eif.

- 1) Check that this eif is undifferentiated. Detect her on the board.
- 2) It corresponds to the Hebrew word Sh M chA (Shamch'ah: listen-listen)

⁴ Discovered and named Z' by Jean de la Foÿe.

Abstract

Machine Translated by Google 3) Yes. If A, B, C are the respective vertices of the angles 80° - 40° - 60° , and Cx the half

line making an angle of 15° with CB, i.e. $(Cx, CB) = 15^\circ$. Let M be the midpoint of

CB. The perpendicular bisector at M intersects Cx at T. T is the point sought.

Exercises:

1) Detect on a plant the eifs marked on the drawing:

Note: we also have the Vital Field, and the right schin at the above.

- 2) What happens if we uproot the plant?
- 3) What happens if we add soil around the plant?
- 4) If you cut a plant at ground level, what happens?

Answers:

2) The life node disappears immediately. Z+ and Z" still detect each other and a little and slowly disappearing just like the eif of Chartres (M).

3) The node of life, at the level of the earth is not too high compared to the initial level, always detects on the ground surface. If the level is too high, it is no longer detected.

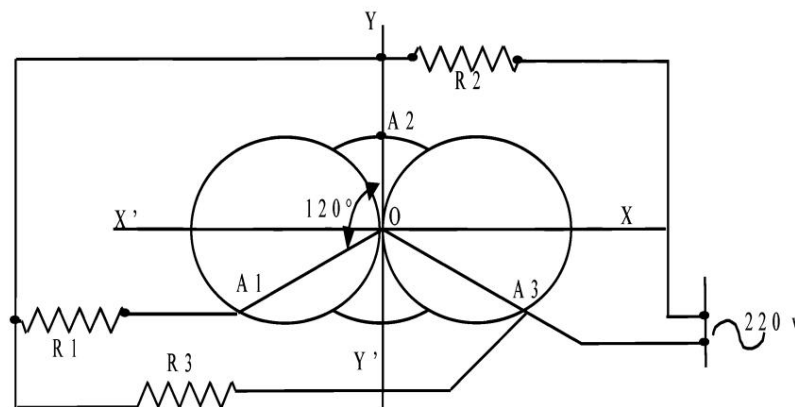

4) The life node, Z+ and Z" separate.

Exercise :

A circuit in the form of a life node is made out of copper. O is a center of symmetry. Those points A1, A2 and A3 are such that A2 is on the axis of symmetry yy' and $\angle A_1OA_2 = \angle A_2OA_3$

$= 120^\circ$. Resistors R1, R2, R3 are mounted as shown in the diagram and their values are $R_1 = R_2 = 125 \text{ k}\Omega$ and $R_3 = 100 \text{ k}\Omega$. The circuit is connected to 220 V AC.

Check that we have eifs that come out vertically from the assembly. Moreover check that these eifs are of variable "intensity" and of variable nature, this on a periodic basis.

Exercise :

We take the form opposite placed between the NF and the SF Find your eif?

Answer: It has a differentiated eif at 230° . It has in E, when it is put between 4 lines vertical, an eif at 50° .

IV. A musical instrument: the violin

Many violins respond to | K Sh Ph >. We detect the right schin above the table;

roughly vertical to the core5. If the soul is removed, the schin disappears, the | K Sh Ph > also.

On a violin we also detect a vital field.

5 Piece of wood placed between the top and the back and whose role, from a rational point of view, is to support the tensions between the top and the back.

When the instrument is played, transfer phenomena between instrumentalists can occur.
produce through the orchestra often through the conductor.

Each violin must be studied separately. One should not deduce too hasty laws on
the vital field, the eifs, the schin, the states etc...

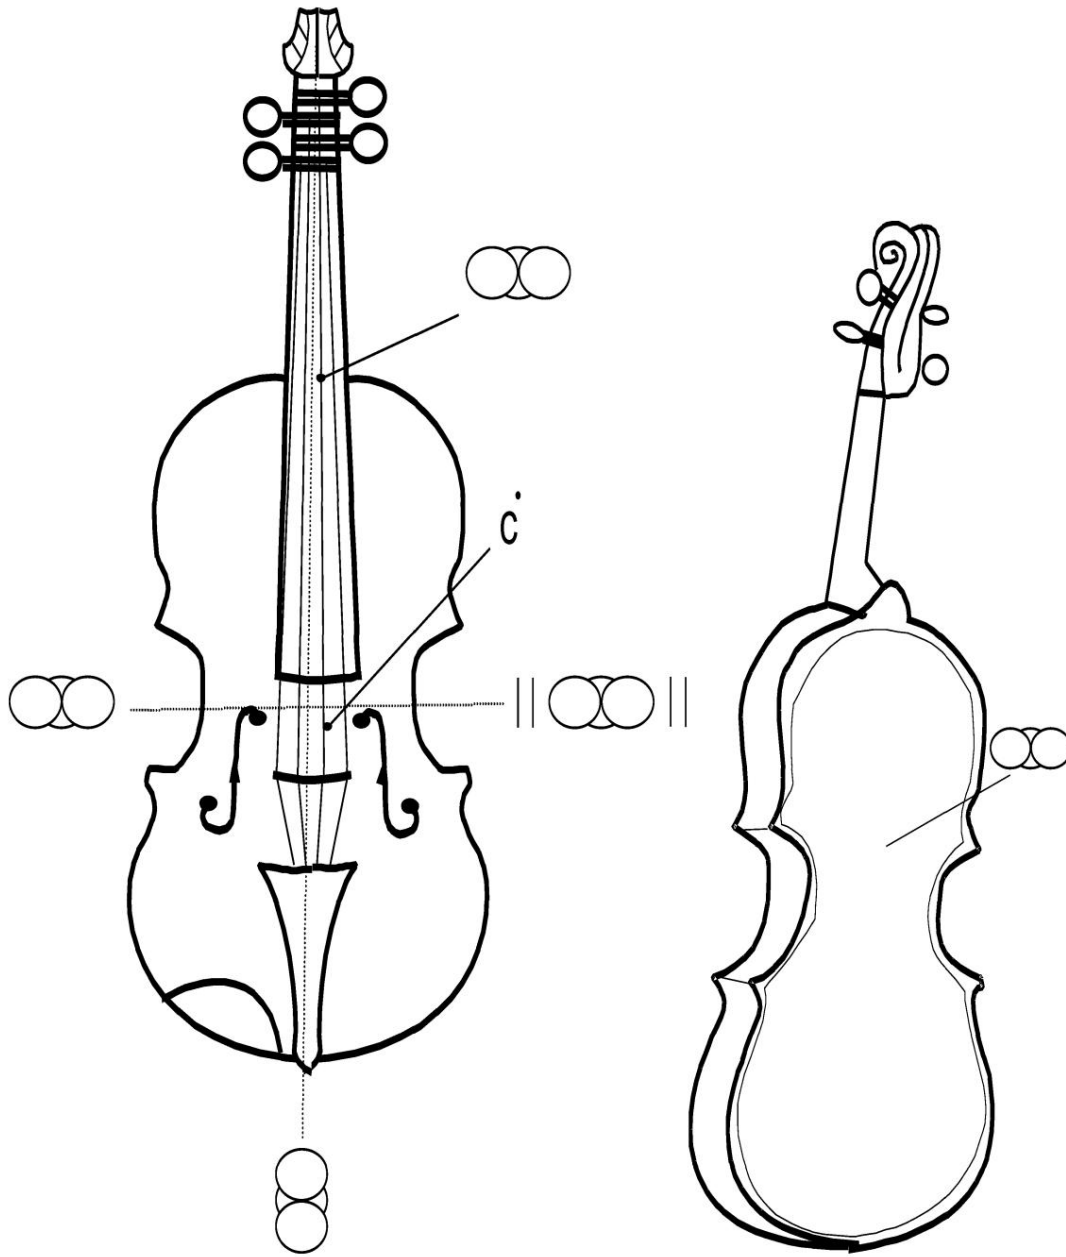

Let's say that we can find even modern musical instruments that emit at
levels other than EFF, for example what we called the Taofel fields
(C. of T.). For example, the device designed and assembled by the Bachet brothers called "Le
crystal" emits at high C. of T.. On the other hand, if we play music by J.-S. Bach on it,
it no longer emits these C. de T.. So if you want to use this device for the quality of its eifs, it
must create music for him.

We could still say a lot of things about the violin, but it calls for concepts
who are not in this course.

But, violin making, through the study of eifs, states, is presented in a completely new light⁶.

Note that a viola d'amore with an angel's head sculpted after the pegs emits the
knot of life through the mouth of the angel. We find twice the knot of life on this instrument of
14 strings of which 7 resonate by sympathy and 7 are played.

⁶ This development on the violin has been taken, with the authorization of the author, from the work of Vladimir Rosgnilk
"The Emergence of Enel or the Immergence of Landmarks - Introduction to the Study of the Forms and Fields of
Choerence" (Volume 2)

With vital field, right schin pointed in the middle, it is also necessary to add the harmonics of this form. We will see shortly the concept of form harmonic.

A. Shape harmonics¹

An important notion is that of the “harmonics” of forms. Before approaching it, let's see immediately some additions relating to prehistoric objects.

Consider the statuette known as “The Venus of Lespugue”. Many such figurines to feminine look were called Venus, which is rather pejorative because it is usually accepted by the RBB that the men of prehistory were more boeotians than human beings humans. Let's see one of these.

Lespugue is a small town in the department of Haute-Garonne, France. The region is hilly and harmoniously composed of crops, meadows and woods. Only one harshness is found in the landscape: the notch dug by the Sava, a small river with waters born on the nearby plateau of Lannemezan and which will flow into the Garonne.

Lespugue was made famous by a statuette discovered in 1922 by a prehistorian, the Count Saint-Perier. It is mainly thanks to his wife that the discovery could be made. In indeed, she sank into the cave in which her husband, herself and helpers were digging and she noticed a mound covered with grass. She took a cursory sounding there and found that the very hard ground in this place had not been disturbed like all the rest of the cave.

Following his remark, the workers begin to cut the topsoil, which has a 25 centimeters thick. Below appears a layer of hearth ash, in which we find some flints. A rock is embedded in it; the workers free it. Mon from them, suddenly, brings back an object which is at the tip of his pickaxe. He is immediately examined ; it is a prehistoric female statuette, from the Aurignacian period in ivory, comparable to the Venus found at Brassemponty, in the Landes. The pickaxe has broken the object in two pieces; the left arm is missing as a result of an old fracture. The object is so fragile that light scales stand out from its surface. This statue will remain incomplete, but no matter, the symmetry of the shapes is so remarkable that it is easy to make one perfect reconstruction. Mr. Boule, paleontologist, with whom R. de Saint-Périer is very close, is enthusiasm.

The statuette is small: 147 millimeters high by 60 wide. She is carved in a fragment of ivory from a mammoth tusk and the artist succeeded, despite the extreme hardness of the material, a work that denotes both an admirable sense of sculpture and unparalleled technical skill.

¹ This text appeared for the first time in Vladimir Rosgnilk's book “The Emergence of Enel or the Immergence of Benchmarks”. It is reproduced here with the permission of the author.

The head is small, ovoid. No facial features are marked (we can assume that the nose and the mouth were represented by colored lines). The hair, indicated by notches parallel, extends backwards, to the spine of the scapula and covers in front almost everything the face. The thorax is flat, but the breasts, attached very low, swell and move apart gradually until they form enormous skins, resting on the belly, itself framed by prominent hips. The legs are short, the feet barely outlined.

HP Eydoux remarks: "A singular garment, made up of narrow and resembling a kind of loincloth, covers the back of the legs".

He adds: "seen from the front, the statuette is made of a superposition of spherical masses assembled with a keen sense of rhythm and balance, according to a refined game of volumes and of diagrams. The anatomical reality is deliberately distorted in favor of a true abstraction ».

Eydoux asks himself the question of why such a shape; he finds no explanation but feel that it is necessary to think outside the box to be able to understand the motivations of men prehistoric. He asks himself: "Was prehistoric art art for art's sake? Certainly he could constitute a simple game, born from the forced leisure of long cold periods, during which the man decorated the walls of his shelters as well as his everyday objects. But no doubt also that religious concerns or magical rites have not, to a large extent, inspired his works".

Why is the Venus of Lespugue said to be of opulent forms? For the sake of realism say some. But then, in this case, wouldn't the artist have represented the features of the face and indicated arms and legs in a less schematic way? It is very voluntarily that the sculptor has given to the breasts, stomach, hips a disproportionate and unreal importance, while not giving the other parts of the body only an almost schematic value. He highlighted with systematic complacency the attributes of femininity". He ends his article thus: "It is difficult not to see there a work that symbolizes motherhood, fertility. Venus de Lespugue is the ancestor of the mother goddesses; it exalts procreation".

This last point had been pointed out many times by paleontologists, the magical character much less. The two points of view can also be associated. The character magic has nevertheless been foreseen by prehistorians. Chaumery and Bélizal who worked in the field of eifs from 1930-1935 have, in their work, pointed out the importance of the arrows drawn on the profiles of animals painted in the caves. We finds in this book this: "Bold explorers, like Norbert Casteret, have

discovered roughly sculpted in the caves of the Pyrenean basement the proofs of this magic that allowed hunters in prehistoric times to first paralyze game so that you can capture it more easily. To achieve this goal, they drew on the walls of their underground dwellings the shape of the coveted and previously spotted animal one of the preceding hunts², then a stylized hand usually placed on the side of the beast, marked the will, the power of man over his victim" and Chaumery and Bélizal report what Casteret writes on this subject "The Aurignacians and the Magdalenians, essentially hunters, sought to promote the success of their hunts by making them precede ceremonies whose significance appears to us better and better as we go along. as prehistoric discoveries are made. They represented the animals they wanted to kill, then, during the sessions of magic spells, traced wounds on these drawings, thus killing the animal in effigy, to ensure, on the day of the hunt, the capture real of the beast, previously bewitched".

"Thus are explained, continues Casteret, the holes, the arrows, axes, clubs which are seen on many drawings of animals. Sometimes the intention of the primitive hunter is even more explicit; the animal is represented falling into a trap, into a net, succumbing under a stoning. This theory seems above all indisputable when we consider the lions and bears of the Montespan cave which are riddled with blows of spears and arrows carried with precision in the vital parts and with so much violence and relentlessness that, sometimes, the statues are collapsed". Chaumery and Bélizal then speak of the "command baton" which was simply a pendulum.

This pendulum had the particularity of carrying animal drawings engraved on its walls. Usually constructed of antler or reindeer bone, the command staff was a detector perfect witness for hunting the animal.

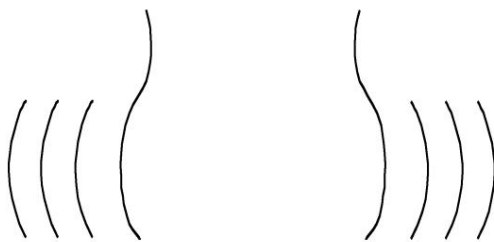

Straight or angled, pierced in its upper part with a hole which was used for the passage of a cylindrical wooden or bone rod (a rod that the man held horizontally in his hand by one of its extremities), the pendulum-stick would revolve around this support as soon as the hand of the other arm, forming an antenna, captured the reindeer radiation (if it was a matter of shooting a reindeer) and that no matter how far away the beast was.

To locate a game, the Magdalenian had only to eliminate in his brain all the drawings of animals finely engraved on the stick, to keep only that which is the subject of hunting (mental solution). »

² It should be noted that they also used duplication, which saved them unnecessary outings.

Note that there is no "reindeer", "mammoth" or other radiation. The hand, in the being human, has an intense localization character. Features are localized for mostly. But the human brain, by its fractant character, makes it possible to make a "aping" of these features and conveys them, thanks to the hand drawing of the animal; or again, one can be in contact with the enels attached to the animal-entities. This figurine called the "Venus of Lespugue" like the Venus of "Willendorf", the hips are very widely suggested. These statuettes, one might think, were used for magic ceremonies. They could even be in transfer with the female Enel.

Human beings in these prehistoric times were no doubt sensitive to notions relocated. At a woman's pelvis, the rounded shape of the hips (front view) reproduces approximately 3 times a few centimeters from the skin as in the diagram below. We will call these delocalized forms harmonics of a form which is here that of the hips. The whole body has no harmonic, it vanishes as soon as we leave the level of the hips.

The role of the so-called "Venus" statuettes in blooming hips was, thanks to magical manipulations, to amplify effects of these manipulations using the harmonics of the form and to do this, we

accentuated the width of the hips vis-à-vis the rest of the body, so as to hang up the first or even the second harmonic.

We find harmonics in the form which is the violin, this for the table of the instrument and in its widest part. The viola, the cello may have harmonics, but that's very rare. A man's body at the hips has no overtones.

Let us return to the concept of form: a painting for example: the work already ambiguous by its function is even more so when one tries to remove it from its original atmosphere, from its primitive function (what every collector does). Indeed, what was it used for and what is it for her now? But it is ambiguous when one tries to analyze it as an isolated object!

Would we succeed in fully describing this certain order that we find in a painting, we would still have no guarantee, either that this order is the primary cause of our emotion, or that we could, with the help of this order, make a beautiful painting in our turn.

But consider the ambiguity of forms. What is a circle: a moon, a sun, a flower, a head, a plate, an ellipse seen in perspective?

What is a square: a section by a plane passing through the axis of a double cone of revolution, an axial section of a cylinder, the projection of a trapezoid, some view of a parallelepiped, etc...?

A rectangle with its two diagonals is also a pyramid seen in the axis, hollow, embossed, or a railway track, and a roofing, a letter envelope. The ambiguity of any elementary form is all the greater for the fewer lines, dots, of colors (Here we fall back on the simplicity defined by Ulham). We can say that it contains then all the virtualities. In fact, it is often enough to give a name to the shape so that the ambiguity ceases. The game of raised hollow cubes stops as soon as it is decided that they are hollow or in relief. The spectator, then, projects certainty into the ambiguous form.

Let us deal immediately here with these cases of several interpretations of a given form. The eifs detected can change according to the representation that we give ourselves of the form. But then what do we detect? : ex: does the program exist before Ton gives its meaning?

E.-H. 4 is a sorting system; he creates his fields of Understanding and these interpenetrate in the fields of coherence. The eifs are from the moment there is representation, whether coherent or not.

_____ 0 _____ Consider a perspective on a plane⁵ ; it will be done by two parallels of Labatchevsky which will intersect at the vanishing point located on the horizon line. This figure in a plane can be seen a priori as a straight line intersecting with two half-lines in one point Q⁶. If we think perspective, peculiarities appear. Point Q responds to $|K Sh Ph >$ as a state. We can accentuate the answer with a $1/2$ circle (central in Q) from which rays depart, i.e. a naive representation of a setting sun. If we break through the plan in Q, the $|K Sh Ph >$ disappears; the same if we put a small point in this same Q. If we send by a wire an eif in Q, we can recover it in a point any of the angle xQy . The human being detects the eifs which are attached to his

4 p.e. to be human.

5 We find ourselves in front of what we called a Representation. _____

6 This is another representation.

representation as in the case of a house where one can choose between the house as the assembly of its parts or the house as a whole.

Maurits Cornelis Escher, born in Leewarden in 1896, in Holland, led a discreet life, all dedicated to hard work in the arduous discipline of drawing and graphic arts.

The graphic techniques he practices are classic: wood engraving with a penknife, lithography, etching on linoleum. His skill is noticeable in the engraving in several irreproachably repeated colors, which generally is only within the reach of engravers professionals. The great event in Escher's life was the discovery of his work by the men of science. Following his participation in a congress of mathematicians in Cambridge, an important publication in the magazine "Life" was dedicated to him. He had in 1954 an exhibition in Amsterdam and another in Washington. All of Escher's thought revolves around the idea of reducing the space to the plan. Indeed, in this operation which consists in flatten the objects and nevertheless make them stand out as if they were in volume, there is number of possibilities to establish different links between one object and another from the when 11 is amputated by one dimension.

In perspective an object in a given environment, itself rendered in perspective, will not have the same eifs nor the same states as in direct vision. We can ask if there would be mathematical transformations that would make it possible to pass from B.3 to the plane which would preserve eifs and states. We do not yet have an answer to this question.

One can for example associate with the sphere pierced with holes of Chaumery-Bélizal a figure on a plane that has the same eifs. We will give the diagram in the next booklet.

About drawing using perspective, we will turn to Escher. Albert Snowflake met Escher who, in particular, described this to him about his engraving "Order and Chaos" ⁷ from 1950.

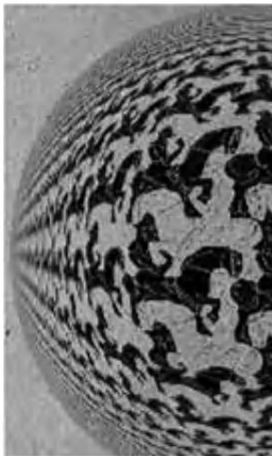

"At the center of this engraving is a partially starry dodecahedron. enclosed in a translucent sphere as a symbol of ordered beauty according to mathematical laws. In this brilliant bubble is reflected a collection of heterogeneous debris, bits of string, broken glass, broken pipe, cork, etc...

It was difficult for him to find debris that was both at the edge of the object yet recognizable and whose appearance he must still be able to render. Escher came close here frontier of the informal by approaching it from the side of the form; indeed, what can be the state of

⁷ This is reproduced in most works on the work of M.C. Escher.

destruction of a yogurt pot lid so that both this one and its
destruction ? »

In the plate "Tetrahedral Planitude", the painter has done so that we accept
the possible existence of this micro-world where the buildings are superimposed in a heap
vertiginous. Whichever way you look at this board, it is always straight. We
could also speak of the "Three Spheres", engraving from 1945.

Escher drew crystal lattices, regular fillings and
uninterrupted from the plan; we have disturbing compositions. the,
the notions of form and content disappear because they fill
one and the other these two functions successively: for example
the black riders that fill the sheet turn into
white riders on a black background when one fixes one's attention on the
emptiness that separates them. Thus the whole line drawn in the sheet
as Flocon writes, or any limit given to a form,
belong to two different figures at the same time.

A number of Escher's prints are called "metamorphoses". We see how
vague forms (shapeless forms so called by J. Ravatin) are converted into
well-defined and known forms and vice versa. A grid becomes a chessboard whose
boxes are transformed into black and white lizards, which are reduced to cells
hexagonal, which become the cells of a hive; the pattern continues with
bees emerging from these cells; these bees in their steady flight cut out words
which take the form of oncoming fish. But the black background that supports the
fish turns into a flight of birds which in turn freeze in a shapeless net
which little by little becomes a cubic network, and this cubic network becomes a city with the allure
Mediterranean. Towers of this city advance towards a chessboard; this one is transformed
again into shapeless black and white shapes to gradually become squares and
everything restart. It is interesting to note that in these descriptions there is no mention
that there are easily recognizable forms, but that the s-formless forms are neglected;
although the author recognizes them as fundamental, since Escher used them.

Escher's technique is very interesting, because it clearly expresses the emergence

Day and night

of a form based on formless forms. If we test by
example an engraving like "Day and Night", we find, if we
don't try to watch either the day part or the night part.

a state $|K Sh Ph \rangle$. This state is $|K Sh Ph \rangle$ not to express a total inconsistency but a lack of understanding.

It is the same for the engraving "La mud".

In Escher we find representations of emergence, of flight of landmarks through the passage from recognizable form to informs him.

In Escher we find a duality; it appears between pieces of the same painting. By example: in "Day and Night" A (everything relating to the day) comes out of B (everything relates to night) but B comes out of A.

Thereby (A comes out of B) to realize B

and (B comes out of A) to realize A

Two sets A and B are mentioned; they are not really drawn, and A is evoked because that we make feel B and vice versa. We are faced with a dynamic duality between A and B but for that it is necessary to place oneself in the case where one has the state $|K Sh Ph \rangle$ (which does not mean absolutely not that every time we have a dynamic duality, we will have a $|K Sh Ph \rangle$).

This one comes because we looked before A and B and then we went to the board in forgetting A and B* 10 There remains the incomprehension of what was felt before compared to what one wants to perceive next. We have the same thing in lithography

"Ascent and Descent" in which a staircase is closed; he constantly rises to the right and descends in the same way to the left.

But the other point of view is: from the drop comes the leaf. The drop encloses the depth of a flight of landmarks, as well as emergence. If we want to consider the two points of view, we will say: The leaf is the support of its emergence or the drop is supported by its extension, hence the local is the support of its emergence and the global is supported by the localization.

In reality, the dynamic duality occurs between (A comes out of B) and (B comes out of A) (Concept to be seen in the course of 2nd year).

10 We can consider that A is to B as B is to A that is to say (A,B; B,A) which has an aureolar, but this aureolar is not the dynamic duality (Concept to be seen in the course of 2nd year).

Obviously this staircase cannot be made in R^3 but on the plan, with the technique of Escher, if one considers the dynamic duality realized, the plane image can be used.

The "Belvedere", "Perpetual Movement", "Up and Down" lithographs are from same kind. On the other hand, in the lithographs "Encounter", "Reptiles" (presented at the end of booklet), 11 is rendered the concept of emergence.

researchers who find, we seek

Charles de Gaulle

B. Study on the Golden and Radiant Numbers

1. The Name d'Or

With decagons, pentagons (polygons insufficient to balance the physical field) appears the Golden number.

Egyptian constructions are based on the golden ratio.

It inverts the R and the Vi of the polarized body, which makes one think that one falls on | K Sh Ph with inverted Sh >.

To check this, you have to build it. For example, we draw the branch with positive abscissas of the curve $y = 1 + \sqrt{x}$ that we cut by the line $y = x$ which gives $x^2 - x - 1 = 0$ therefore the

positive root is $\phi = \frac{1 + \sqrt{5}}{2}$ golden number.

We will see later how ϕ inverts the polarized body, and does not touch the aura.

We will distinguish a sequence $b_1, b_2, \dots, b_n, \dots$ for (b_n) where b_n is the general term.

Consider the sequence $b_n = 1 + \sqrt[n]{7}$ with $b_1 = 1$

We can demonstrate that

Fibonacci sequence: it is such that $u_n = u_{n-1} + u_{n-2}$ with $u_1 = u_2 = 1$ i.e. 1, 1, 2, 3, 5, 8, 13,

21... It is called the Fibonacci sequence. It is obtained by the recurrence relations

$u_n = u_{n-1} + u_{n-2}$ We will call sequences of Fibonacci type those for which $u_1 > 0, u_2 > 0$ and

$u_n = u_{n-1} + u_{n-2}$.

Let's write 1, 1, 2, 3, 5, 8, 13, 21 and, below the same, shifting one row

1, 1, 2, 3, 5, 8, 13, 21

Let's make the ratios of 2 terms one below the other. We obtain :

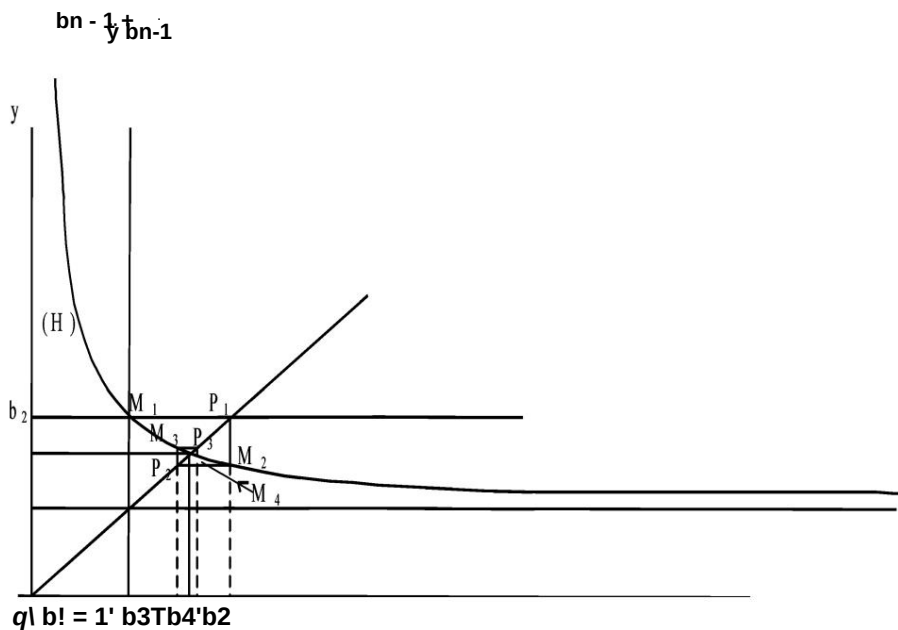

$\frac{1}{2}, \frac{2}{3}, \frac{3}{5}, \frac{5}{8}, \frac{8}{13}, \frac{13}{21}$, this sequence converges and tends to ϕ .

The Fibonacci sequence is as important, in the field of forms, as the golden ratio ϕ

The sequence of fractions which tends to ϕ can be used to construct certain forms.

We go from the sequence (u_n) to the sequence (b_n) by setting $u_n = \frac{1}{b_n}$ hence $\frac{1}{b_n} = \frac{1}{b_{n-1}} + \frac{1}{A}$

One... $1 + \frac{1}{A}$ SO

Remark : The representation graph of the function $y = 1 + \frac{1}{x}$ is, as we know, a equilateral hyperbola. At term $b_i = 1$ matches the point M_i of the curve H whose abscissa is 1

and the ordinate U_2 .

To find U_3 , we report U_2 on the abscissa leading by M_1 the parallel to Ox to point P_1 , located on the first bisector; the parallel to Oy led by P_1 , meets H at point M_2 whose the ordinate is U_3 ; to have U_4 , we report U_3 in abscissa by leading by M_2 the parallel to Ox up to the point P_2 located on the first bisector, etc... It can be seen in the figure that the vertices P of the broken line $M_1P_1M_2P_2M_3P_3...$ are located on the first bisector and are closer and closer to the point common to H and to this bisector.

Exercise: Build this figure and keep only the broken line - we will erase everything else even the H -curve

- 1) what do we detect in the center?
- 2) We pierce the center of this spiral made by a broken line. What do we detect?

Response :

- 1) | K Sh Ph with reversed Sh >

By connecting the center of the spiral by a filament to the center of a "tree trunk", we check that the polarized body rotates 180° .

- 2) This state disappears. We also check, as in 1) that the polarized body of the trunk of tree is not disturbed.

Let's go back to the Fibonacci sequence (a)

$$u_1 = u_2 = 1$$

$$u_3 = u_2 + u_1$$

$$u_4 = u_3 + u_2$$

Properties:

$$1) u_1 + u_2 + \dots + u_{2n-1} = u_{2n}$$

$$2) u_2 + u_4 + \dots + u_{2n} = u_{2n+1}$$

$$u_n = u_{n-1} + u_{n-2}$$

Reminders: Let (t_n) be any sequence: We define: $(t_n) + (t'_n) = (t_n + t'_n)$ and $a(t_n) = (at_n)$ where (t'_n) is another sequence and a any number. We thus give to the set of sequences a structure, in mathematics, called a vector space. This will be useful later.

Mathematical Considerations: We will expand on some that may be useful during the assemblies with the forms for example with what the Anglo-Saxons call "Radionic".

Consider therefore the sequences (V_n) and (W_n) such that $V_n = V_{n-1} + V_{n-2}$ and $W_n = W_{n-1} + W_{n-2}$. One does not set the values V_1, V_2 , and W_1, W_2 .

If a and p are numbers, then $a(V_n) + p(W_n) = (aV_n + pW_n)$ is a sequence of the same type, that is to say that if $Z_n = aV_n + pW_n$ the sequence (Z_n) has the property: $Z_n = Z_{n-1} + Z_{n-2}$. The proof is left to the reader.

Thus sequences such as (W_n) form a vector space. A vector space has certain dimensions. These are the ones we are going to look for. This may be useful for the study of forms.

Let us again start from (U_n) such that $U_n = U_{n-1} + U_{n-2}$. We can show that all sequences such that (U_n) can be written as a linear combination of two sequences (V_n) and (V'_n) .

Proof: Consider 2 non-proportional solutions $V = (V'_n)$ and $V'' = (V''_n)$ such

what: $V'_n = V'_{n-1} + V'_{n-2}$

$$\text{and } V''_n = V''_{n-1} + V''_{n-2}$$

Let us show that any sequence $V = (V_n)$ such that $V_n = V_{n-1} + V_{n-2}$ can be written $V = C_1 V' + C_2 V''$ where C_1 and C_2 are two numbers.

First show that if V and V'' of the type above are not proportional then

$V_1 v_2 \ddot{y}$ $V_1 v_2 \ddot{y}$ $V_2 V_i + V_2 V_3$ Suppose $\wedge T = \wedge T$ then $= y_1 y_2 + \ddot{y} = \text{etc...}$ so V and V'' are

proportional. Hence if they are not proportional then: $V_1 V_2 \wedge \ddot{y}$
 $\wedge r.$

Consider V such that $V_n = V_{n-1} + V_{n-2}$. It is perfectly determined if we know V_1 and

v_2 .

Let's look for two constants C_1 and C_2 such that: $V_1 = C_1 V_2 + C_2 V''_1$

$$V_2 = C_1 V_2 + C_2 V''_2$$

V_1 and C_2 exist and are unique because V and V'' are not proportional, i.e. the

determining : $V_1 V_1 \ddot{y}$
 $V_2 V''_2$ $\neq 0$

$$C_1 = \frac{V_1 V''_2 - V_2 V''_1}{V_1 V''_2 - V_2 V''_1} \quad C_2 = \frac{V_1 V_2 - V_2 V_1}{V_1 V''_2 - V_2 V''_1} \quad \text{et } V = C_1 V + C_2 V''$$

Hence it suffices to find 2 solutions.

Thus the vector space of sequences $V = (V_n)$ such that $V_n = V_{n-1} + V_{n-2}$ has two dimensions on the field of real numbers.

Let us seek among the basis vectors those of the form of a geometric progression of 11er term 1 and ratio q ; i.e. $1, q, q^2, \dots$

It is necessary that $q^n = q^{n-1} + q^{n-2}$ from where $q^2 = q + 1$

$a_p = -1$; here $V = (V_j) = (a_n)$

$$V' = (V''_n (\ddot{y}P) + ($$

$$\begin{array}{ll} V_1 = 1 & V''_1 = 1 \\ V_2 = a & V''_2 = p \end{array} \quad \text{so} \quad \begin{array}{ll} 1 & 1 \\ a & p \end{array} \neq 0$$

hence the sequence $(C_1 + C_2, C_1 a + C_2 p, C_1 a^2 + C_2 p^2, \dots)$

Now some values of C_1 and C_2 will give the Fibonacci sequence.

$$\begin{array}{l} C_1 + C_2 = u_1 = 1 \\ C_1 a + C_2 p = u_2 = 1 \end{array} \quad \begin{array}{l} C_1 + C_2 = 1 \\ \text{i.e. } \frac{1}{2} \left(1 + \frac{5}{2} \right)^{1/2} - \frac{1}{2} \left(1 - \frac{5}{2} \right)^{1/2} \end{array}$$

$$\frac{1 + \sqrt{5}}{2} \text{ or } \frac{1 - \sqrt{5}}{2}$$

hence $U_n = C_1 \left(\frac{1 + \sqrt{5}}{2}\right)^n + C_2 \left(\frac{1 - \sqrt{5}}{2}\right)^n$ (Binet formula)

Result :

$$a_2 = a + 1$$

$$a_3 = a(a+1) = a + 1 + a = 2a + 1$$

$$a_4 = a(2a+1) = 2a + 2 + a = 3a + 2$$

Suppose $a_k = U_k a + U_{k-1}$ where (u_k) is the Fibonacci sequence and $a_{k+1} = U_{k+1} a + U_k$

For $k = 2, 3$ this formula is true

$$a_k + a_{k+1} = (u_k + U_{k+1}) a + (u_k + 1 + U_k)$$

$$= (u_k + U_{k+1} + u_k + 1) a + (u_k + 1 + U_k)$$

what is demonstrated.

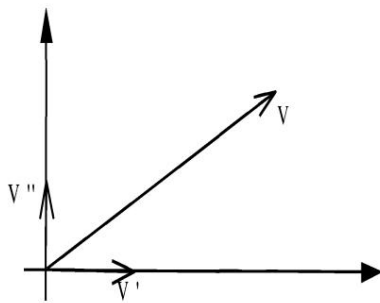

Complement :

We can take $V' = (1, 0, 1, 1, 2, \dots)$ where $V_0 = 1, V_1 = 0, V_2 = 1, V_3 = 1, V_4 = 2, \dots$

$$V = C_1 V' + C_2 V'' = (V_1, V_2, V_3, V_4, \dots)$$

$$= (C_1, C_2, C_1 + C_2, C_1 + 2C_2, 2C_1 + 3C_2, \dots) \text{ where } V_1 = V_2 + V_1$$

so $C_1 = V_1$ and C_2 are uniquely determined.

If $V' = (1, 0, 1, \dots)$ and $V'' = (0, 1, 1, \dots)$ the sequence of Fibonacci is $V = V' + V''$

Fibonacci sequence and geometry

$$AB = 1$$

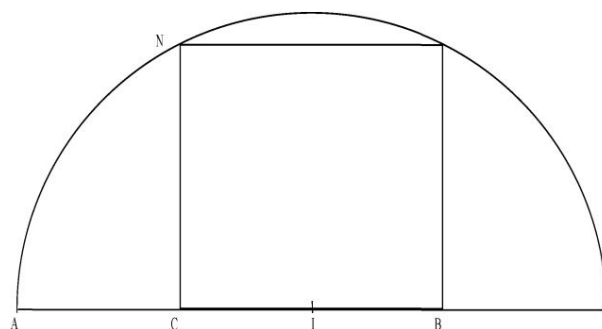

Consider a straight line which bears the points A, B, C, C' such that

$$C'B = x \quad \text{Let's share } AB$$

so that the larger of the 2 parts is the proportional mean of the smaller and of the whole segment.

¹¹ AB denotes an oriented segment

Exercise :

In this figure, we color the square in blue deep. The figure emits the Bum vertically.

Etudes de polygones :

a) the convex regular decagon:

Let C be the side and R the radius of the circumscribed circle.

$$C = 2 R \sin 18^\circ$$

$$\sin 36^\circ = 2 \sin 18^\circ \cos 18^\circ$$

$$\cos 36^\circ = 1 - 2 \sin^2 18^\circ$$

$$\sin 72^\circ = 4 \sin 18^\circ \cos 18^\circ (1 - 2 \sin^2 18^\circ)$$

Or if $72^\circ = 2 \times 36^\circ$ then 18°

$$\text{so } 1 = 4 \sin 18^\circ (1 - 2 \sin^2 18^\circ)$$

Thus $\sin 18^\circ$ is a positive root of the equation $8y^3 - 4y + 1 = 0$, so a solution

obvious is there! $y = \sin 18^\circ$ which is not $\sin 18^\circ$.

So we come back to the equation: $4y^2 + 2y - 1 = 0$

$$\text{solutions } y = \frac{-1 \pm \sqrt{5}}{4}$$

$$\text{so without } 18^\circ = \frac{1 - \sqrt{5}}{4}$$

$$\cos 36^\circ = 1 - 2 \sin^2 18^\circ$$

$$\text{So } C = 2R \frac{\sqrt{5} - 1}{4}$$

b) Length of the side of the stellated decagon (the vertices of the decagon are connected 3 by 3 convex)

$$C' = 2R \sin 54^\circ = 2R \cos 36^\circ = RC_p. \text{ Ainsi : } C = RC_p$$

c) The star pentagon

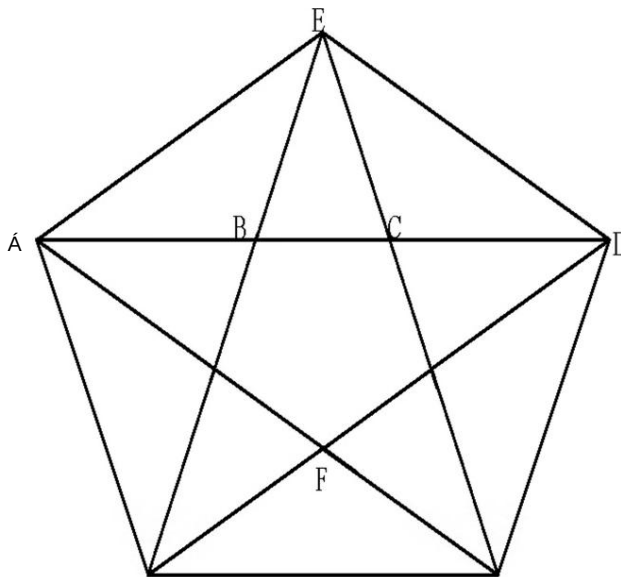

Points A, B, C, D, E, F are arranged as in the figure:

$$\angle AFD = 108^\circ, \angle ADF = 36^\circ$$

$$\frac{AD \sin 108^\circ}{AF \sin 36^\circ}$$

$$\frac{\sin 72^\circ}{\sin 36^\circ}$$

$$1 + \frac{5}{2} = 2 \cos 36^\circ = \phi$$

$$\text{Or } AF = AC \text{ d'où } \frac{AD}{AF} = \phi \text{ et}$$

C divides AD on average and extreme reason.

$$\frac{AC}{AB} = \phi; \text{ see that } AB = CD$$

$$\text{we get } \frac{AC}{AB} = \phi \Rightarrow AC = \phi \cdot AB$$

$$\text{Thereby } AB = (\phi \times BC)$$

$$AC = (\phi \times AB)$$

$$AD = (\phi \times AC)$$

$$\text{TO } \frac{AD}{AE} = \frac{AD}{AE} \sin 72^\circ = \frac{AD}{AE} \sin 72^\circ = 2 \cos 36^\circ = \phi$$

The width of the star pentagon is: $2R \sin 72^\circ = 2R \cos 18^\circ$

Note: In all form work angles are measured in degrees; others units are much less interesting.

It will happen that to numbers we will be able to associate the degree as a unit. This will bring up properties that are not obvious.

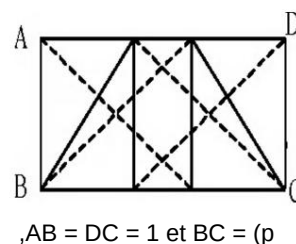

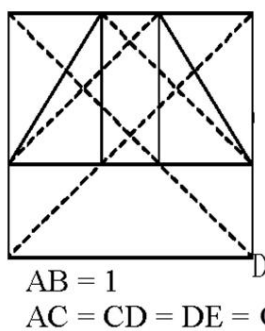

Consequences: We can consider ϕ thus where $AX = 1$ and $XB = \phi$

$$\phi^2 = \phi + 1 \quad \text{We find } AB = \phi^2 \text{ i.e. } \phi^2 = \phi + 1 \text{ so } \phi \text{ is}$$

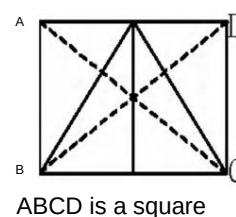

the positive root of $x^2 - x - 1 = 0$. Here we have used a

point X. This will serve to extend this construction which will give the Radiant number.

Exercise: These plots respond to K Sh Ph with reversed Sh >

Egyptian harmonic tracings (after M. Ghyka)

2) Check that in G one detects the right schin above and the 4 components of the vital field.

- 3) We remove all the holes except the one in K. Check that we still detect the right schin above.

Spiral obtained from the golden ratio C_p : it is necessary to drill holes in certain places so that interesting properties appear.

Assembly left as exercise

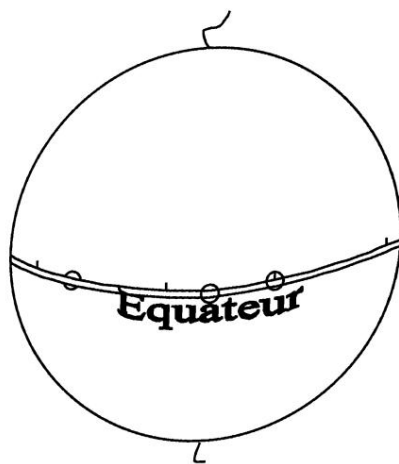

Transposition in plane of the sphere: CHAUMERY-BELIZAL

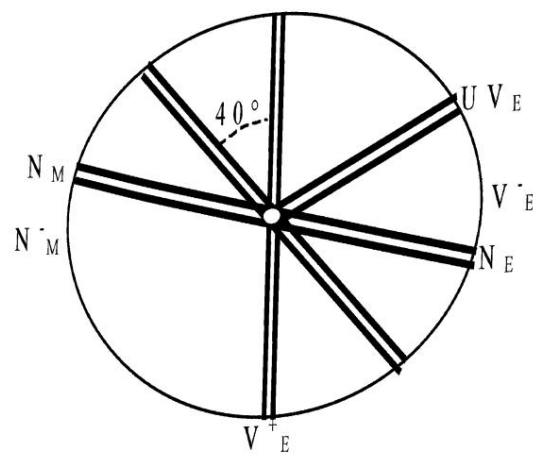

(directed by J. de la Foÿe)

By moving a cylinder over the disc, the emission on the surface is detected in the form of a vertical emission or detected at 180°. We find the spirals, geometric loci of "colors". A needle in the center emits in the extension of the V+m, the colors of the aura figured on the outside of the equator. A needle focused on the hole RV"m directed towards the center will cause the undifferentiated R to be emitted along the V+m axis in 180°.

Equatorial Pendulum "Unity"

B. Name Radiant

We took a point X on a segment AB, now let's place in two X and Y. This is what

Gérard Cordonnier in 1924 when he was in High School Mathematics class

Charlemagne in Paris. He was to enter the Polytechnic school 2 years later.

At the Ecole Polytechnique he conducted very promising experiments on clairvoyance and

mathematics and on leaving he continued research on the Radiant Number $\sqrt{j}$ — thus

he wrote it -, then on a good number of stigmatized including Thérèse Neuman, Marthe Robin, the Padre Pio etc...

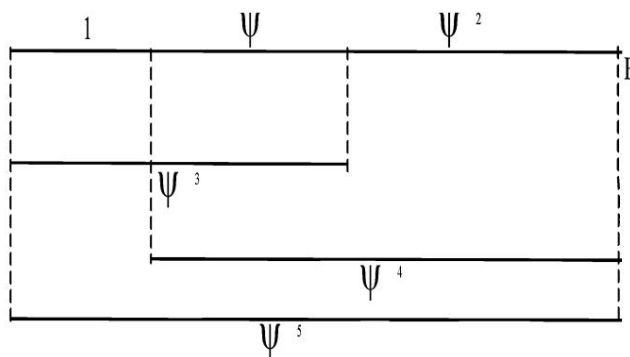

He directed the second major study on the Shroud of Turin in 1932. It should be noted that in

reward for his quality of organizer for this great congress and for his remarks

judicious, he was offered 1 cm² of the Argenteuil Tunic. This piece of fabric was placed by him between two blades with parallel faces. It issued remarkable eifs. He was used 4 times by Gérard Cordonnier and placed near dying people who were saved in short times.

His experiments on clairvoyance during sleep where he found 2 to 3 solutions to problems posed by certain professors at the Ecole Polytechnique, including Gaston Julia, showed how efficient the brain can be during sleep. He had the chance, awakening, to remember the complete solutions, which greatly astonished his comrades who were quickly convinced that no trickery slipped into these experiments.

So let's divide a segment AB into 3 segments for points x and y.

We get $\Psi^5 = 1 + \Psi + \Psi^2$ and $\Psi^4 = \Psi + \Psi^2$ which brings us back to the unique relation $\Psi^3 = 1 + \Psi$ i.e. $x^3 - x - 1 = 0$ so Ψ is the root real positive.

G. Cordonnier sought to generalize again using either 2 points

but 3 to divide the segment AB into 4 parts, i.e. the points X, Y, Z and again X, Y, Z, T, ... to generalize further. But from 3 points, X, Y, Z the process does not allow no more placing the additional segments on the same progression as that of the segments primaries. Thus the progression with the segments for obtaining the number Radiant Ψ presents the maximum of arithmetic properties on a geometric progression.

Note the formula $(\Psi - 1)\Psi/(\Psi + 1) = 1$ which expresses that 3 factors in progression arithmetic of ratio 1 have a geometric progression equal to 1.

For the number of Gold the analogous formula was with 2 terms $(f)(f - 1) = 1$.

Twice 17 years after his first discovery remained in germ, Gérard Cordonnier is invited to make a presentation at the International Congress of Symbolism at UNESCO. He exhibited there for the first time in public the extraordinary properties of the Radiant number Ψ .

Listeners are demanding a book. G. Cordonnier set to work, but on the spot to complete a draft for the use of engineers and architects, realizes that the understanding of the Radiant Number must be offered to the general public. He fully resumes his presentation by deferring all the mathematical developments in the appendix so as not to leave in the text than an initiation in images within everyone's reach.
