How I discovered uranium at the pendulum and at... 400km

HOW I BECAME A RADIESTHESIST

On June 28, 1940, being a prisoner of war in Oflag IV D,

I attend a lecture by Captain Ch. on the following subject:

RADIESTHESIA: Ancient and modern detectors.

For an hour and a half I hear stories of remarkable “detections” made with the hazel or whale rod. The explanations given by the lecturer, captain of engineers, are really unpleasant to hear for those who know the physical sciences:

“We make hazel rods because the hazel has a wavelength of 9 meters, like gold...every body emits colored radiation and an electric field..., the English shells emit violet radiation, the yellow Germans and red French... the rod works by rising under the action of the magnetic field produced by water or gold... radiation is neutralized by placing an iron object on the ground, a key for example...”.

Captain Ch., a fan of the wand, denies any power to the pendulum, considering those who use it as charlatans or hallucinators.

I leave this conference, disgusted at having wasted my time: I have the feeling that this captain is probably an excellent operator who does not understand anything about what he is doing (like an electricity technician who handles devices without know the nature of the phenomena it triggers). Moreover, it is regrettable that his conference upset a very varied audience to the point of having inspired in him for dowsing a contempt mixed with pity with regard to his followers.

It was at the door of the barracks that I made a quick decision that you cannot understand if you do not know my exact position vis-à-vis dowsing before June 28, 1940.

I had, with regard to rhabdomancy, the divinatory use of the pendulum and the other divinatory arts, the opinions professed by MM. Marcel BOLL, GUICHANT, CUNOT and other men of science who reject these practices in occultism, that is to say in this somewhat shameful world where men, unconcerned with expressing demonstrable truths, are satisfied with misleading experiments under the pretext that, from time to time, their lucubrations coincide with reality: however, an irrefutable experiment had taught me that a man, provided with a pendulum, is able, under certain conditions, to carry out discoveries strange.

Here is the fact: in the spring of 1930, General P..., of the Geographical Service of the army, told me that he had just received a visit from Colonel R... who proposed to him the creation, within this Service, of a dowsing section:

We have good n together about this project. To support his proposal, the colonel assured that, the same morning, he had observed by following on a map his son traveling from Marseilles à Algiers, its immobility for three hours in the middle of the Mediterranean. That same evening, L'Intransigeant reported that an engine failure had immobilized for three hours, on the high seas, the steamer doing the Marseilles Algiers service.

I considered this fact as sufficient to prove the existence of what the colonel called "dowsing": in fact, the experimenter had discovered, by means of a special technique, a very particular truth which he could not know. by other means. From that day on, I believed in this divinatory process, while thinking that it was reserved for special beings, probably neuropaths, but in no way considering that any man, myself for example, could achieve such exceptional feats.

You can now imagine my state of mind on leaving the conference I have just described. It is established as follows:

1. There is something real in dowsing;
2. Captain Ch.'s lecture is likely to alienate from this opinion those who have a cult of scientific truth or simply a taste for clear and objective language.

It was in order to erase this impression, which I considered likely to propagate error rather than bring closer to the truth, that I wanted to do something: a quick decision was suggested to me by the presence at my side of Commander SARRAZ-BOURNET, Director of Courses and Conferences:

Commander, please register me for a lecture on dowsing.

- So you know something about it?

- Me? Nothing: but by the time of the conference I will have documented myself”.

The announcement of my conference puts me in contact with professional dowsers and seasoned amateurs, very numerous at Oflag, but, from all the jumble of what I have been told, it is impossible to extract an idea general nor a guiding principle capable of satisfying a positive spirit. I therefore resolve to build a mathematical theory starting from the calculation of electric fields and by studying their variations in magnitude and direction due to the conductivity of the ground: I deduce the different ranges of Hertzian waves on land and sea, their absorption by trees or vertical obstacles and the weakening produced by the state of the ground according to the experiments I made at Fontainebleau. In short, I deal with the question of radiation and I lead listeners to find it quite natural that a change in terrain (fault) or a water course causes a variation in the reception of an electromagnetic device and, why not? ? a modification capable of affecting the human body itself.

The whole audience is satisfied: the professors of physical and natural sciences are happy to have heard the terms of their language used in their exact sense; those who did not know them take away the impression that the lecturer is a scientist. In short, I obtained the result I had desired: to rehabilitate, in the minds of those who are able to understand a precise language, the belief in a dowsing containing a part of truth, little known certainly but worthy of being seriously studied. When the lecture is over, the congratulations of the physicists and mathematicians are obviously very pleasing to me. But the next day! Around 8:45 a.m., immediately after the roll call, an officer came to find me:

Colonel, since you are a great dowser, please tell me where my wife is”.

Behind him I see a queue of "clients" of the same kind and I begin to regret my imprudence because I have no instrument, no method..., I have never even seen a dowser work. want to confess the truth but I think quickly that if I admit not knowing anything about dowsing:

- 1) I lose face - what I don't care about,
- 2) I destroy all the effect that I obtained with difficulty and the dowsing risks being completely “Casting” in the minds of listeners: it will become the subject of undeserved mockery. In the name of the truth, I cannot resolve myself to it.

As, on the other hand, the “customers” don't know the answer to their questions (the arrival of the letters is still a long way off) I can save time and risk a trial from which something may come out.

I take off my signet ring, hang it on a thread and look for a map of France: these operations give me time to judge the situation sanely and to prepare an experiment logically.

Here is my reasoning. Two cases are to be considered: I may or I may not know where this woman whose photograph I am entrusted with is. LET'S ADMIT THAT I CAN KNOW IT: OTHERWISE ALL EFFORT IS IN VAIN. This knowledge that will come to me will come to me all the more easily as my method of research will be simpler. What to do with a pendulum? Maybe wait for it to spin. So I'm going to walk my ring, an improvised pendulum, above a map of France with the idea that it will turn vertically to the name representing the city where the young woman whose photo my left hand has taken refuge .

After a few seconds, it seems to me that the pendulum begins to turn, more exactly to describe more or less flattened ellipses: by moving it gently, I find a point where the movement of the pendulum is circular; the center of the circle corresponds to Vannes. The die is cast. I announce to this first consultant that his wife is in Vannes and I ask the next to ask his question, which I answer with perfect assurance. I thus proclaim a fiancée in Chartres, a mother in Marseilles, a brother in Bordeaux, etc.

At the end of the day I had registered - because I wanted to check my results later - eleven cities whose names I reread with a certain anxiety which redoubled the next day, June 30, when I saw a long line of consultants coming towards me. I had nothing more to spare and I continued without the slightest shame to distribute information that

I scrupulously recorded in a notebook: date, name of the consultant, request and answer... while thinking unpleasantly of the verifications (!) which would be provided by the letters of the mothers, wives and fiancées...

Controls were obtained the same day because several officers like Colonel C. said to me at the statement of the result: “I knew it: I simply wanted to check your astonishing faculties of dowser”.

The checks followed one another quickly and quite numerous; I received them with great comfort but I must say, in all honesty, that my progress is mainly due to errors, which will not surprise any scientific mind.

Here is an interesting one: on July 1, Captain G. asks me to tell him where his wife is and shows me a photograph of a group of six people among whom he points out Mrs. G... I discover this one in Auxerre which surprised the captain, who said to me with a smile:

“I see where your mistake comes from: you have your thumb on a young girl from Auxerre”. I begin again by asking this young girl to disappear so as not to bother me any longer and above all by looking attentively at the person to be sought; I announce Mâcon” and the captain says to me: “Oh good! Thank you: she went to her cousin; it's perfect ”.

Subsequently, I avoided this error by hiding on the photo of a group the people foreign to the question.

Another mistake: I mentioned Colonel L.'s wife to Royat when she was in Bagnères-de-Bigorre; but she had spent two days in Royat with a friend before going to her final residence. This type of error was avoided by seeking the current location of the subject and not any in time.

It would take several volumes to set forth the whole series of experiments which led me to discover the exact process of the dowsing operation and, consequently, to know exactly what must be done in order to succeed.

The work that is presented to you today will dispense you with long tests of instruments and methods, subtle reflections and severe experiments which are necessary before arriving at such a simple and effective technique.

Dear reader, excuse me for delaying your first works for a moment longer: I simply want to add that This fascinating art of dowsing is within the reach of any human being endowed with a minimum of skill and Capable of a job where the method does not leave room for superstition.

When you have acquired a certain virtuosity and your pendulum has become the key to a world which still eludes you, do not keep this marvelous knowledge to yourself so that all your people may benefit from it and so as to lead a victorious struggle with us against our two enemies, the ignorant and the charlatans.

Maurice LE GALL

FIRST LESSON

DEFINITIONS OF RADIESTHESIA

1.- DEFINITIONS OF RADIESTHESIA .

All dowsers use an instrument: pendulum or rod, from which they expect a certain movement; it is when this movement occurs that they announce their discovery.

In fact, before taking the instrument in hand, they had agreed with themselves that such a movement would correspond to such a sought-after truth. This movement, expected as an unconscious movement, is a reflex on which the condition has been imposed to present itself at the moment when the truth sought is in sight: this reflex is therefore a conditioned reflex as the psychologists say.

We can give dowsing this general definition:

a means of knowledge that uses a reflex conditioned to the truth sought.

You will see that the dowsing always serves to know something which, without it, would be very difficult or even impossible to discover.

2.- CONDITIONS OF SUCCESS.

The first condition for success in dowsing is complete neutrality: the way in which the truth is obtained by the dowser is so subtle that the slightest supposition, the slightest idea concerning the solution sought comes to impose itself by preventing the true divination from occurring.

It is therefore necessary to:

imagine nothing,

Don't let anything be suggested,

Remain neutral, indifferent to the outcome.

These are three absolute obligations to which we shall have occasion to return.

3. - THE MATERIAL: THE PENDULUM.

The dowser uses the pendulum or the rod: in the first lessons, we will use only the pendulum.

A pendulum, in dowsing (as elsewhere in physics, is made up of a weight suspended by a wire from a point of attachment. The dowser holds, between the thumb and the index finger of the right hand, the wire (or the chain of the pendulum; a left-handed person usually holds it with his left hand.

We recommend a metal pendulum, suspended by a chain and finished at its lower part by a point:

As the dowser works by using a reflex movement of his hand which will be amplified by the pendulum, it is absolutely essential that he always uses the same pendulum to always be in the same conditions.

You will also see that the dowsing operations are very varied and that the operator is brought to do research with the pendulum as well seated in the calm of his office as standing outside in the open air. The need to use a unique pendulum is imperious: it is impossible to become a serious dowser, able to answer for what he discovers, by using, from time to time, a light pendulum or a heavy pendulum.

As we hope that you study the dowsing seriously and not in order to obtain some percentage of successes, we say to you firmly: take a pendulum of the average weight of approximately 40 grams which will serve you in all the cases and all your life. A pendulum of this weight must be held at the end of 5 centimeters of its chain.

The material of the pendulum does not matter: if we recommend a metal pendulum it is only so that its volume is smaller than with wood, ivory, glass, etc., aiming for the double purpose of making it less awkward on the office table and offer less wind resistance outside.

4. - PREPARATORY EXERCISES.

Sit in front of a table on which you will have placed a round box and a ruler, to the exclusion of any other object.

Take the pendulum in hand as it was said in No. 3 and present it successively above the box and the ruler. You should see and feel the pendulum swing above the box and, instead, swing parallel to the ruler above it.

If these movements do not repeat clearly, help them voluntarily so that you have clearly seen and felt the rotation or gyration above the box and the swinging or oscillation above the ruler.

When you will have obtained these two very clear movements, make the following experiment: place the pendulum above the hand or the arm of a person and obtain gyration on his hand and oscillation on his arm.

The purpose of these exercises is to familiarize you with the movements of your pendulum: you will notice that the 40 gram pendulum feels good in the hand holding it and that you can see its movements even without looking at it, which will be useful to us in operations where our gaze will be occupied with something else.

IMPORTANT NOTE. - These exercises are not dowsing: they are simply the first part of your learning, the one that allows you to get to know your tool.

From the point of view of dowsing there is no other conclusion to be drawn than this:

the pendulum turns easily on what is round and swings easily on what is long.

We will simply add that these two facts which are due solely to the characteristics of our personality are likely to hinder us during certain operations and will oblige us to take precautions so that they do not disturb the formation of the reflex which we expect.

5. - HOLDING OF THE PENDULUM.

We are now going to teach you how to hold the pendulum in the most practical way, that is to say the least tiring and the most favorable to the success of the radiesthetic operation. But first we draw your attention to two points of capital importance concerning the behavior of the pendulum:

Take the pendulum in hand only to use it and when you are ready to operate;

Before any operation and even before any exercise, make sure that you are calm, able to hold the pendulum motionless without stiffness of the hand.

Fig. 1

The hand must be flexible, the fingers holding the pendulum tight enough so that the chain does not slip:

we prefer the chain to the thread because it holds better between loose fingers; moreover it is at least as flexible as a wire and it is not, like this one, capable of presenting troublesome twists which make the pendulum pivot like a top.

The whole arm must be supple, relaxed and, unless perfectly trained, the dowser must not let the elbow rest on the table.

We give figure i our personal way of holding the pendulum and we urge all our students to adopt it.

The chain ends with a ring wide enough for the little finger to pass through: in this way the chain being held by the end cannot slip and it is useless to tighten the thumb and the index finger: the hand therefore remains flexible, relaxed and the whole arm too because you must know that it is impossible to maintain a flexible arm when the hand is forced to squeeze the fingers.

Our “pendulum behavior” was highly appreciated, even by professionals who thought they saw in it the reason for our sensitivity and our speed of operation. It is certain that it gives the operator a relaxation unknown to those who grip a thread between the fingers and that, leaving the body without nervous tension, it fully favors the arrival of the reflex: just as complete darkness favors the perception of the slightest light.

6. - THE FIRST RADIESTHESIC OPERATION.

We have created for you an easy search that you must pass on the first try and that will allow us to clearly explain the general method.

Take a sheet of paper approximately postcard size and draw on this sheet a landscape, a flower or any object. After considering this drawing carefully tear it into two halves and look carefully at the two pieces. You will hide the right half of the drawing and your first dowsing operation will consist in finding it using the pendulum.

As soon as the half drawing is hidden out of your presence, you take the left half remaining in your possession in your left hand and proceed as follows:

First time: You say to yourself while thinking about it strongly:

“I'll find where the piece of drawing I'm missing is,” and you picture that piece to yourself as naturally as possible.

Second step: Standing, you take the pendulum in your right hand and you think about the method which you are going to apply and which is simple: you think “the pendulum will turn when my left hand stretched forward is in the direction of the searched paper”.

In short, you will explore with your left hand by pivoting gently with your heels together: the gyration of the pendulum will be the reflex movement announcing that the thing sought is in sight (see paragraph 1: definition of dowsing).

Third step: You do this circular exploration, the left hand holding the left half of the drawing and stretched

in antenna” (as say the authors of dowsing works) and you wait, while swiveling gently, that the pendulum turns.

We advise you not to leave it motionless but to swing it very slightly before starting this third stage again, which is that of discovery. Here is the reason for this slight initial swing: it is simply a question of facilitating the rotation of the pendulum, because a mass, even weak, passes more easily from a movement to another movement than from immobility to a movement.

We thus benefit from two advantages: the reflex movement is faster and sharper.

Fourth time: As soon as the pendulum turns, you stop your exploration, the desired drawing is, in direction, in the extension of your left hand. This fourth stage, still just as simple, is that of the response, of the solution to the problem posed.

7. - PRACTICAL CONSIDERATIONS.

The operation described above will interest you more than you can currently imagine: you can repeat it and continue it in several ways.

For example:

- a) Standing in the middle of the room where the drawing is hidden, you will look for the direction of this paper and you will be satisfied with the answer: “That's right: that's the direction it is”.
- b) You continue searching until your hand is on the paper, object of discovery.
- c) The paper being hidden in a book of a library, you seek, with the left hand in antenna, the book where it is.
- d) This search can be done indoors or in a garden.

All variants are possible provided that the four times of the general method are respected:

ASK THE QUESTION.

CHOOSE THE PARTICULAR METHOD AND THE REFLEX.

WAIT FOR THE AGREED REFLEX. EXPRESS THE SOLUTION.

8. - THIS IS WHY WE CHOOSE THIS RESEARCH AS THE FIRST RADIESTHESIC OPERATION.

It is only to facilitate success; by way of instruction we will explain the reasons for our choice.

a) By making you make yourself a drawing of which you will be looking for half, we force you to look for something unique of which no identical copy exists in the world: we thus remove the object error which could make you find an object similar to the one you need to find.

This error of object is frequent and very trained dowsers manage to make mistakes, by finding, for example, a dog of the same breed as the one they are looking for instead of this one.

b) You can represent an object that you have created with more ease and more precision than any other: your attention is therefore attached to it without effort or relaxation and you must know from now on that without perfect attention there can be no dowsing.

c) The piece of drawing you hold in your left hand best defines the other piece you are looking for: it perfectly plays the role of witness as the dowsers say, that is to say of object defining with the most precision the one to be found.

9. - LESSONS DRAWN FROM THIS FIRST LESSON.

The success of this first dowsing research and also the errors which you will have been able to make will make you understand the first principles of this exciting art as much as useful of which we undertook the popularization.

Let's recap these all-important principles:

KEEP THE BODY FLEXIBLE, RELAXED;

OBSERVE COMPLETE NEUTRALITY, i.e. do not imagine a particular solution;

ASK THE QUESTION IN A PRECISE WAY;

WAIT CALMLY for the reflex pendulum motion to occur as you explore space to find what you seek.

SECOND LESSON

FIELD RESEARCH

10. - ON THE GROUND .

Your first search took place in your house. We will now get out of it, go to your garden or the countryside to do what is called:

A “field research”.

This operation presents two additional difficulties:

1.- a *distance* between the operator and the object sought greater than in a room and likely, in your subsequent operations, to become considerable;

2.- *natural obstacles* : these are usually found in field research.

But we will simplify these difficulties for our first outdoor tests.

11. - RESEARCH PREPARATION.

Choose an object that you know well and that you can easily distinguish when you have reached its location: a watch, a pen, a lighter, etc.

Let's say you've chosen your watch.

Go with your friend to the area where you have decided to do your tests, area without impassable obstacles where grass or uneven ground will allow you to hide the watch by placing it on the ground.

You ask your friend to hide the watch by putting it where he wants, without your knowledge of course.

12. - RESEARCH EXECUTION.

First operation: determination of the approximate place (known as: approached point) which will not be far from the place where the watch is hidden.

You place yourself at any point on the ground and search the pendulum for the direction of the watch as we taught you for the search for the torn drawing (see first lesson).

You ask the question, “I will look for where my watch is,” applying your attention to it and picturing that watch to yourself as clearly as possible.

Holding the pendulum with your right hand, you extend your left arm "antenna" agreeing that the pendulum will turn when your left hand is in the direction of the clock: do not try to imagine or guess where the clock is hidden.

You give the pendulum a slight rocking motion and gently pivot on your feet together, waiting for the pendulum to turn.

As soon as the pendulum turns, you come to a standstill: the direction indicated by your left hand, at this moment, must pass near the place where the watch is hidden.

Materialize this direction, this line, by planting - or better still, by having your help plant - a few stakes.

But you do not know near which point of the line thus determined is the object sought: to find out, you will "change station" and perform the same operation from a new point.

You thus find another direction, another line that you will also materialize by stakes: the point of intersection of these lines is the approximate location that this first operation can provide you with: it is called the approximate point. You plant a stake there.

Why do we speak of approximate point?

Quite simply because the sighting done with the hand lacks precision: the meeting point of the two lines obtained in this way cannot therefore be precise.

The maximum precision of the approached point corresponds to short sightings intersecting at right angles.

13. - SECOND OPERATION: IMPROVEMENT OF THE APPROACHED POINT.

It is possible that the watch will appear to you when you take a circular look around the approached point, for example if it has been placed in a lawn that does not entirely hide it.

But the method that we teach you allows you to discover a tiny, invisible or buried thing: you must therefore initiate yourself to find the precise point where it is hidden.

To this end, you are going to carry out a new search for the watch by placing yourself a few meters from the approached point: remove or have removed the stake which no longer serves you and start again the search for cross directions it will be easy for you to obtain in these conditions of short lines intersecting almost at right angles.

This time as the watch is not far from you, you will only look at the near terrain: the intersection of the two new lines will give you a point extremely close to the precise point, an improved approximate point.

14. - RESEARCH OF THE PRECISE POINT.

If this new point does not yet allow you to see the watch, it is necessary to carry out a slightly different operation, the one which gives the greatest precision but can only be used near the exact location of the object. look for.

You place yourself about 3 meters from the improved approach point and you have the stake that determined it removed.

You look for a new direction of the watch (always by the direction of the left hand at the time of the gyration of the pendulum): walk by advancing the right foot regularly and slowly along the line thus determined.

During this sliding step with the right foot (which the left obviously follows) you think strongly: "the pendulum will turn as soon as the tip of my right foot arrives at the exact place where the watch is".

This place is the "precise point" where you have to look carefully, scratch or dig to discover the watch (or whatever object you may have been looking for).

15. - THE FIVE OPERATIONS:

You see that it will generally take five dowsing operations to discover, on the ground, the point where there is a hidden object;

Two searches for crossed directions to obtain an intersection giving the "approached point";

Two similar searches but much shorter to obtain, always by intersection, an improved approach point;

A precise search, by progression, on an even shorter direction.

16. - FIELD RESEARCH TRAINING.

It is essential to start by carrying out blank searches, that is to say to search for an object whose exact position is known.

You place an object on the ground without hiding it in the slightest and you scrupulously carry out the operations that we have just described: this pseudo research will be extremely profitable because it will familiarize you with the technique that we have detailed and it will prove to you the validity of the following tips:

a) Think intensely about what you are looking for: you will realize that you have to think intensely even about an object that you see for the reflex to occur.

b) Walk very slowly on the line you are exploring. You will see the time the pendulum takes to turn when you pass over the object seen and you will recognize that it takes at least an equal time to start turning during a real hidden object operation.

As we have pointed out, by going too fast we risk finding the object further away than it really is (we may even find nothing at all). This error is very frequent even at the confirmed dowzers who often exceed the precise point.

A process makes it possible to eliminate this error by walking in the two opposite directions and taking the average of the two positions found: admit that it is simpler, more logical and more precise to walk slowly and find, at the first attempt, the point exact: because we are never sure to make the same mistake in both directions. On the other hand, there is always an interest in carrying out the dowsing operation so that it is as short as possible: weariness generates errors; in this case, it is the one who walks slowly who finishes his search soonest.

c) Use a pendulum of suitable weight, not too light, which one can hold short: thus, one obtains a rapid reflex, giving clear indications for the directions of the method of intersection and for the end point on the direction of the journey.

Our experience has led us to adopt a 40 gram pendulum which allows to operate quickly and does not offer a grip sensitive to the wind.

17. - THE REFLEX MOVEMENT.

You will notice, in general, that the pendulum movement in the field is much more lively than during previous searches in your office. Put up no resistance to the amplification of this movement which can cause the pendulum to turn horizontally like an airplane merry-go-round at the fair.

The blank exercise has the advantage of making you acquainted with your pendulum and also with the reflex itself, the precision of which will amaze you: you must, before undertaking the actual search operation, have obtained a rapid and regular: the rotation movement of your pendulum must be established quickly without the hesitation which results in a certain number of more or less elongated ellipses during which the operator wonders if there is really oscillation or gyration. Moreover, the gyration must, once established, be maintained regular as long as the attention of the dowser has not relaxed. As soon as the attention relaxes, the pendulum must stop turning and resume the slight oscillation which is always its state of rest, awaiting the reflex.

The rapidity of the reflex obviously depends on the operator who perfects it like all other reflexes by logical training. But this speed, essential to become a successful dowser, is also due to the mechanical qualities of the pendulum whose point of attachment must be very close to the center of gravity (in order to avoid secondary movements which slow down the change of the oscillation in gyration and reverse change). A good pendulum must therefore have the shape of a cone whose point is directed downwards.

18. - A FIRST VARIANT.

During the final walk, you can explore the line that passes over the object sought by means of a cane instead of the tip of your right foot.

Indeed, the point of the foot is only used to try, one after the other, the points of the line, to ask the question for each point and to mark the precise point by immobilizing the foot as soon as the pendulum turns.

We recommend the process of the point of the right foot because the attention of the dowser is better in this way of operating: the operator automatically takes a slow and slippery walk which is essentially conducive to the awareness constituting the third time of the process. 'operation:

Wait for the reflex (review § 7).

19. SECOND ALTERNATIVE.

In the case where one operates in an open area, there is a process as fast as it is elegant which we believe useful to point out to you.

We seek the direction of the object to discover (as it is said in § 12) and when we have found it with the left hand

Fig. 3

outstretched, one slowly lowers this left hand so as to explore the ground in this direction, from the distance to one's feet.

The convention to set is then the following:

When my hand indicates the point on the ground where the object sought is, the pendulum will turn.

This process allows, from a single station, to obtain an interesting approximation and to better choose the location where you will go to perform the second operation of § 13: improvement of the approached point; under these conditions, you save time and, knowing very quickly the approximate position of the object sought, you can position yourself so that your sights in crossed directions give a very clear intersection, almost at right angles.

It may even happen that by walking towards the point that your hand has indicated you can discover what you are looking for; to do this, you have to look carefully at the ground at the place that this second variant has made you locate and try to clearly define this place to walk towards it or choose the station to the right or left of its direction which will allow good aiming. 'intersection.

However, this interesting way of proceeding is not always applicable because it requires clear ground with good visibility; this is why we have explained to you, in paragraphs 10 to 13, a general method which, in any case, can be applied successfully.

THIRD LESSON

THE SEARCH FOR WATER:

THE ART OF THE DOWSER

20. - PREPARATORY EXERCISE.

Expect to get much sharper and faster pendulum movements in the field when searching for water than you got in previous searches.

This change is due to two causes: a special sensitivity of your body and the great facility with which you think: "I'm looking for water: is there water there? ". This question is obviously the easiest to ask.

You can verify what we have just said by the following experiment which we call "blank" research.

Position yourself a few meters from a stream, stream, river, etc. that you can cross (either by stepping over it if it is a fairly narrow stream, or on a footbridge or a bridge in the opposite case).

Hold your pendulum swinging it slightly and walk slowly towards the water thinking intently, "The pendulum will turn when I am above the water".

You will then see the pendulum turn very quickly: do not bother it, on the contrary: get used to feeling your pendulum turn as if an engine was driving it.

Continue your walk and as soon as you have passed the water your pendulum will stop turning and will resume its slight swing which is its position of rest or of waiting.

Repeat this exercise several times and tell yourself - which will become true - that you will obtain, on the invisible underground water, the same vigorous reflex as on the visible water that you have just crossed.

You will then be ready to study our third lesson which will make you a good seeker of water, an excellent "dowsers".

21. - THE ART OF THE DOWSER: SEARCHING FOR UNDERGROUND WATER.

We are going to teach you how to discover underground water: streams, aquifers, springs, etc.

The dowsing makes it easy to discover the water in the basement as well as all the information necessary for its use: we therefore seek the location of the underground water, its depth, its flow, the direction of the current, the kind of water.

22. - SEARCH FOR THE LOCATION.

First case: it is a question of searching for water in the basement of a small plot (less than 100 meters on a side for example).

Walk in a straight line crossing the field from end to end, the pendulum being slightly swung by the right hand. While walking slowly, think: "the pendulum will turn when I

find on the site of an underground watercourse”. As soon as the pendulum turns, stop and mark on the ground with a stake or simply by making a sign on the ground with your right foot.

Then continue your walk in a straight line because there are probably other water points to discover.

Then, you traverse new lines and thus obtain, on each of your routes, a certain number of points under which there is water and where you can refine the search by operating as we teach further on.

Second case: it is a large piece of land where such walks would be impossible or extremely long.

Place yourself at any point on the edge of the field and search, using the pendulum, for the direction in which the underground water is (as you did for the watch: second lesson, § 12). This direction, indicated by the left hand in antenna, being materialized by stakes or located on the ground, you will seek another one by the same method: the intersection of these two directions will give you the place where you will be able to operate as in the previous case of a small plot.

Note that you apply the general method of “FIELD RESEARCH” for groundwater; however, in the search for water, it is not necessary to stake the directions with the same precision as in the search for a small object.

Groundwater limits

It is not enough to know a few points under which there is an underground stream.

You will therefore seek the limits of this watercourse, its banks as the dowzers say: this is very easy. Stand at one of the points you have marked and think strongly, “The pendulum will swing as long as I am above groundwater”. Instantly your pendulum will swing: walk slowly, right foot forward and stop as soon as the gyration stops: by doing this short exploration in several directions starting from the water points that you will have marked, you can trace on the ground the two banks of the water: the underground water course then finds drawn exactly: you have the exact location, with its real width.

Important note. - If you operate correctly by asking the question well as we teach you, all the water points that you have marked on the ground will be united by the lines which draw the “banks”: it may be that these lines are complicated, that there are several underground currents, a confluence of two currents...: the method exposed above allows you to draw on the ground the plane of the underground water so complicated that it can present itself in the land you are exploring.

23. - MEASUREMENT OF THE DEPTH OF UNDERGROUND WATER.

You will, in fact, measure the depth of the water.

Stand where you want to know the depth of the water: take the pendulum in your hand (slightly swung) and think: “The pendulum will turn when I say the number that measures the depth of the water that is under my feet”.

You count slowly: 1 meter, 2 meters, 3 meters... If the pendulum turns when you say 12 meters, the depth of the water is approximately 12 meters.

To obtain more precision, start counting again by saying: 11 m. 50.11m. 75.12m. 25.12m. 50. You will thus have the depth at 0 m. 25 near, which is the maximum possible precision for the level to be measured.

Remark. Since nothing, in general, is known about the depth of water, it is convenient to start like this:

Is between 0 m. and 10 m?

Between 10m. and 20 m?

Between 20m. and 30 m?

If the pendulum turns when you announce: between 20 and 30, you only have to specify by restarting the measure of

20 to 30; count 20, 21, 22, 23, etc.

24. - FLOW MEASUREMENT.

Same method as for the depth: just think: "The pendulum will turn when I say the number that measures the flow of the underground stream that is under my feet".

We advise counting as follows:

Is it between 0 and 100 liters per hour, between 100 and 200, etc.? If you don't get the expected reflex before 1,000 liters, continue counting in cubic meters: between 1 and 10, between 10 and 20, etc.

Very important note. - Many dowsers make errors on the debit because they don't know exactly what they are looking for.

A body of water can be animated by a very weak current or even be almost motionless: what interests you is not the volume of water which passes under your feet but the quantity of water which one can there pump without the level dropping noticeably.

This is what you should take as the definition of throughput in your research.

Example: our search for water at the Golf de Fontainebleau. After having operated as we teach you, we found 60 cubic meters of water per hour of flow at a depth of 12 m. 50. At this depth, a pump exhausting 20 m³ per hour did not lower the level, another removing 50 m³ no more.

25. - SEARCHING FOR THE DIRECTION IN WHICH THE UNDERGROUND RIVER RUNS.

When you have traced the underground watercourse on the ground as it was said in § 22, you place yourself in the middle of the watercourse and take the pendulum in your hand.

Think that you are on the water and that your pendulum must turn: when it turns, walk very regularly following the course of the water traced on the ground: after a few meters turn around and retrace your steps towards the point of departure.

You will have noticed that, in one of the two directions of the course, your pendulum turned much more easily than in the other where it tended to stop. It is by going up the current that the pendulum turns the fastest:

This is easily understood because it is by going against the current that you cross the most water for the same speed of progression.

This method, which is easy and safe to use, familiarizes the apprentice dowser with the most violent sensations obtained by the exercise of dowsing: it makes him aware of his sensitivity and makes his sympathetic nervous system more suitable for the production of pendulum reflex.

26. - SEARCH FOR THE LOCATION OF A WELL.

When you have obtained the groundwater route, the depth and the flow, you can provide useful information to anyone who wants to drill a well in this region.

It may happen that several points are equivalent from the point of view of the subsequent yield of the well which would be drilled there, but that, for reasons of ease and cost of the work, one of them is more advantageous.

The dowsing still allows you to choose the best point: it is enough that you place yourself successively on the points between which one can hesitate and that you strongly think: "My pendulum will turn on the point where the well would be most advantageous".

27. - THE NATURE OF WATER.

In many cases, the search for water is not the search for just any water; you may be asked for drinking water, mineral water similar to that of a known spa, special water for industrial needs, etc.

Dowsing allows you to find only what you need to look for: if you want to find drinking water, you just have to think only about drinking water by saying:

"My pendulum will turn when I stand on a stream of clean water." If you think this convention perfectly, your pendulum will not be able to turn on polluted water.

Similarly, if you want to find water with the same composition as Vittel water, think "My pendulum will turn when I stand on water analogous to Vittel water".

Use of cookie

If it is absolutely useless to hold a bottle of water or a wet cotton... in the left hand when you are looking for water of any kind (water for irrigation for example), it is good to hold , in your left hand, a sample of the special water you want to find: but don't forget that this "use of the witness" does not at all exempt you from applying your thoughts to what you are looking for.

Check it yourself when you will be a good dowser by doing your research with anything in your left hand: you will see that the thought of the dowser always leads the search: if this thought has a failure, the dowser finds something else only what he was looking for or finds nothing...

28. - PRACTICAL CONSIDERATION.

Do your research for water without taking into account what the examination of the ground could suggest to you.

The underground stream is not necessarily at the lowest point... at the place where the grass is thickest... at the coolest place...

We have seen wells on heights, springs in the pebbles, thick grass contented with an insignificant infiltration retained by a layer of clay.

In the search for water as in any radiesthesic operation, one must be wary of suggestions: the radiesthesist must tell himself that he has a technique capable of discovering truths that escape any normal observation, even of a specialist, and he has nothing to gain by listening to the opinions of a geologist concerning underground research, of a hydrographic engineer for a dowsing operation.

Far be it from us to depreciate the knowledge of the specialists: we simply say that if they know what is asked of the dowsers it will be useless to have recourse to the latter. If they do not know him, they must know that the dowser does not work, like them, by observation and deduction and, consequently, they must let him operate with his own technique.

About this practical consideration, we can assure that if the dowsing were universally known, that is to say if the general public knew its nature, the general technique and the conditions of success, the dowsers would commonly have success. many more. Until this happens, we strongly advise all operators, beginners or not, not to accept any comments or suggestions regarding the problem they are presented with. We must immediately stop the flow of words that often accompanies the question asked: "I have the idea that you should look there. It seems to me that there is a source... one of your colleagues has already found... ", etc.

A dowsing exercise at home.

It is relatively easy to discover a body of water or an underground current: on the other hand, the search for the flow presents, for many beginners, great difficulties.

Here is an exercise as easy as amusing which can be repeated very often and constitute a remarkable method of training and verification of This training.

This involves measuring the flow of a water pipe in your house or apartment: note that this problem is more limited than that of finding any underground current: at home you know within what limits the flow is necessarily found and you choose, as a unit, a liter per hour, which you can easily imagine.

Here is how to operate: stand near the meter or near a point in the pipeline and, while the tap is running (opened by an assistant) count the number of liters per hour of flow by the usual convention: the pendulum will turn when the number pronounced is that which measures the flow rate of the tap.

The control is very easy since it is enough to fill a liter by counting the necessary time.

The exercise can be repeated by varying the speed at which the liter is filled from the closing of the tap to its maximum opening.

Note that, for this exercise, you can even do without help by opening the tap yourself and checking the flow after having found it on the pendulum.

However, we recommend operating in the total unknown with a helper who may not even open the tap at all, creating a zero flow that you will have to find equal to 0. We very well see a competition being established between friends, beginner dowsers, who would like to practice measurements using the pendulum or the rod.

The Seeker and the Chatelain

One of our friends, a skilled baguettist, was invited one day to a chateau: after an excellent meal, the master of the house asked the dowser if he could locate the water pipe supplying the various buildings in his park.

Our friend, confident in his mastery, took his wand and set about beginning his research; after a pleasant walk in the gardens, he defined certain crossing points for the water current and, under the amused gaze of the squire's whole family, he drew a rather complicated itinerary in the lawns, paths and beds.

"There you are," he said to the master of the house.

- Very well, answered this one: the course is exact. So you have detected the underground water current.

- Perfectly.

- Can you measure the current flow? I was told that this was commonly done". Our friend confirmed this possibility and announced a flow of 800 liters per hour.

Everyone smiled and the squire explained the general hilarity:

"Bravo! You have found the flow rate of my electric pump: but there is no water current since I gave the order to cut off the electric current".

Our friend who is an engineer, laboratory director, was a little offended but he reflected; he understood that his discovery applied to a current of water which had existed but no longer existed, therefore that his work had applied to the past: he had announced present what had passed. He deduced that this error proved that the dowsing search could be done voluntarily in the past since his thought had done it involuntarily: he swore that he would not be caught there anymore, that henceforth he would put his question to the present and he proposed:

"I will tell you exactly what time you had the power cut off".

Positioning himself in the path of the water current, he went back in time, counting by quarters of an hour and minutes and announced: "The water has been stopped since 1.47 p.m.". It was correct.

Morality.

The story above is not a fable but it does have a moral nonetheless.

When looking for what is happening at the time of your research, add "now" to your question.

Is there a stream of water here now? You will thus avoid confusing a news reporter with a... historian.

FOURTH LESSON

THE BAGUETTE

29. - DEFINITION.

Everyone knows the wand of the dowser formed by two elastic branches whose two extremities are securely tied, the other two being held firmly in each of the two hands.

The old dowsers used a hazel stick (or hazel) cut to form a fork with two branches of equal length: the hazel was chosen because this wood is very elastic and breaks less easily than others.

Currently, various materials are used for the manufacture of rods: ebonite, steel, baleen, etc... Without a doubt, the best rods are made of this kind of elastic horn that is removed from the baleen of the whale. and which is commonly referred to as a whale.

We therefore recommend, in an exclusive way, the genuine whalebone stick, made up of two identical strands, tied together over a few centimeters in length at one of their ends. Thus constituted with elements of chosen quality and well matched, the rod gives complete satisfaction and does not present any fragility.

30. - PRINCIPLE OF THE USE OF THE STICK IN RADIESTHESIA.

The rod, in the hands of the dowser, behaves exactly like a spring: this is why it always includes elastic branches.

You know (see § 6, first lesson) that the dowsing discovery is accompanied by a reflex movement that the dowser has defined in advance: when the pendulum is used, the reflex movement is the transformation of oscillation into gyration. When the dowser uses the wand, he agrees with himself that the wand, kept in balance, will jump by breaking this balance at the precise moment when he will find what he is looking for: now, everyone knows that there are two balances possible, the stable equilibrium - which re-establishes itself after a disturbance - and the unstable equilibrium which is broken by the slightest disturbance without being able to re-establish itself.

It is therefore the unstable balance that must be chosen as a waiting position before the reflex that will cause the stick to jump. The whole art of the baguette, the whole secret of the wand (if there is a secret) therefore consists in holding the wand in an unstable equilibrium: let's learn to hold a wand.

31. - WAND HOLDING.

There are several ways of holding the wand during a dowsing operation: all these ways have this in common that they constitute an unstable balance by opposing the action of the dowser, making an effort to bend the branches of the wand, to the reaction of the rod operating like a spring.

We will only show you the classic outfit which, in our opinion, is not inferior to the others: some authors call this way of holding the baguette the "French method": you will recognize that it is simple, easy and self-explanatory. very clearly.

Hold the branches of the wand, one in each hand:

palms facing up, each branch passing through the thumb, index and ring finger intervals as shown in Figure 4.

Hold the wand in a horizontal position by varying the efforts of your two hands: you can, in fact, squeeze the branches more or less tightly in your hands, spread your hands more or less apart, twist more or less minus the branches by rotating your wrists inward or outward.

By seeking balance without tightly clenching your hands, you will get an unstable balance. It is easy to check if the balance obtained is unstable: in this case, in fact, it is destroyed at the slightest pressure exerted by a third party on the tip of the stick, which then jumps up or down. .

In general, a few minutes are enough to manage to hold a rod correctly and to become ready to use it for the dowsing discovery: in any case, it is completely useless to attempt the slightest operation if the unstable balance that we have just describe was not obtained.

32. - EXPLANATION OF THE MOVEMENT OF THE STICK.

When the balance is broken at the moment of the reflex announcing the discovery, the stick jumps (up or down) without the operator being able to hold it: much better: the more he wants to hold it the more it escapes him.

This is easily explained although no operator seems to have suspected the truth. In fact, the alleged mystery lies in the unusual position of the hands which distorts the customary manual reflexes. When the equilibrium is broken, the operator who thinks he is holding the stick is in fact doing everything he can to make it jump more energetically.

Moreover, all the baguettetists know that the wand jumps with a force which depends on the effort put into play to hold it and on the action of the dowser, which is obviously equal to the reaction of the wand.

33. - HARD STICKS AND SOFT STICKS.

Rods with fine and light branches are held in unstable balance by means of a very weak action since their reaction cannot be strong: at the moment of the break in balance, this weak action will cause the rod to jump without great energy. On the contrary, with thick branches requiring a powerful action, the jump of the rod takes place with a brutality which can be dangerous for the face of the dowser.

There are therefore two kinds of sticks: hard and soft depending on whether the branches are strong or thin.

Which should you choose?

The answer to this question is very clear: at the beginning of training, when it is a question of acquiring powerful reflexes and of measuring very sensitive efforts in order to create an unstable balance, the hard stick is essential. Later, when the operator is absolutely in control of his actions, even extremely weak ones, when he is sensitive to the most tenuous reflex, it will be in his interest to use a soft rod, requiring only a tiny effort and leaving him more free. to think of the operation itself, of which the appearance of the reflex is only the simple and rapid conclusion.

34. - COMPARISON OF THE PENDULUM AND THE STICK.

You see by what precedes that the use of the rod requires a more complicated technique than that of the pendulum: the rod requires an apprenticeship whose importance should not be exaggerated but which cannot be eliminated.

On the other hand, the use of the wand immobilizes both hands instead of just one for the pendulist.

Opposite these points favorable to the pendulum, it should be noted that the reflexes of the rod are clearer, more instantaneous than those of the pendulum, which constitutes a precious advantage from the point of view of the precision of the results when the operator must to move. Finally, the brutality of the reflex of the wand, against which the dowser cannot defend himself, forces him to become aware of it in all its fullness, so that the pendulist who exercises with the wand, improves, in enormous proportions , its pendulum efficiency.

For the pendulist, the research with the rod on the ground is a revelation: he knows a Quickness of which he had no idea and, then, taking up his pendulum, he will be astonished to preserve, more or less, the sharpness and the instantaneity due to the wand.

Let us add that it is absolutely false that the man needs a special sensitivity to make a success of the radiesthetic researches with the rod: the reflex only is a little different. You just need to know how to hold a wand. But it is essential.

On the other hand, it should be well known that the rod, like the pendulum, is only inert matter and that the dowsing discovery is not the fact of copper or a piece of whale, but of a whole man. entire.

In summary, we can say that the study of the rod is essential to the dowser, even if he intends to operate, thereafter, with the pendulum exclusively.

On the other hand, as we will see later, the dowser who wants to devote himself solely to medical dowsing by working on the patient himself, has an interest in using the wand.

35. - RESEARCH TRAINING BY MEANS OF THE STICK.

When you know how to hold the wand, you can begin your training.

You will first do a trial run, that is to say you will seek to obtain the reflex of the stick which jumps at the moment of discovery: it is a question of familiarizing yourself with your new tool before attempting it. actual dowsing search operation.

Here is how you should do this test: place a coin on the floor (or outside, on the floor), hold your wand as prescribed in § 31 and walk very slowly towards the room agreeing: when my right foot will be on the coin, my wand will jump.

Repeat this test several times with the coin and with other objects placed on the ground in this way.

These tests will allow you to very quickly improve the grip of your baguette and to fully understand the technical part of the profession of baguette which, we repeat, is quite delicate. If, as we advise you, you have a hard stick and a soft stick, you must, from these first tests, make the comparison.

It is absolutely necessary to know his wands, the best position of hands and the suitable twist of the branches before starting a real dowsing search in which the wand will jump when you pass over the object sought but invisible.

It is for lack of having carried out this preparatory training that operators have abandoned the wand, believing that they lacked the necessary gift (!), thus depriving themselves of great joys and of an extraordinarily effective means of improvement.

Let us add, to finish with the instrumental technique, that the rupture of the unstable balance which makes the stick jump is manifested, according to the individuals, by a raising or a lowering of the tip: that is of no importance.

You know that dowsing consists of a discovery by means of a reflex movement: when the wand jumps into your hands, you know that you have found what you were looking for: therefore, it is useless to complicate such a simple thing by wanting to assign a meaning to the movement up or down. The stick jumps up or down according to various causes: minute difference in the elasticity of the branches, in the respective efforts of the two hands, in the nervous impulses of cerebral origin concerning the right hand and the left hand, etc.

36. - RADIESTHESIC RESEARCH BY MEANS OF THE WAND.

As soon as you are accustomed to the reflex of your wand, you can undertake any dowsing research.

Your first search will be for the coin you used for the training exercises; here's how to do it:

Have this coin hidden under a carpet or buried a few centimeters deep, depending on whether you operate indoors or outdoors; ask your helper to tell you in which direction you should walk to pass over the hidden room; walk slowly, in small steps, in that direction with the strong belief that you are looking for the piece in question and agreeing that the wand will jump when your right foot passes over the hidden piece.

It is quite obvious that you do not set out for research until you have taken the wand in your hands, holding it correctly.

Perhaps the wand will jump at some point on the carpet or the floor, far from the piece sought: it will simply mean that your hands, during the walk, have changed their position and the balance has been broken as a result of technical incident independent of the dowsing and not by application of your convention which associated this rupture of balance with the position of your foot on the part.

These failures should not surprise you nor above all discourage you: with practice, we arrive à maintaining the correct hold of the wand for a long time. Moreover, it should be noted that the good dowser prepares his research by asking the question carefully and by placing himself judiciously so as to remain under tension for the minimum time, the wand in hand.

37. - SEARCH FOR A DIRECTION BY MEANS OF THE STICK.

The rod occupies both hands: it is therefore impossible, when it is used, to operate, as we have learned in the study of the pendulum, by exploring space with the left hand as an antenna or with a cane. held in this hand.

The wandmaker uses the tip of his wand to create a line of exploration of space: this tip, which the ancients called the "flame" of the wand, determines a precise aiming sufficient for all operations. in which the method includes the search for one or more directions.

Aiming with the tip of the rod is well worth that which can be achieved with the left hand or with a cane:

one only has to look carefully in which direction the wand flame is while pivoting on the heels to explore all directions: at the precise moment the wand jumps, one notices and carefully marks the corresponding direction.

38. - RADIESTHESIC RESEARCH BY MEANS OF THE STICK: THE TORN DRAWING.

You have certainly understood how the use of the rod was going to modify the dowsing operation that we described to you in detail in § 6 of the first lesson in which the instrument, highlighting the reflex movement, was the pendulum: we suppose you are able to redo, with the wand, the search for the torn piece of drawing.

So that no error slips into the adaptation of this research to the use of the stick, we are going to give you, below, the complete description of the operation.

Preparation

Take a sheet of paper, approximately postcard size, and draw on this sheet a landscape, a flower or any object. After considering this design carefully, tear it into two halves and look carefully at the two pieces of this design.

Hide the right half of the drawing; your dowsing search will aim to find it.

As soon as the half drawing is hidden out of your presence, you take the left half of the drawing that remains in your possession and you place it on your left wrist (held by means of a rubber ring for example):

You pick up your wand.

First time

You say to yourself, thinking about it strongly: "I will look for the piece of drawing that I am missing" and you represent this piece to yourself as clearly as possible.

second time

Standing, you hold the rod, under tension, in unstable balance (see § 31) and you think: "The rod will jump when its flame is in the direction of the paper sought".

You will therefore have to explore the space by pivoting on your feet together.

Third time

You do this circular exploration by looking at the drawing to be completed which is on your left wrist and by aiming, with the flame of the wand, at everything that can be seen in front of you: you wait while swiveling for your wand to jump.

fourth time

As soon as the wand jumps, you stop your exploration:

the desired design is in the extension of the flame of your wand.

39. - IMPORTANT NOTE.

When you have succeeded in this research with the wand, compare it to the same research with the pendulum.

You will see that the only difference is, basically, limited to the movements of an instrument that you hold in your hands for the sole purpose of obtaining a planned movement.

However, the movements of the wand and the pendulum are caused by a rapid modification of your nervous system at the time of the dowsing discovery, modification which we call the divinatory disturbance. In fact, it is this disturbance which causes the dowsing phenomenon and it is to obtain it that we must, before taking the instrument in hand, define with precision the object of our research (first step: ask the question) and carefully choose the operating mode to apply so that the expected reflex is surely associated with the desired response (second step: choose the method and the reflex).

It is thus the first two times of the dowsing operation which are the most important: you cannot become a good dowser if you do not clearly understand this indisputable truth.

Working on dowsing for years is absolutely useless if each part of the operation is not attributed its true value: it is time, now that you know the pendulum and the rod, to rise above the techniques operations in order to discover the true face of our art; in any art we distinguish the knowledge part and the craft part. In dowsing, which is a way of knowing, it is not surprising that the knowledge part is primordial.

This is why we have, from the first lesson, presented the dowsing operation to you in a rational form of human operation requiring qualities of order, precision and judgment: there is, in dowsing, neither trick, nor mysteries: a well-conducted operation must succeed. In case of failure, if one employs a simple and logical method, one can discover the fault which causes the error and make progress by striving not to commit it again.

40. - RESEARCH ON THE GROUND USING THE STICK.

Everything that we said in the second lesson about research in the field is applicable to the use of the rod: the method that we have taught you is absolutely general. You will find the object, the goal of the search, by determining two directions passing through this point, each of these conditions being obtained in the following way:

Hold your wand in the seeking position (§ 31) and slowly pivot on feet together thinking strongly of the object being sought and agreeing that the wand will jump as soon as the flame is in the direction of the object.

As soon as the rod jumps, and at this precise moment, immediately locate the direction of the flame: if you have been surprised by the movement of the rod to the point of not being able to define this direction exactly, you will just have to start the operation again by coming back slightly backwards and pivoting very slowly, carefully aiming at a point far from the ground: for this precise determination it is not necessary to move the feet, the rotation of the bust on the hips is largely sufficient.

You know how to find a line by aiming with the flame of the wand, you know how to find a point by the very precise method of the right foot moving on this line: therefore, the search, on the ground, with the help of the wand, has no secrets for you.

41. - EMPLOYMENT OF THE WITNESS.

As the wand occupies both hands, you may be embarrassed to use a “witness” to better define the object of the research: if you are using a very small sample, you can very well hold it in your left hand without the correct outfit being hampered. If, on the contrary, it is a larger witness, you can attach it to your wrist as we advised you in § 38 for the torn piece of drawing.

In any case, we remind you that the witness does not possess, by himself, any selective virtue which can ensure the success of the research in an automatic way: it is the man alone who directs the research and carries it out. The cookie only serves to facilitate the operation by allowing the operator to ask his question with more precision or convenience.

Apart from this help that the dowser must know how to use, the witness, in our opinion, is perfectly useless.

Better still, we say that the witness is even dangerous because its use can create in the operator an unjustified confidence and make him relax the attention which alone ensures success; let us repeat that it is better, to find gold, to think of gold without a witness than to have a “gold witness” in hand and to think of... something else.

Consequently, we do not hesitate to advise the baguettetist to resolutely do without a witness: in fact, the operator who holds the baguette finds himself in a state of muscular tension and in an immobility of his body as of his instrument which constitute a state of expectation more characterized than that of the pendulist: this state of expectation which will cease abruptly by a general relaxation is eminently favorable to a single thought well oriented towards the object of the research. Strain your attention towards this object with care, as you deftly twist the branches of your wand, and you will be surprised at the rapidly increasing percentage of your successes.

42. - SEARCH FOR WATER BY MEANS OF THE STICK.

In this research, the rod presents an indisputable superiority on the pendulum and one understands that the old dowser who is at the origin of our dowsing art considered the rod as the most appropriate instrument for this research.

The technique is extremely simple: you have only to apply the principle exposed in § 22 of our third lesson; so here is how you should operate with the wand:

First case. - Search for water in a small area (less than 100 meters on each side for example).

Walk in a straight line crossing the field from end to end, the baton stretched in the waiting position (§ 31).

While walking slowly, think: “The wand will jump when I stand on the site of an underground stream”. As soon as the stick jumps, stop and mark the point on the ground with a stake or, simply, by making a sign on the ground with your right foot.

Continue your walk in a straight line as there are probably other water points to discover.

Then you travel new lines and you thus obtain, on each of your routes, a certain number of points under which there is water and where you can refine the search by operating as we described in the third lesson.

Second case. - This is a large area where such walks would be impossible or extremely long.

Stand at any point on the edge of the field and search, with a stick, for the direction in which the groundwater is located (see § 37). This direction being materialized by stakes or marked on the ground, you will look for another one by the same method: the intersection of these two directions will give you the place where you can operate as in the previous case of a small ground.

43. - GROUNDWATER LIMITS. DEPTH AND FLOW MEASUREMENT.

Just like with the pendulum: just think:

“The wand will jump” instead of “The pendulum will turn”.

44. - SEARCH FOR THE DIRECTION IN WHICH UNDERGROUND WATER FLOWS.

When you have traced the underground watercourse on the ground as it was said in § 22, you place yourself in the middle of the watercourse and you take the rod in your hands.

Hold your wand as if for research and walk slowly following the stream traced on the ground: your wand will jump immediately. Turn around and retrace your steps back to the starting point.

You will have noticed that, in one of the two directions of the course, the rod jumped much more easily and much more energetically than in the other: it is going up the current that the rod jumps with the most violence, this which is easily understood because it is by going against the current that you cross the most water for the same speed of progression.

In some cases (and more often with a hard rod) the rod jumps so briskly when going upstream that instead of making the usual quarter turn up or down, it makes a full turn. and comes back to the horizontal waiting position; as the hands have not moved noticeably, the wand jumps again and if the dowser is very trained to instantly catch up with the unstable balance, we witness this strange spectacle of a wand which turns indefinitely while going up the water like a wheel mill moved by the current. The dowser feels besides this odd impression of the current which makes turn a wheel: in the other direction, while descending the current, this impression does not occur.

We draw your attention to this particular point of the baguette technique: when the operator has achieved a certain virtuosity, when he feels his baguette to the point of giving him such mobility, dowsing becomes for him a source of joy of high quality: even with a soft stick, he obtains spectacular reflexes and he develops his sensitivity by constantly improving the handling of this marvelous instrument; the pioneers of dowsing do not

understood nothing, looking for preposterous explanations where one still finds corpuscles, radiations, occult influences, etc., whereas the reality is so simple: the rod is a cleverly combined spring to counterbalance a nervous tension of the man: she is nothing else.

45. - RETURN TO THE PENDULUM.

On the ground, the rod presents itself as an instrument of the first order, the best suited to dowsing research, especially to that of water.

But we will see that it is possible, and even very easy, to discover any water or minerals in a piece of land without having to go there, simply by working on a map, a plan or a sketch representing the field to be explored: for this so-called "remote" or "on-plan" research, the rod is not at all suitable: one hand must, in general, be free to manipulate a few devices. In these cases, the pendulum alone must be used: a complete dowser therefore uses the wand outside and in the search for illnesses on the patient himself, while he uses the pendulum in all other cases.

46. - THE UNIT OF RADIESTHESIA.

You could see that the change of instrument does not introduce any modification in the general technique of the radiesthetic operation; only the movements of instruments characterize the pendulum and the baguette. You must notice that the work of the dowser is the same in both cases and that, consequently, the discovery (sole purpose of the operation) is not the fact of the device but of the man himself: there are therefore not two dowsings, that of the pendulum and that of the rod, but only one that we have precisely defined, without speaking of any instrument (§ first):

“A means of knowledge that uses a conditioned reflex associated with the truth sought”.

PORTRAIT OF RADIESTHESIST

All the French officers prisoners at Oflag IV D knew Captain LE VAVASSEUR who was the convinced, enthusiastic dowser, always ready to attempt some new research.

We smiled a little when we saw this lively-eyed captain pass by, with his hair magnificently raised on a pure forehead, vibrant with activity in a camp where thousands of comrades stagnated in their boredom... people smiled because, instead of a sabre, this disarmed infantryman wore on his left side, suspended from his belt, a thin cloth case serving as a scabbard for a wand of a rhabdomancer, of a dowser, as those who want to speak modern say.

If he was asked to come to the barrack theater or to a sports match, he almost always replied:

“I don't have time, I still have several to treat”. so many others, discovered on small things, this immense truth: I am capable of discovering. This observation in a man endowed like LE VAVASSEUR with an imperturbable practical sense and an active Christian charity was to lead him to a more active activity. smarter and more useful than looking for an upturned card on the table or the number of beans in the can of cassoulet.

Without reflecting and without believing himself specially marked for the successes of radiesthesists, he perfected himself in an art where others are satisfied with an almost sterile one. He quickly arrived at a sure diagnosis and found that the patient he was interested in very quickly felt a slight

improvement in his condition. Having no medicine (and having no medical knowledge), he had, in short, only his head and his hands he wanted to use his hands as well and, simply, without even using the term "magnetism", he placed his hands on the diseased area that his wand had just indicated.

The results were fantastic, it decongested the livers, calmed the pains and reduced the inflammations:

But the most extraordinary thing was that the contact of the hands on the patient's body proved useless.

Following the captain with the whale saber we saw the following scene: standing in front of the patient, he examined him from head to foot, then, making him sit down, asked for a stool for himself: and then the mute scene that the "barrack watched with judgments that we can guess were diverse: THE VAVASSEUR, his hands stretched out towards the guilty organ, scrutinized, through the paramilitary rags, the return of normal functions which would restore health to this unknown comrade whom he called his brother.

This is how dowsing and magnetism were discovered and used with rare happiness by an officer as devoted as he was modest, defying ridicule in the accomplishment of a mission he had freely given himself: he did not lose a minute to seek explanations since the simplicity of his technique and the clarity of his mind allowed him to walk without stopping towards this immortal goal of human desires: perfection.

What a magnificent lesson for those whose success is often based on words and what encouragement for novice dowsers who will consent to operate in all simplicity, without unnecessary complication with regard to equipment or thought!

Captain Marcel LE VAVASSEUR has proven (others as well) that the confirmed dowser, in full possession of a logically established technique, absolutely does not care about the opinion of those around him and that he has no need, as we affirmed it too lightly, with a sympathetic atmosphere.

Disinterestedness in regard to public opinion is necessary in all art in general and in ours in particular. Let us repeat on this occasion that the dowsing is not a game of chance but a means of knowledge of a special technique.

Work seriously, without fear of the ridicule of the ignorant, in order to acquire a very human faculty which will allow you to better serve your contemporaries.

The stick in the side perhaps, the pendulum in hand when it is useful, but the love of the neighbor in the heart, always.

Love is also knowledge, said Saint Jerome.

You are certainly wondering what has become of this modest hero. Alas! Barely returned from captivity, when he had been appointed commander and a good career, civil or military, was offered to him, he died while fishing, not far from a place in Normandy, exactly the place where his father had died in the same circumstances fourteen years before.

The dowsers must honor the memory of one of their own who was, in the full meaning of the word, a good man.

FIFTH LESSON

ORIENTATION WITH THE PENDULUM AND THE BAGUETTE

47. - DEFINITION

The problem of orientation by the pendulum is that of the search for a direction allowing to orient oneself when one is lost in the countryside or in a forest: one can seek the direction of the north which, once found, is enough in general to determine the direction in which you have to walk to find yourself on known ground: you can also search directly for the direction in which the neighboring town is located.

You certainly think that these two searches (from the north or from the neighboring town) must be done according to the same principles as the searches for directions already learned during the previous lessons: you are right but the problem of orientation is everything similarly special as you will see in the next paragraph.

48. - THE NEUTRALITY OF THE RADIESTHESIST.

From the first lesson, we have drawn your attention to principles of paramount importance, in particular this one (§ 9):

Observe complete neutrality, i.e. do not imagine a particular solution

If it is very easy to remain neutral during a search for lost jewels, ores, etc... when it comes to finding the road to your house or the direction of the north that will allow you to get closer to it, it is not always the same. Often you hesitate between various directions, but it seems to you that such a direction is the right one:

In this case do not count on a dowsing operation to get you out of trouble: you would inevitably find, with the pendulum or the rod, the direction which seemed to you to be the good one.

In other words, dowsing cannot "verify" what you believe to be likely: according to its nature of intuitive knowledge, it can only provide you with the truth in the event that you cannot formulate any hypothesis: one of our students said precisely: "One can orient oneself with the pendulum (or with the rod) only when one is completely lost".

Therefore, the very character of dowsing obliges us to act in the following way: if we are lost and if we doubt the right path, we must not take our pendulum (or our wand) before having tried all the roads that seem suitable to us:

After having seen that we made a mistake, we inevitably become neutral in the face of the problem of orientation and we can operate under excellent conditions.

49. - ORIENTATION BY THE PENDULUM.

To look for the direction of the north, place your body quite straight and raise your left arm in antenna as we have already taught you; give a slight swing to the pendulum held by the right hand: pivot slowly around the joined feet thinking strongly: "My pendulum will turn when my left arm will be in the direction of the north".

As soon as the pendulum turns, look carefully at the direction indicated by your left hand: it is the northern one.

Remark. - Always think of geographic north, which is better defined and more easily represented than magnetic north.

If, as is desirable, you have a compass and if you do dowsing orientation exercises during walks with complicated routes, the compass will allow you, after the dowsing search, to control your result.

It is quite certain that the same method applies for the search for the south, the west and the east: we advise however to search only for the north and to deduce the orientation by this cardinal point which is obviously a prime direction.

50. - SECOND METHOD.

Many dowsers use a different method that we give you here as documentation.

They start their pendulum in rotation by agreeing that when the rotation stops, the pendulum, starting to oscillate, will indicate the direction of the north by oscillating towards the north.

This method is very inferior to ours for three reasons:

- 1) It uses a reflex different from that which we have recommended, which reduces the safety of operations since the expectation of an oscillation in an unknown direction cannot be a single reflex: on the contrary, the reflex movement which we recommend (change of oscillation in rotation) is suitable for all cases by adapting to a very simple method;
- 2) It defines a direction by a plane of oscillation, which defines it very poorly since the same plane can indicate north as well as south;
- 3) It does not take into account a physiological fact which has escaped almost all dowsing authors: the oscillations of the pendulum, caused by the movements of the hand, do not occur with the same facility in all directions. There is here a cause of error which, by itself, must condemn this second method.

51. - ORIENTATION BY THE STICK .

To search for the direction of north using the rod, hold your rod as prescribed in § 31, but keeping it a little higher than for a search involving the subsoil: in this way you can, with the flame of the wand, aim almost horizontally. In this position, you slowly rotate around with your feet together thinking strongly: "My wand will jump when its flame is in the direction of north".

52. - SEARCH FOR VARIOUS DIRECTIONS .

When one is lost in the countryside or in the forest, one can instead of looking for the direction of the north, looking for the direction of a city, that of a known house, that of a group of people that one must join, that of his car whose position we no longer remember, etc.

Our method of research, by the left hand in antenna when we use the pendulum, or by the flame of the rod when we use the rod is absolutely general: there is only to replace, in the convention ordering the reflex, the direction of north by the one you want to find.

53. - ORIENTATION EXERCISES.

It is quite certain that the real orientation exercise can only be done if the direction of north is unknown:

this case does not occur only during a walk where you have lost your way and when the veiled sun cannot give you any useful indication. During a visit to a house you do not know, after having turned up a staircase and through different rooms, it often happens that you are undecided on the exact orientation: then take a pendulum or a rod and, after having obtained the north direction, check it by compass.

You can also do an exercise which does not offer the same interest in discovery, but which trains you to obtain very precise directions: all you have to do is look for north in a place that is not very familiar to you and where, while knowing approximately its direction, you will practice to achieve a perfect pointing: by checking with a very sensitive compass (pivot under agate cover) you will be amazed at the precision at which you will arrive.

When you have thus disciplined your reflex, you will have definitively acquired a speed of response which will put you in a position to operate with certainty in much more delicate research which requires measurements, as we will soon teach you.

54. - RADIESTHESIA AND THOUGHT.

This lesson brings you little new from the point of view of pure technique, but you will realize, by studying it and by practicing the exercises which it proposes to you, the extraordinary importance of what the operator thinks. The dowser is neither a machine nor a receiving device analogous to those that everyone now knows: when he holds a pendulum or a rod after having properly posed his question and the convention of reflex movement, his thought explores the neighboring terrain or the entire space and realizes the discovery.

If you pose the question badly, if you have not clearly agreed when the reflex must occur or if you are not neutral with regard to the result, your dowsing operation has failed: these three faults are faults of thought. .

You must now understand what the mentality of the serious dowser should be:

Simplify the operation to the extreme in order to be able to think clearly of all its successive points;

Choose, for all his life as a dowser, a single reflex which will become automatic by allowing an absolutely clear convention.

We hope that all our readers will appreciate our effort at simplification which has brought clarity into a domain where it did not shine: some are surprised to see the place given to intellectual work in a practical course in dowsing: this is due to the very nature of the dowsing which, itself, obviously depends on the nature of the dowser.

You have already learned to search for objects or truths of all kinds, always with the same instrument and by the same gestures. What differentiated this very diverse research? Your thought, only your thought. It is she who conducts the operation and carries it out: this is why we repeat to you insistently: what you think is more important than what you do. Have this truth always present in mind at every moment of the dowsing operation.

LESSON SIX

ON-MAP RESEARCH

55. DEFINITION OF RESEARCH ON PLAN.

You all know that by simply working on a plan, dowsers manage to indicate precisely where a misplaced object or a missing person is. These successes have always astonished the public, even dowsers who have not tried this kind of research because they believed it to be extraordinarily difficult.

We are going to teach you, through this lesson, how to carry out this research: you will be able to say to a consultant, without leaving your office:

The bicycle that was stolen from you is now on the road from Montereau to Sens, 4 km away. of Meaning”.

Or: “The person you are looking for is now in Barcelona, Spain”.

The operation which allows you to obtain these results, so astonishing that many do not dare to believe it, is done at the place where you will find yourselves, at a distance which can be very great from the object or of the person to seek: this is why one called this kind of dowsing research the “tele dowsing”. This name has become common, but we much prefer "research on plan" which perfectly characterizes the operation.

56. WHAT IS A PLAN?

Before embarking on a "plan search", it is essential to know exactly what the "plan" is. You read in the Larousse that a plan is the representation of an object, in small, on paper. You will see the following example: the map of a city.

Everyone knows the plan of his city and can, for better or worse, draw the plan of the accommodation in which he lives.

On the other hand, you all know how to follow the riders of the Tour de France on the “tour map” which is a map representing the route of the race.

However, to fully understand dowsing research on a plan (we cannot succeed without it) it is necessary to know precisely how a plan is used: the use of the plan has become so common that we no longer go regardless of what we do with it.

The plan of a lot can replace the lot to designate a point: for example, if you ask an owner where the well of his property is, he can answer you by showing you only a point on the plan of this property (and this, at any distance from the property): you yourself, by looking at the plan, will be able to know that the well is at the bottom of the yard, to the right of the garage, near the vegetable garden, etc. The plan which carries the garage, the vegetable garden, the fences and the buildings informs you completely by fixing the designated point compared to the others which are represented there.

Another example: you can be given the position of a motorist by showing you a point on the National Road N° 7 represented on a map of France: you look at the towns closest to the point indicated to you and you see that the motorist is between Fontainebleau and Moret-sur-Loing: he is thus perfectly localized since you know its position in relation to the two cities.

57. PENDULUM SEARCH ON A ROUTE.

We will describe the operation to you by an example.

Suppose you want to find the current position of a traveler who is going from Lyon to Nice by Route Nationale No 7; you have the photo of this traveler.

The necessary material consists simply of a pencil, a pendulum and a map of the Lyon Marseille region.

Place the Lyon Marseille map on your desk and, to the right of this map, the traveler's photo. Take the pencil in the left hand and the pendulum in the right hand: the operation consists in following the Lyon Marseille road with the point of the pencil by making the following convention: o My pendulum will turn when the point of the pencil passes by the place of the road where the traveler whose picture I have in front of me is currently located".

You do this "scouting" of the route slowly, carefully looking at the route on the map and occasionally glancing at the photo.

The only difficulty lies in the fact that you have to follow the road always thinking of the traveler represented by the photo.

As soon as the pendulum turns, you mark the point on the map and then you know where the traveler is.

58. SEARCH IN CASE NOTHING IS KNOWN.

This is obviously the general case: we are then obliged to explore the entire map of the region where the object or person to be sought may be found.

Let's explain the method with an example. Suppose someone comes to tell you that a child is missing and asks you to look for him.

Fig. 5. — Le chercheur transparent

You are given a photo of the child and you place it to the right of the map of the region.

The necessary material is: a transparent researcher, a pencil and a pendulum.

The operation is done twice.

1. Explore the map by moving the researcher, flat, with the left hand, sliding on the map so that its rectilinear edge runs from one end of the latter to the other: you do this exploration, pendulum in your right hand, agreeing that the pendulum will turn when the rectilinear edge of the researcher passes over the point where the child is, defined by the photo.

As soon as the pendulum turns, immobilize the transparent seeker.

2. Find the place where the child is by following, with the pencil, the rectilinear edge of the transparent finder as if this edge were a road (§ 57) agreeing that the pendulum will turn when the pencil passes over the point where the child is. child defined by the photo.

As soon as the pendulum turns, immobilize the pencil and mark the point.

59. REMARK.

If you don't have the transparent finder scope, you can explore the plane with a ruler or with the edge of a tracing paper, but, to make the operation quick and easy, we use the colored transparent finder scope which does not hide anything from the map and clearly separates the explored part from the unexplored one.

60. GENERALIZATION OF RESEARCH ON PLAN.

The dowser can search for everything on a plan, on a map or even a simple sketch which does not have the precision of a map: this is what is expressed by saying that teleradiesthesia can be applied to all research. You can therefore, on a map, search for an object, a body of water, oil, gold, caves, etc. You just need to have a map of the region concerned and to operate as we have taught to find a person. You will notice how much all the dowsing operations on a plan are alike: the important thing is to think carefully about what you are looking for. The role of thought is crucial: it is thought that will seek information where it may be, whether near you or hundreds of kilometers away. The dowser's equipment therefore only aims to make the operation quick and practical: it is only from this point of view that it is very interesting.

Première opération : Le chercheur est immobilisé dès que le pendule tourne.

Deuxième opération : Le pendule tourne quand la pointe du crayon glissant sur A-B passe sur Souppes qui est le point recherché.

Fig. 6

61. LET US CITE FOR EXAMPLE A SUCCESS OF THE FAMOUS RADIESTHESIST G. TREYVE.

Coming out of the Paris Opera with a friend, he noticed that his car had disappeared. He rushed in a cafe where his friend saw him take his clock, work for a few moments on a map of Paris, then telephone. G. TREYVE quickly dragged his companion towards a taxi, saying to the driver: "Porte d'Ivry, we're going fast!"

The thieves did not understand what had happened: simply a phone call to the police asking them to stop the car 793-73 which had just been stolen and was heading towards a southern gate of Paris, probably that of 'Ivry.

This is how TREYVE had operated: he looked on the map for the direction taken by the car by turning his pencil around the Opera, then he looked for the exact position of the car at two successive moments, which enabled him to give indications enough for the police.

You must well understand the way of operating of this great dowser; we will add that it is not necessary to use a "witness" to define the car to be searched:

For a motorist, "my car" perfectly defines the object of the search. It would be a big mistake to use the gray card or the key: it would be preparing distractions harmful to the success of a fairly easy operation.

62. WHICH CARDS OR PLANS TO USE?

Obviously, we can't tell you which maps or blueprints you should choose to search for a lost item or missing person.

In general, you risk nothing by starting with a planisphere, even in the case where the object cannot possibly be far from its starting point.

To give you an instructive example, we will quote one of our researches from 1947.

A Parisian, Mrs. de N..., writes to us to ask for a search for a very beautiful emerald (ring), lost for a month, and to which she was very attached.

The first search on a map of Europe gives Dijon. The second search on the Michelin guide (map of Dijon) gives the angle of rue X.. with rue Y...: one of the four corner buildings.

We write this result to Mrs. de N. who replies that she has an apartment in this building: we then ask her for the plan of the apartment.

The third search on the plan of the apartment gives a point that we mark with a cross.

We announce this result to the happy owner of the emerald who answers us: "I will look for it. I will keep you posted".

Eight days later, we receive a letter saying that the emerald was found but at 0 m. 36 from the place indicated by the cross. We replied to Mrs. de N... that this error was due to a fault in the plan (partition offset slightly). And that was the end of this perfectly normal search.

We looked for "the emerald lost by Mme de N..." without "thinking" of anything else and without the slightest witness.

63. DEFINITION AND TIME.

When you are looking for a jewel, a bicycle, a car, etc., do not attach yourself to the general characteristics of the object but on the contrary to what individualizes it. If you cannot be given sufficient details about the individuality of the object to be searched for, just define the object as we did for the emerald in § 62: the necklace lost by Mrs. X.. January 6, 1953... the car stolen from Doctor P.: such a day, etc. These definitions are accurate and cannot direct your search to false leads. The designations: gold ring, Peugeot 203 car, are more dangerous than useful since they define a quantity of objects other than the one you are looking for.

In summary, never forget that the big difficulty in dowsing is to "ask the question" so that the solution is unique: it is then exact.

time error

When you are looking for an object or a person, you must ask your question at the precise moment when you are operating. We made you say in § 57 "the place of the road where the traveler is currently located"...: let us insist on the enormous difference which exists between the search for a body of water and that of a traveller. Within years or sometimes even centuries, the water table remains the same while within an hour, the traveler changes location. An inaccuracy of time, in your search, will inevitably produce a location error in the result of this search:

It is because of ignoring this observation that operators have collected failures to the point that they have given up or tried to explain their failures by high fantasy hypotheses.

64. ADVANTAGES OF RADIESTESY ON PLAN.

You have certainly been struck by the extreme simplicity of our plan search method: in this regard, we can assure you that we know a large number of different operating procedures. If we do not mention them in this course, it is only because it is a Practical Course and not a collection of all that has been written on dowsing. We pass over, therefore, other processes which are unnecessarily complicated or error-prone.

It was important to develop a simple and practical method of research on the plane because (you will certainly agree with us) the research on the plane is the true dowsing of an absolutely general use, placing the operator in situations always the themselves and providing him with ever-increasing mastery if he understands what he is doing.

The neutrality

We have warned you against errors arising from a suggestion or a mere supposition which may occur to you while examining the ground which you traverse with the pendulum or the wand. Reread § 28: "Perform your search for water without taking into account what the examination of the ground might suggest to you.

When you look for water on a map, the terrain can't mislead you: you don't see it.

Nothing is neutral like a piece of map and if you are looking for a cave, an ore..., you do not risk the frequent errors of those who are deceived by a fault without interest or a piece of ore that comes by chance.

It is undeniable and the abbot MERMET clearly affirmed it that the dowsing on plan removes a very great number of errors due to a lack of neutrality; we will see the application

truly marvelous in medical dowsing. This advantage alone should push all dowzers towards this branch of their art.

Limitless possibilities

The fact of being able to carry out any research without leaving its work table and in an insignificant time constitutes for the dowsing on plan an extraordinary superiority. No need to go there, hence an unexpected saving:

We are not bothered by forests, streams, lakes, fences of all kinds.

The great distances have absolutely no importance: The dowser discovers as easily what he is looking for thousands of kilometers away as under his feet.

Some readers may wonder why, pushing our desire for simplification to the extreme, we have not contented ourselves with exclusively exposing this prodigious "research on plan". There are two reasons that justify our way of doing things:

1) Some field research cases are so simple that it would be ridiculous not to know what you have already learned;

2) It is better to learn the trade of dowser in the field, if only to obtain clear and violent reflex movements from the start of training: indeed, many operators find it difficult to properly represent both this what they seek and the ground where it is when the latter is figured only on paper: their spirit demands more concreteness. After many successful operations in the field, they no longer think about the method that has become habitual to them. Their thinking becomes much more active and can work just as easily in the abstract.

They then become true dowzers, capable of making the best use of the intelligent faculties which essentially distinguish them from their inferior brothers the animals: the companion of Saint Anthony can only look for truffles near trees and that of Saint Roch cannot find his master by means of a card.

65. AN EXAMPLE OF PLAN SEARCH.

To end this lesson which we hope will be valuable to you, here is a research full of lessons that we carried out in December 1952.

We read in Le Figaro that they are looking, in the forest of Fontainebleau, for a little girl who has been lost since the day before (4 p.m.). It was 9 a.m. 45 when we read the article which left little hope of finding her alive because the temperature had been held at night between -5° and -10° . Journalists and the hundreds of police, civilians and soldiers who had taken part in the fruitless search, thought that the little one, having moved away from the place where her parents, florists in Saint-Mandé, were looking for moss, had crossed the road and had been run over and then hidden in the forest; yet the excellent police dogs of Melun had found nothing.

At 10 o'clock, our phone rings and the girl's father asks for our help; we beg him to come to our house as soon as possible.

The operation is proceeding normally. As he had no photograph of his daughter, we ask the father to give us the name and address of the little one, which defines her perfectly.

We start with the most urgent, and in a few seconds of work with the universal protractor (you will do it soon), we affirm: the child is alive, she does not even have a cold!

How is she dressed? The father, beaming, tells us that they had bought him, the day before, an anorak, a woolen cap, etc.

We answer: now, go find her. A transparent researcher's passage on the map of the forest and a pencil path (see above § 58) gives a point which we show to Mr. CHABERT, father of little Nelly, who seems skeptical: "It's two miles from where we lost sight of her! ". We answer him: "She is there: do not waste time and call me to give me confirmation of her state of health, incomprehensible but certain".

Shortly after, Mr. CHABERT telephoned: "I have my daughter... she is in perfect health... at the precise place you indicated!

Curiously, Mr. CHABERT found his daughter in the arms of a policeman from Dammarie-les-Lys who came to reinforce the search teams: it was while passing 1,800 meters from the probable place that this policeman saw a child quiet under a tree and who says to him: "You come very late, I haven't had lunch... A big animal came and licked my face during the night...".

This search, which did not last more than three minutes, left us with pleasant memories and a kind letter from the florist confirming his telephone thanks:

We have told it to you because it contains lessons of primary importance.

a) Neutrality. The results found were absolutely contrary to common sense: a three-year-old girl spending a night outside below -5° without catching a cold and finding herself the next morning 1,800 meters from where her family had stopped . These results were so absurd that no one believed her to be alive and that the search had not been pushed to such a distance. The dowser must be completely neutral, that is to say expect everything, imagine nothing and state coldly what he finds, even if it seems to him stupid: he finds the truth only under these conditions.

b) Security and simplicity. When one employs a clear and simple method like ours, it is possible to follow all that one does and one quickly arrives at a security in the results that few dowsers dare to hope for. When we assured M. CHABERT that little Nelly was in perfect health, we saw a man sobbing headlong and we saw him like this with no other feeling than joy: we were sure of ourselves, without that. ...

c) The possibilities. It is useless to insist on the possibilities of research on a map: let us simply add that the forest in the region concerned is an immense chaos of rocks, tall ferns, bushes and tall trees which make it impossible to walk in a straight line, straight sights, materializations of directions... In such terrain, it is very easy to escape a hunt even organized by specialists: on the other hand, well-made plans exist where some curious rocks are marked by marked points: the dowsing on plan had there a privileged application.

d) Public education. You who have followed our teaching, remember what we said about research carried out in the field with the left hand "in the antenna": if the florist had known these easy procedures, he would have taken his watch as a pendulum and would have sought the direction taken by the child (who walked for hours). That would probably have been enough to approach her within earshot when she was called to far away from her actual position. Finally, in case of failure by this process, he had the card!

Note that a father looking for one of his family finds himself in a privileged situation to think of the person sought compared to a dowser who does not "know" him even by a photograph.

You will therefore be of our opinion: it is necessary to spread in the public the true knowledge of dowsing, a marvelously effective means of discovery which it is painful to see so little used.

Therefore, dear readers, read carefully and make read our course which was not created for any other purpose than that of rendering service.

66. - THE TESTAMENT OF Miss HARRIET HALLOWEL.

Let us give one more example of plan research which, we believe, will be of use to many readers. Here is a detailed account of an operation we did in 1946.

Sir,

“An American living in Moret died there in 1943.

Her close relatives who live in America are convinced that she made a will which, hidden in her house, they believe, has never been discovered.

" They ask me to do everything possible to find this paper. I have therefore thought of asking for your assistance and I shall be obliged to you to tell me if you would agree to carry out this research.

The deceased lived in two very old and important juxtaposed houses which are part of the city's fortifications. It is therefore difficult to draw up a plan.

P.”

I immediately phoned the signatory of the letter that I would gladly undertake this research and the same day the car of Mr. Louis PARENT, former clerk, administrator of the estate of the American, took me to Moret.

Moret-sur-Loing is a charming tourist resort 11 kilometers from Fontainebleau. The two houses, inhabited until 1943 by Miss HARRIET HALLOWEL, are old residences where considerable work had been done to make them the dream home of an artist: the deceased was, in fact, an excellent painter and engraver. The walls separating the two houses were pierced by several openings and the rooms together left no traces of the separations visible, so much so that by climbing the stairs of the house on the left, one could not tell whether such a room belonged to this house. or the one on the right: complete entanglement up to the second floor where a huge workshop covered the two buildings. By visiting the places with Mr. PARENT, I understood the difficulty of drawing up complete plans of these dwellings.

Mr. PARENT told me that, according to certain information, the will was in the cellar, in a hiding place: he provided himself with the necessary tools and we went down to the cellar where I looked for "a will signed by Miss Harriet HALLOWEL": I determined two directions that intersected outside the cellar and I decided to go back up.

The houses, uninhabited for almost four years, were freezing, the one on the right absolutely empty, the one on the left, elegantly furnished on the ground floor, served, on the first floor, as a storage room to the point that penetration there was very difficult. difficult.

Under these conditions, I decided to give up research on the spot and to return to work, in the warmth, in my office in Fontainebleau: the process chosen was the following:

- Make a sketch of the ground floor of the two reasons, which was easy;
- Look, on this sketch, with the pendulum, for the vertical projection of the will in question;

- Finally, determine, using the pendulum, the floor where the will is located.

The sketch was done in pencil in a few minutes, carefully noting everything that could serve as a benchmark to fix a location: doors, windows, cupboards, furniture, etc...

After taking a much appreciated grog, the operation was done in less than a minute, the will was discovered in the house on the left, as shown in figure n° 7.

And I telephoned Mr. PARENT: "I have the will: we will go and get it when you want".

- Do I take picks and pickaxes?

- Useless: it is in the left house on the first floor, above the living room, a few centimeters above the floor. Only bring someone who knows English well.

- You surprise me a lot since we have been looking in the rooms of the two houses for four years, but we will go the day after tomorrow".

Two days later, I went directly to the spot and I said: "It's there, in this crate".

Mr. PARENT then said: "I understand: the secretary here has a secret that we have not found and certainly...".

I glanced out the window to check the plumb of the point found on the ground floor plan and repeated:

" It's in the box: the secretary is a yard from the point I found and I can't be a yard mistaken; location was easy thanks to the niche in the living room and the door to the first floor located exactly on the one on the ground floor".

At my insistence, and without enthusiasm, Mr. PARENT, Mrs. PARENT and Mr. TOURAUT, bailiff at Moret, kindly helped me explore this box full of books and notebooks:

Leafing through a notebook, Ms. PARENT dropped a long envelope from which she took out a piece of paper folded in three, which she read gently:

IN CASE I DIE IN MORET I WISH...

Sign. Harriet Hallowell

Fig. 7

We immediately went to Mr. LEJEUNE, notary in Moret, to whom the will was given to be inserted in the file of the succession.

You have certainly guessed how I discovered that the will was on the first floor: simply by drawing a rectangle representing the house on the left and looking on the pendulum for the floor where the "Will of Miss Harriet HALLOWEL" is located. Figure no. 8 represents this rectangle: the height above the floor was naturally measured with a universal protractor.

Note 1. We gave this example because it shows the immense advantage of the search on plan:

And again, it would be necessary to insist on the exclusive advantage of the

Fig. 8

neutrality. We ask professional dowzers and experienced amateurs to appreciate the difficulty presented by the search in the cellar when the first direction found seemed to indicate a brick surrounded by plaster towards which Mr. PARENT went immediately and when the second direction was not to not recut the first on this brick: let us repeat that, without absolute neutrality, no dowzing.

Comment n 2. Our best memory of this affair was Mr. LEJEUNE's thanks: "Thank you, sir", as simple and as natural as if an electrician had repaired his bell or a plumber his sink. Far from being astonished, we consider on the contrary that one day, when the dowzers know their job, they will be called like the plumber or the electrician to learn that an intestine is clogged or that a gland does not produce enough. ..

Note n 3. A moment of emotion: a month after this research, Mr. PARENT telephoned us: "The will is worth nothing: the heirs died before Miss Harriet HALLOWEL: she therefore made another that would have to be found".

After ten seconds of reflection, we answered that this second testament we would have found it: a new search is useless.

We were right: the will is worth nothing in France, but is excellent in America where "the dead inherit", that is to say that the descendants of a dead heir themselves become heirs.

Note No. 4. There were five wills in the house signed Georges HALLOWEL, Sarah HALLOWEL, etc. They didn't bother us because we were looking for a will signed Miss Harriet HALLOWEL. Please note in this regard the precision of the thought and the absurdity which consists in entrusting with this delicate function any "witness" or a magnet or radium (!) or other hardware that is inert but dangerous because the attention given to it, while being useless for the operation, is to the detriment of that which is necessary.

Remark No. 5. We will be believed, we think, when we assure that the preceding research has been given with a view to providing practitioners with an example which may be useful to them in the event of operations occurring under inconvenient conditions: our method always makes it possible to overcome it.

We have the deepest contempt for the "golden books" (for ours as for the others): we will only point out, in passing, that the operation related above had as witnesses a clerk, a bailiff and a notary, which is quite amusing. In addition, it was necessary to announce by official act, the unusual way in which an important document was added to the file.

Let us add to conclude that M LEJEUNE also asked since it is so easy "that we find for him the title deeds of the two houses and "the archives and accounts of the Society of the Daughters of the American Revolution: Rochambeau section". done the same way in January 1947, warm in our office in Fontainebleau, while the snow covered the houses of Moret where, in cupboards full of dusty files, business papers were hidden from the eyes of the lawyers but could not escape the discovery of an experimental and human dowsing at the same time.

LESSON SEVEN

MEDICAL RADIESTHESIA

67. - FOREWORD.

Much has been written on medical dowsing and recent articles have shown that there is not even agreement on the definition of the acts which can be included in this subdivision of our art.

In order to build a definitive construction and to cut short all idle discussions, we will begin by defining the objects of our study: when we have established the technique of medical dowsing and demonstrated its possibilities, we will expose our position - which is very clear - with regard to this controversial subject.

However, we can immediately do justice to an untenable opinion which has nevertheless been published: the dowser can discover certain truths in some fields but that of medicine would be forbidden to him! This is truly absurd: one could discover a cave in a basement, but not in a lung, a fissure in the ground, not that of an anus?... The doctor who professes this opinion reminds us of the one who refused us the possibility of discovering a missing toe on an anatomical board, but who, a month later, asked us to look for his watch, which had just been stolen from him, on a map.

68. - DEFINITION OF MEDICAL RADIESTHESIA.

We group, under the heading "medical dowsing", all the dowsing operations which relate to the state of health of the human being. As the radiesthetic operation is always a discovery, one can define the medical radiesthesia: "The discovery, with the pendulum or the rod, of all that interests the health of the man

This area is very broad. He understands:

- 1) The measurement of the numerical elements that characterize health: vitality index, pulse, temperature, blood pressure, number of red blood cells, various levels of urea, cholesterol, etc...
- 2) The discovery of the affected organs and the functions which undergo a slowing down or an exaggeration (hypo or hyperfunction), the location of the foreign bodies absorbed or introduced by trauma, etc.
- 3) The diagnosis, that is to say the classification of the patient in one of the categories of known morbid states.
- 4) The discovery of the remedy or remedies whose application is necessary in order to return to health: the choice of useful foods and the search for the right conditions of life.

69. - DIAGNOSIS.

Reading this list of four points, it seems that the first three are of little interest compared to the fourth, which solves the problem of health by curing the sick and teaching him to avoid illness. Indeed, the details relating to various organs are of no interest if the cure can be obtained without one being obliged to know them.

Any gifted dowser with critical sense made this remark: he concluded with the uselessness of the diagnosis in dowsing.

70. - MEDICAL DIAGNOSIS .

The diagnosis is necessary for the doctor who can generally know the remedy to administer only after having observed clinical signs, defined the corresponding disease according to his professional knowledge and, finally, chosen the therapy among those which are usual at the time of diagnosis. medical exam.

We know the particular characteristics of the diagnosis which differ according to the class of the operator: we can say, in a simplified form and with enough accuracy, that the diagnosis is clinical, symptomatic or causal depending on whether its author is an allopathic doctor. , homeopath or medical dowser.

Doctors admit that the diagnosis is a necessity caused by the impossibility of finding, from the outset, the remedy suitable for the patient: it is also a "psychologically necessary formality of passage because the patient wishes to know what he has" (Dr. Aug. Ladon). In our opinion, this second point is the consequence of the first: the patient trusts the doctor for therapy, but if he is reassured when his doctor has discovered the illness from which he is suffering, it is because he knows the method of doctor and if he wants to know what's wrong with him, it's a lot to be sure that the doctor knows it himself.

The question arises differently for the client of the dowser who does not understand anything about the way in which this one operates and is therefore willing to passively accept the following order: "Take such a thing in such a way and you will be cured".

71. - RADIESTHESIC DIAGNOSIS.

Although he can obtain immediate knowledge of the appropriate remedy, the dowser must know how to establish a diagnosis, if only to help the doctor.

Note that the diagnosis of the dowser can be causal, but it is not in all cases, as some colleagues seem to believe.

The causal diagnosis which determines the cause of the evil and, consequently, makes it possible to attack it at its roots, is discovered by the dowser who asks the question accordingly. If the latter is satisfied with "noting the damage", he will make the same diagnosis as the attending physician, who has long since abandoned the search for morbid causes, research which he classifies under the label "etiology".

72. - THE AGREEMENT OF DIFFERENCES.

One should not be astonished to see doctor and dowser providing, for the same patient, at the same moment, different diagnoses: that simply proves that the dowser has done his job conscientiously, with the maximum of efficiency and that he has discovered the cause when the doctor could only observe the effects.

It is under these conditions that the doctor's science will come into full light because he knows if a causal relationship unites the two observations: he can therefore simultaneously verify the conclusions of two specialists operating separately and differently; then, applying the medical Knowledge which he alone possesses, he can, without fail, attack the cause and neutralize the effects.

The dowser must know how to carry out the causal diagnosis which he alone can obtain in all cases.

We see that the discrepancies between the diagnoses of the doctor and the dowser are eminently beneficial to the patient: these discrepancies, far from proving the error of one of the judges, can, on the contrary, demonstrate their virtuosity.

Consequently, that fixes us absolutely on the dowsing value of the doctors who say to verify, by the dowsing, their medical diagnosis.

73. - COMPETENCE OF THE RADIESTHESIST.

The dowser can discover what he wants to discover:

He is therefore capable, at the first stroke of the wand or of the pendulum, of finding the remedy suitable for the patient and then the dose best suited to the particular state of his client.

A large number of operators are not looking for anything else, acting, in short, like the animals themselves:

They imitate their lesser brethren whose instinct is not warped by the servitudes of human nature which are:

Credulity, superstitions, abusive advertising and charlatanism.

We knew in captivity the dowser S..., the best medical dowser, in our opinion, who placed his patient in front of bags of plants then chose and dosed with the stick the infusion which suited him. There are many who, like us, have taken advantage of this ultra simple and perfectly used technique.

However, not all cases are amenable to this technique: some patients must be surgically freed of some foreign bodies or tissues whose condition becomes dangerous for the whole organism. On the other hand, it is advantageous to know, by a measurement, to verify the progressive disappearance of a deficiency: the dowser must know how to take a temperature, follow the evolution of the index of vitality, etc...

Consequently, the list with the four points, established at the beginning of this lesson, represents well the program of study of the medical dowser who wants to render service within all the limits of his competence.

This list is obviously established taking into account the usual techniques of the doctor, but it happens that it groups, in each of its four points, research which, from the point of view of dowsing, is absolutely comparable: we will therefore remain subject to the requirements of a logically ordered presentation by studying these four points in turn.

74. - MEASUREMENTS.

Let us recall that to measure a quantity is to seek the figure which characterizes this quantity from the point of view of quantity. Everything can be measured: weight, temperature, hardness of a metal, viscosity of a liquid, etc., and even, as we shall soon see, all human tendencies or faculties of whatever order.

To measure in dowsing (as in everyday life), is to determine the figure which quantitatively characterizes the size in question: this figure can be a ratio with a unit (like the measurements of weight, pressure...) or a simple benchmark in an arbitrary scale (like temperature measurements).

To carry out the measurement, the dowser must try figures agreeing that the pendular reflex will appear when the figure tested will be that which measures the quantity to be measured. This figure only exists according to the unit or the scale chosen: the dowser must, like any man who measures (tailor, physicist, seamstress, surveyor, etc.), know perfectly the nature of the size to be measured. measure and the unit it will use.

It is for having neglected these elementary notions that dowsers have classified dowsing by measurements among the most difficult operations. This is absolutely false. We will see, in particular cases, with what levity operators embark on measurements.

The dowser will obtain a real measurement only on condition of having clearly answered these two preliminary questions:

"What am I measuring?"

"With what unit (or in what scale)?".

Therefore, the dowser who measures must think at the same time:

- a) about the subject he deals with;
- b) to the quantity to be measured for this subject;
- c) to the unit he is going to use;
- d) to the apparatus which presents the successive digits or to these successive digits which it counts by any means whatsoever;
- e) to seize the moment when the pendular reflex will occur.

Let's take a quick look at these various points:

a) The subject. - This point is the most delicate of the operation. When the dowser is sure to think exclusively about the subject he wants to study, he is sure to succeed, the question being posed without ambiguity. We will examine this point thoroughly in the Superior Course; we ask you, now, to admit this truth which we have demonstrated by thousands of experiments: any designation of the subject of research can serve for the discovery of any truth concerning it.

Thus a photograph of an individual which is only a physical description can be used for psychological or moral research, just as a letter can be used for the research of an illness; consequently, the conscientious dowser, whose duty is to neglect nothing to succeed, will always choose the best designation, the one that best evokes the subject to be studied.

However, everyone knows that the best way to evoke a person is to present an image, a photograph:

This is so true that hardened materialists, neglecting the work of our thought, have invented radiations, waves, etc., which would be emitted by photographic paper or a simple drawing! Photography is the best designation: our many students have realized this by succeeding more quickly in research in which the subject was thus defined; then, in decreasing order of ease, there is the designation by a writing, then by an object belonging to the subject, and so on.

You can use anything as long as you think about the subject you want to designate: whether the pharmacist uses the client's urine, the doctor a blood sample, etc., it is simply the effect of

occupational hazard. A coal merchant, dowser, followed a friend on the road while looking at the pendulum for a bag of coal that he himself had placed in his car: another professional deformity. A photo would have done the job much better and more cleanly.

If you cannot be given anything as an object defining the subject of the search, it is however possible if you are given the means to define this subject: everything that defines is usable, in particular the name and the address, the name and age, even the telephone number of an individual...

When the florist of Saint-Mandé gave us, to define his daughter: "Nelly CHABERT, 119, avenue de Paris, Saint-Mandé", the child was perfectly defined and we were able to be positive (§ 65).

Try searches with analogous designations, most of our students succeed in this regularly, but...start with photographs that do not claim such acrobatic attention of thought.

b) and c) Any indecision in the nature of what is measured or in the unit used renders impossible the measurement by dowsing: one could foresee it. In some cases, the accuracy of the exact nature of what is measured cannot be obtained without reflection: you will see further on the measurements of age, health index... (and, in the Superior Course, the psychological measurements) and you will make them your profit to specify so rigorously the nature of what you will have to measure.

d) The device or counting. - Some operators experience real difficulty here, especially if they have not sufficiently specified the two previous points: nature and unit. They are very embarrassed to scroll before their eyes, either with a device or mentally (in the sense: mental calculation) successive figures where they will discover the measurement sought. They find themselves exactly in the situation of the child who is beginning to count and for whom counting is still very abstract. What is the child doing? He materializes counting by counting on his fingers: in this way, he manages to clearly differentiate three from two and five from four: he counts known values with a defined unit.

It is this same embarrassment that led the dowsers of the heroic era to have small pebbles placed in their left hands or to kick the ground: a simple human way (even childish) of materializing the counting and not a method dowsing. There is no pebble method any more than there is a heel strike method: the operator counts "on pebbles" or "on kicks" because having his hands occupied (at least one), he cannot count "on his fingers".

The simple truth appears when one is not blinded by materialistic mania to the point of seeing, before a man working with all his intelligence, nothing but pebbles and feet.

When we operate outside, standing up and without a table or object that can take its place, we simply count as indicated in §§ 23 and 24 (measurements of the depth and flow of underground water). On the contrary, in all other cases, you will use a measurement dial that we have established especially for its use in dowsing.

75. - THE UNIVERSAL REPORTER.

A needle rotates, indicating at its tip a figure in the graduation of a circular sector: the operator, whose thought applies as it is said at the beginning of the previous paragraph, slowly rotates the needle by means of the button maneuvering center and looks carefully at the graduated sector.

As the measurement is intuitive and immediate, it is necessary that all the digits can be observed by the operator and that the needle suggests the measurement by its position in the sector as much as by the reading of the digit touched by its point. In short, the number must be suggested rather than read, exactly as on the face of a clock one learns the time without reading the numbers. You may have known this Parisian brasserie which replaced, on its clock, the

usual figures by BIEREBRUNE advertising letters: many customers read the time without noticing this specialty of the dial. Moreover, many modern watch or clock dials do not bear numbers.

Our long experience (which will be yours if you are willing to carry out the same tests) has led us to use a graduated sector with an opening of 120 degrees whose graduation is specially designed for quick reading, immediate awareness as that of the hour on a clock dial whose minute divisions are not looked at.

Some students wanted to perfect our dial and were quite surprised to find that "their dial no longer measured": the language was incorrect since it is not the device that measures but the man who uses the device in applying his figures to the nature of the quantity to be measured and to the chosen unit.

We call this dial "universal protractor" because the nature of the quantities to be measured is not written on it and the sector graduated from 0 to 100 can be used for all kinds of measurements.

Fig. 9. - Le rapporteur universel « Le Galt »

and, in particular, to measurements of percentages such as those which define the composition of an alloy, the degrees of functioning of an organ, the rate of visual acuity, etc. (see page 157).

76. - THE INDEX OF VITALITY.

All the dowsers have been interested in a search that seems very simple, that of the state of life or the state of death.

Let us point out that many errors are caused by a fault committed by asking the question without fixing the date on which the answer must be given: this error, which gave rise to this preposterous notion of "remanence", is unforgivable now that the truth is known about him (§ 63).

Let us also point out that no one, not even doctors, can determine exactly the state of life or death of a dying person before clinical signs, of the order of total decomposition, have appeared.

The definition of life is impossible as is that of death: we have not yet said better than Claude BERNARD and BICHAT who defined life "the set of functions that oppose death" and death "the cessation of the functions which maintained life".

This is why there are, even now, those buried alive (in ever-decreasing numbers). The question is difficult: there are a number of diagnoses of death and it was a doctor holding all the possible diplomas who gave us the only irrefutable one: total decomposition.

In practice, we call dead the one whose state is such that we do not observe in him any of the phenomena which accompany the state of life: we feel that at the moment of death something has ceased that we are unable to define and we believe we are authorized to admit that this something was both the cause of life and the cause of health. It therefore seems that this "something mysterious" is the object of research concerning both the state of life or death and the state of health.

These are the reflections that led us to seek the magnitude to be measured in order to define, by a figure, the situation of an individual in relation to life and death:

we thought that this number should provide information on the vitality of a being and the experiment realized our wish in an unexpected way since the index of vitality, measured with the pendulum in these conditions of thoughts, turned out to be simply the number of years left to live for the subject examined.

77. - THE TRUE VALUE OF THE INDEX OF VITALITY.

Several remarks are necessary superficial minds could deduce from the above a conclusion of the following kind: if I find for Mr. X.. a vitality index of 30 in 1952 that means that he will die in 1982.

This is false because health is a moving thing which improves or is destroyed according to the circumstances of individual life: a man can have, from one day to the next, a sharply rising or falling index, indicating that he is something important happened concerning his health:

Excess of table or of another nature, therapy very appropriate to his morbid state, surgical intervention, depression of psychological origin, etc..., are marked immediately and with an unsuspected precision.

Its max. - According to what we have just explained, if, for a man in perfect health, we add the years lived and the years to live, that is to say the age and the health index, we find a total that represents the maximum of human life: indeed, for all very healthy individuals the total, age plus health index is between 110 and 120. The severity of a disease is therefore measured by the difference between this normal total and the one just obtained for the patient by adding his age to the measured health index.

Logical and human. - We now see the advantage of choosing such an index to define the state of health. This choice is logical since it characterizes, in short, the result of the functions of life which is to ensure the duration of the individual: it is normal that the health index depends on age and if we find

85 for a 5 year old child,

70 for a young man of 20,

15 for a 75-year-old man,

We would say that all three of them have very good health, the same, that which allows them to live to be 90 years old.

On the other hand, the measurement of this health index is obtained under conditions of sensitivity and precision which could not be expected and which also prove the judicious choice of a truly human value.

When you receive a person whose index has risen by 2 or 3%... you can, before any confidence, assure him:

"You feel better today".

In the same way after a judiciously led cure, by measuring its index of health, a dowser will say to the patient: "You gained ten years to live or you rejuvenated ten years".

78. - EXECUTION OF THE MEASUREMENT OF A HEALTH INDEX.

We recommend taking the measurement starting with the number 100 of the universal protractor: this is logical since this number is practically never reached and it is normal for the needle to move during the measurement.

The measurement is very precise: it must be found within 1%.

In the event of a search for vitality concerning a dead person, the pendulum only turns when the needle reaches 0.

79. - THE PULSE.

No difficulty arises for the realization of this measurement which is carried out with the sector 0-100: if the pulse exceeds 100, it suffices to extend the graduated sector by adding another sector graduated from 100 to 200, or more, for example from 100 to 250.

We believe it is useful to point out to our readers that an exceptionally low pulse (50 or even a little less) does not necessarily correspond to a worrying state of anemia: some individuals live with a normally low pulse in very good health, but they are civil servants and not maneuvers of force.

We should also point out that it is a mistake to want to seek the state of life or death by measuring the pulse, which would be zero: heart failure does not mean death unless it persists for more than half a -hour. In our early days, we happened to consider as dead - but who was not dead - a patient stricken with congestion who, precisely at the time of the pulse measurement, had just had a syncope:

On the advice of the doctor who was following our tests with interest, we looked for something else and we found the health index which has never deceived us.

Moreover, the dowser does not need to bother with useless and poorly known intermediaries: it is common to hear people say of a dead person: "The heart has failed", but most of them. doctors now know that the heart is a controlled organ whose functioning is governed more by the state of the organism than by its own state. Doctor CARREL made a chicken heart "live" for twenty-one years in a bottle and this heart would perhaps still live if the preparer had not forgotten one day to renew the liquid serving as its organism.

Consequently, let us only ask the pulse for the figure which characterizes it and which will furnish us with useful information in comparison with other elements.

80. - BLOOD TENSION.

It is very easy to measure blood pressure and with an accuracy that no medical controller can guarantee. The maximum and the minimum of the blood pressure are measured: in general, the maximum is equivalent to a pressure of 12 to 15 cm of mercury and the minimum to 6 to 8.

These figures increase with age: there is hypertension when the maximum exceeds 18 and hypotension when it is less than 12.

The dowser must know the current ideas concerning arterial hypertension. First of all, we know about twenty causes of hypertension (transient or permanent); then, the Congress of Psychosomatic Medicine of 1951 classified arterial hypertension among the three morbid states relating to purely psychic therapy.

Consequently, the patient should never be told that his tension is exaggerated: the public still believes that hypertension is a very serious thing, and since emotion is one of the twenty possible causes, the patient's condition becomes more dangerous. It should be added that doctors have recognized the danger of medication which has the effect of creating a rapid drop in blood pressure.

In the event of serious hypertension, the dowsing must make known the exact measure to the doctor or to the family of the patient who will inform the doctor.

Execution of the measurement. - The universal protractor, with its sectors 0-100 and 100-250, allows to measure the minimum and the maximum of the blood pressure by reading 0-10 instead of 0-100 and 10-25 instead of 100-250. If we found a maximum greater than 25, we would use the 0-100 graduation to measure the exact figure.

81. - TEMPERATURE.

The patient's temperature can be measured very easily on a sector graduated from 34 to 42: the third sector of our universal protractor.

The dowser must always know exactly what he is measuring: he must measure the anal temperature, that indicated by the thermometer. The pendulum measurement is made to 1/10 of a degree.

Pendulum temperature measurement, which does not disturb the patient, is immediate and can be repeated frequently to closely monitor the progression or decline of a disease, especially when it comes to children in whom temperature variations are so rapid. .

82. - FIRST ELEMENTS OF A RADIESTHESIC MEDICAL CARD.

The four measurements which we have just presented to you constitute elements of a great interest which must appear on the card which the dowser establishes for the examined subject. Here is an example of the start of a form:

Mr. Jules N..., 57 years old

DATE	T	t	P	S	OBSERVATIONS
------	---	---	---	---	--------------

5/3/52	17/9	37.3	82	27	from photo
--------	------	------	----	----	------------

T: blood pressure: maximum 17, minimum 9.

t: temperature: 37.3.

P: 82 beats per minute.

S: health index.

During another visit to the patient or a search of documents, the new measurements are recorded below the old ones so as to make it possible to see, at a glance, the evolution of the disease, the return to health, the brutal effect of surgery, etc.

83. - SEX.

Contrary to what one might suppose, the search for sex is extremely delicate, whether it is a human being defined by any witness, an animal or even the embryo of an egg.

May dowsers be reassured: in everyday life, if we are to believe scholarly reviews, "the determination of the sex for each individual must be the subject of a balance sheet in which various elements listed in a work of Ombredanne who is justly authoritative". There would be five sexes interfering in such a way as to form what is commonly called the sex:

Genetic sex, assigned to each of us by the number of chromosomes with which he was originally granted.

The gonadal sex designated by the glands that equip the wearer, testicles or ovaries.

The morphological sex that jurists, since Justinian, define by the form (which is often misleading).

The functional sex which orients the spontaneous behavior of each in the use of the organs with which nature provides it.

The psychic sex which colors the whole life of the heart and the mind and not always according to the most orthodox morality.

This nomenclature which we extracted from the review SCIENCES ", of the French Association for the advancement of Sciences (N° 67, 77 year) suffices to prove to us that we will not obtain any regular result by seeking, like certain colleagues , the percentage of male and female cells constituting an individual.

You see here again the difficulty of asking the question well to know what the dowsing operation answered: do you want to know if the author of a letter is, from the point of view of civil status, male or of female sex (although for certain subjects this sex is provisional) or do you want to know if the writer is classified in the category that GOLDSMITH called in 1920 "intersexual state".

Practically, we will simply ask the question:

Male or female, male or female. To simply use our unique reflex, we will mark on a sheet of paper the two letters:

M

F

And we will agree, thinking of the individual whose sex we are looking for, that the pendulum will swing on H if he is a man or on F if he is a woman: we will avoid the complications and the errors that arise from this by defining sex like the clerk of civil status, the commissioner's brigadier and the neighborhood doctor.

84. - AGE.

It is extremely difficult to define the exact age of an individual by dowsing and this for two reasons:

- the determination of age is a determination of time for which the subconscious is very badly prepared;

- the definition of age is itself quite vague.

The first cause of error is eliminated by training in time measurements.

As for the second, it is enough to define exactly what one seeks: indeed, a human being exists before his birth and the dowser who found an error in more than nine months did not suspect that they had found the date of conception which characterizes the origin from the vital point of view of the subject studied.

One of our students took the decision to find the date of conception of the individual and subtract seven

à nine months of the age thus found (because of possible variations in the actual date of birth).

This method is usually sufficient. If you want more precision, just look for the exact date of birth, thinking about when the child was separated from the mother.

85. THE ANATOMICAL PLATES⁵.

Anatomical boards are nothing more than plans representing the human body and its different parts.

The dowser uses these boards, as it was said for any research on plan.

The transparent finder is obviously the best means of exploration to employ.

We recommend very detailed anatomical plates, including for each sex many colored plates, showing the different numbered organs, cut out and superimposed in their exact positions.

These boards obviously cannot suffice for any research to which the human organism may give rise:

The operator will have to obtain a book dealing with the anatomy in detail accompanied by a very large number of plates.

Remember that the medical dowser can render unexpected services to the doctor without being obliged to possess the slightest skill of a medical nature: he can always work on a plan and report "what is to be reported": to the doctor to take it into account.

86. - PENDULUM RADIOGRAPHY.

A very easy and too little used operation is the pendulum radiography, obtained simply by placing, on the anatomical board where something to report has been found, a good tracing paper on which a pencil point traces the outline of the affected part: it is enough for the dowser to operate as it was said in § 22 for the search for the "banks" of an underground water table.

The drawing obtained is of a precision which can be pushed as far as one wants: the precision then becomes a question of scale of the board which can be replaced by a simple sketch.

The "radiography" thus obtained has the advantage of presenting the lesion, the tumour, the fracture, etc. in such a way that nothing hinders its study: there are no superimpositions and blurs that complicate the interpretation of x-rays.

Moreover, as the sensitivity of the dowser is so to speak infinite, capable of detecting lesions or tumors at the origin, the "pendulum radiography" can inform the doctor long before the photograph is usable.

87. - AN EXAMPLE.

We give below an example drawn from the collection of a known dowser who, without having specialized in medical dowsing, responds to requests made to him by or for a doctor.

A lady came to consult him for her niece, a six-month-old child whose bizarre behavior was causing serious concern to the family and insoluble problems to the four doctors consulted.

Here is the answer of the dowser which, dated and signed, as it should be, was given in triplicate to the consultant (for her, for the mother and for the doctors)

"N..., March 30, 1951.

Mrs,

"I studied, at your request, little Marcelle S...:

I am sending you, attached, the sketch obtained from the anatomical plates by seeking on the pendulum the organs or parts of the body deserving the doctor's attention. Two points are to be noted:

" 1. Cerebellum: in red the offending portion.

" 2. Duodenum: in red the offending portion.

" I purposely refrain from commenting, merely pointing out that the...brain thing is critical to this child.

You can communicate this information to the doctors who take care of your niece: it is moreover for this purpose, to try to be useful, that I undertook this study. On the other hand, I think I can affirm that a very careful X-ray will show what I have just indicated.

" Please accept..

" Signature and address"

Each copy was accompanied by two tracings established as we have just explained.

Here is the technical information on this operation

Designation: name, age and address of the little girl (the aunt had no photo).

Research on the general board first, then on that of the brain and that of the stomach with the transparent researcher.

Relative importance of the two identified lesions quantified with the universal protractor.

You must all be able to carry out such a search, at least with the designation of the patient by a photograph.

Let us add that, in our opinion, nobody can criticize the principle of such a collaboration between medicine and dowsing. The doctors took into account the research concerning little Marcelle but the X-ray did not reveal until four months later the... thing indicated by the dowsing, which greatly surprised Professor C... of Paris, the one of the four doctors consulted whose intuition had been correct but without clinical verification.

LESSON EIGHT

OTHER ADAPTATIONS OF OUR METHOD

You know how to search on the spot or on the map for water, minerals, pipes, lost objects, the diagnosis of an illness with the elements constituting the patient's medical file, etc.

Our method which is established according to the nature of the dowsing, means of knowledge, adapts very easily to any branch of knowledge: we advise you, each time it is possible, to proceed by measurements: you will obtain thus without fatigue a more tense attention and the result will be more precise, which is never a disadvantage. To illustrate this advice, here is a fun example:

A comrade receiving a letter from an unknown young girl asked us to tell him if this young girl was tall or short. Thinking of the signatory of the letter, we looked to the universal protractor for the number of centimeters of her height above one meter: we measured 61 and announced: "She has m. 61". The comrade was bewildered: "You even tell me his height". Reflect and when you will have understood the illogicality of this "same", you will be fixed on what we call a dowsing method.

Although you are able to adapt the method to any case, we will go over some common questions in order to give you, along the way, some practical advice from a long experience.

88. - VETERINARY MEDICINE.

The same principles are applicable to animals as well as to humans: it is not necessary to be a veterinarian to define the affected organs or the deficient functions.

For the dowser, the animal race offers the great advantage of not being gifted with speech (sick and his entourage): the dowsing work therefore gains in calm and neutrality.

89. - FOOD.

Here is an important domain where the action of the dowser is exercised daily. Here again, the universal protractor provides the solution of almost all problems: choice of food for humans or animals, dosage, search for vitamins, etc.

But beware! Two pitfalls are to be avoided:

- 1) The absence of neutrality, which may make you find hay that looks unattractive when the animals would be perfectly fine with it;
- 2) The defect of certain dowsers who slide towards mania and control (!) at all times their food or that of their familiars.

It is to be feared that by carrying out useless operations (hare stew for a stomach disease, sweet desserts for a diabetic, pudding for a liverwort, etc.) we will manage to obtain pendular movements due to normal knowledge and preliminary: in this case, one gets used to movements other than the reflex movements associated with the truth sought and which destroy in the operator this conditioning of the reflex which is the whole of dowsing: one therefore risks losing all safety in one's research .

90. - CHOICE OF A SITUATION. BUSINESS COMPARISON.

Think of the advantage that there would be for the consultant to choose a certain situation or to enter into such a business: quantify this advantage to the universal reporter and he will compare himself.

It is obvious that you can only do this operation validly if you are unaware of everything about each of the situations or cases to be compared: the neutrality of the dowser - let us remember it again - allows no exception.

Under these conditions, you can do this research for yourself, of course.

91. - CHOICE OF A COLLABORATOR.

We describe in "KNOWLEDGE BY RADIESTHESIA" (the last 3 chapters of Volume 1: Psychological Dowsing) a scientific, complete and safe method allowing to judge and compare men but while waiting to know these exceptional processes, you can measure, for each of the candidates, qualities such as:

Professional skills, honesty, order.

The precision of your measurements will be the one with which you have defined the measured quality.

92. - HUNTING AND FISHING.

It is easy to find game lodges on a map, and we have known French professionals wiring English hunters with indications of this kind to ensure the success of fox hunts. It is only necessary to take into account a remark made by the majority of the dowsers, who, like the commandant of La Bastille, devoted themselves to this research: the dowsing operation must be carried out very quickly because the game feels that the man searches for it and, in fear, moves if the feeling lasts long enough.

Much has been said about this fact which has nevertheless been verified several times: it should not surprise you, you who know that the thought of the dowser goes to the place where the truth can be known. We have said it: any dowsing prospection is a distance prospection: whether it is 5 centimeters, 5 meters, 5 kilometers or 500 kilometers, that does not change the matter.

93. - HARMFUL ATMOSPHERE.

We are dealing here with a problem which has caused a lot of ink to flow and which has given rise to the most odious charlatanism: shameless traders have been able to sell neutralizers or various devices without objective value to people without culture frightened by the waves of cancer. er and the radiations of the bacillus of Koch... It was possible to sell twists of metal wire under the pedantic name of solenoids which were to prevent the father from coughing, the mother from dreaming and the son from forgetting his lessons, simply by placing it under their bed and no one among these poor dupes thought that his box spring was already... a field of solenoids!

What should we think of harmful atmospheres?

As in all things, it is essential to define what we are talking about: we have not done so and, despite the volumes and articles dealing with this subject, the question has never been seriously studied.

These are obviously local conditions which are pernicious for human life and for the life of animals or for the life of plants. However, human beings are very different from each other, to the point that the conditions of a harmfulness of a general nature do not arise from a summary investigation: one cannot

decree, following a radiesthesic operation, that all men living in a certain place will be subject to illnesses or even to characteristic illnesses.

The various climates of France, for example, are excellent or harmful according to individuals and times. Is the climate of Berck-Plage, which cures bone tuberculosis, harmful because a nervous child or a pulmonary tuberculosis patient cannot adapt?

Will we say that the atmosphere of almost total isolation is good or bad? It will make the man of action and the frivolous woman die of boredom, but it will allow the writer to create in full cerebral activity.

The dowzers in general and their usual clientele understand, by harmful atmosphere, the result of a mysterious action of the basement and one can see this frightening thing: a pendulist seeks the action of the basement and, as soon as his pendulum turns, it announces a harmful atmosphere: it draws lines, grids, zones and it prohibits health or even life at points which can only be distinguished by a gas pipe, a water pipe or a flaw without interest.

In this area as in others, you have to know what you are looking for to know what you find.

There are certainly areas and lines of land on which the life of a human being is subjected to significant actions, but it is necessary to take into account the beings who will be subjected to them, as Lieutenant-Colonel ALLOUCHERY perfectly observed in his solution of a dowsing contest on harmful atmospheres that we organized in 1951. Having discovered a fault under the house to be studied, he specified: "Can have a small action on people in poor health, favorable for certain nervous affections, unfavorable for others".

This is very sensible: people, like animals, react differently to same material living conditions: Alsations know very well that cat houses are not stork houses.

But that is not the whole point: man has more complex faculties than animals and his reaction to various environments will be much more complex. The psychological is called upon to play a role that can be decisive: we will therefore treat this question completely in "Psychological Dowsing".

94. - JUDICIAL RADIESTHESIA .

The number of dowzers who collaborate with the police in the search for the perpetrators of crimes or misdemeanors is greater than the public imagines: this collaboration is generally very discreet and it must be encouraged since the police and the magistrates can only to gain there: an error would involve them well on a false track but at the time when the dowser is consulted, the police force already started the series of its "unfruitful searches".

The subject being extremely vast, we will limit ourselves to a few cases which will serve as an example for other cases.

Case where the criminal is necessarily among a group of known individuals

The following method gives us complete satisfaction: we ask that we be given a list of these individuals (in general the first name is enough) and we measure the responsibility of each one with the universal reporter: and that's it.

This process is very practical because if you have found Michel 95% and Gustave 15%, you announce to the dumbfounded police: "It was Michel who did the trick with Gustave as an accomplice".

Note N° 1. - This measurement process involves such sensitivity that it provides you with all the indications allowing you to establish responsibilities and force explanations from those responsible.

In a recent case (assassination) we found the murderer and his accomplice but, for a third individual, the universal reporter accused 5% of responsibility. We announced that the named X,.. must have, by an action or an omission, helped to carry out the crime without being guilty in the precise sense of the word: who is X...? The master of the house replied very boldly:

" It's me indeed, I heard a noise around 1 am and, obviously, I should have gone to see "...

You judge here of the importance of the way in which the question is posed by the dowser; we did not seek guilt but responsibility which is more general. This distinction and the richness of the fruits which it brings back can give you an outline of what we have to say to you in " The psychological Dowsing ".

Note No 2. - In order to ensure maximum neutrality and to provide a beginning of verification of operations, we always ask interested parties to add to the complete list of individuals who are suspected or simply present at the scene of the crime, several names of people certainly foreign to the case or even imaginary characters: for these added names the universal reporter must obviously indicate 0.

Under these conditions, the last subject examined can perfectly be an imaginary one (the order of the list is arbitrary, the imaginary ones being mixed with the real ones) and the dowser is not tempted by the known suggestion: "And if he only one remains, it is surely this one ".

Indeed the criminal is perhaps not in the list which was given to you and there is perhaps no criminal.

In 1950, a farmer's wife came to ask us to look for the miserable arsonist who had set fire à one of her haystacks: she assured that this misdeed came after numerous thefts and sabotage and she was outraged at this last malevolence. As she could give the list of all the people present on the day of the fire, we looked for the arsonist and we did not find the criminal: surprise of the farmer's wife in front of whom we looked for the person in charge and we found a farm worker who confessed to having smoked near the millstone after having stolen some eggs which he had seen nearby.

It is since this case that we are looking for those responsible.

General case

We cannot give precise directives, the cases being very varied: but if one faithfully follows the advice which we have given during this work, one quickly manages to know how to ask the question in such a way as to reconcile the dowsing technique with a problem whose solution will bring light.

If it is a theft, the search is done without difficulty as soon as the stolen object has been defined exactly: then, its discovery makes the thief known in a more or less direct way.

But when the dowser has located the product of the theft, the search is not determined for the victim. Searches of an individual reported as a thief or concealer by a dowser are almost always impossible and that is why many colleagues refuse to undertake operations of this kind: however, one never knows, before doing the research, what will be the continuation and checks, unforeseen overlappings can bring the police force to use the solution radiesthesic.

We remember a search for a stolen jewel for which the thief was Jules: the jewel was located at the pendulum in an apartment occupied by a certain Lola; or someone says: "Lola is Jules' mistress". This suffices as verification.

Advice to the judicial dowser

We especially draw your attention to the delicate nature of criminal investigations: it is very difficult to prevent gossip, presentation of the most probable versions, disinterested advice, discoveries by a colleague, moral guarantees concerning certain individuals, suspicions for others, etc

The dowser who agrees to take care of a criminal case must police himself: "Don't tell me nothing: answer only my questions". Then he questions, not with the intention of forming an opinion, but in order to determine the questions that he will ask himself in order to solve them by dowsing.

95. ARCHAEOLOGICAL RESEARCH.

There is a field of human knowledge where dowsing is little used and it is regrettable, because it would render services of the first order by saving time and saving considerable costs: it is that of archaeology.

A dowser to whom we would ask precise questions concerning fossils to be sought, vestiges of civilization, prehistoric caves, etc., should regularly provide answers of the highest interest: our method adapts to it as to other fields with the same output. provided that the same principles are respected. In particular, it is essential that the operator be informed exactly about what he must look for. An example will make it clear where the difficulty of this kind of research lies:

In 1941, at Oflag IV D, I found one of my students, Captain Le V..., in conversation with a young archaeologist who suddenly asked him:

"Will you look for me on this map the prehistoric caves?"

Le V..., an excellent operator, accepted immediately and we, the archaeologist and I, saw his tracing paper (transparent researcher) slide over the map from end to end while the pendulum continued its small oscillations imperturbably. I looked at my student smiling.

" You smile! he told me. Do you know why this is wrong? - I suspect so, I answered; think about it and... it will work".

After a few moments, Le V... asked his comrade: "What is, really, a prehistoric cave?"

"Bravo! I said immediately. Now they are ours".

The archaeologist explained that a prehistoric cave is not necessarily a 20th century cave: since men have occupied it, leaving there objects or interesting traces of their lives, the cave has been able to become clogged and cleared may be needed before any finds can be made.

The V... restarted the operation which could appear identical to the first one but differed from it completely because, this time, his thought was able to go down from a general knowledge to a particular knowledge: the reflex associated with this particular knowledge occurred five times. Five sites were marked on the plan and the archaeologist exclaimed with joy:

"Wonderful! Of these five points, there are four that I know of, that I have explored: the fifth is therefore also good: it is a real discovery that you facilitate for me and from here, in Silesia, thousands of kilometers away...".

We cannot study completely in this work the technique of the radiesthetic research of ores or other mineral compounds: here are the essential points:

1.- The operation is carried out on a plan by successively using various cards; generally we start with a large scale map on which the transparent finder completely covers the area to be explored and we end with the cadastral plan or even with a road map.

2.- The difficulty of these searches is due to the fact that the dowser finds as easily traces of ore without interest for the mining company as the unexpected deposit which will ensure the complete success of the company: it is therefore necessary to seek not "the iron ore" but "an iron ore deposit justifying exploitation". The size of the deposit can be quantified in relation to a known deposit.

3.- The information to be provided to future operators includes, together with the site map of the discovered deposit, indications concerning its depth and thickness. The dowser must thus carry out measurements in sufficient number so that the basement is perfectly known; the best method consists in drawing on the site plan several points in a straight line ABCD E... and giving by a table for each of these points the depth of the ore and the lower limit of the deposit, for example A of 12 m . at 60 m, B of 15 m. 70 m...In this way, the mining company has a true "ABCD section of the land".

We have described in detail in Issue No 42 of the Review:

Initiation et Science "our search for uranium in the Vosges, January 1957: the reader can usefully refer to it (see page 161).

96. - MILITARY ART.

The dowsing finds numerous applications in the various problems of knowledge which the art of the war poses. Indeed, secrecy is essential in any military operation and knowledge of enemy devices or simply of a few details of these devices can significantly strengthen the position of a belligerent.

There is no doubt that the German army used dowsing to search for Allied convoys and their attack by its submarines. In certain French prison camps, German officers were seen handling the pendulum and the Gestapo had received the order to seize all the pendulums and all the rods possessed by the prisoners: we were thus confiscated about fifty pendulums which were replaced immediately by others, generally melted with the pewter of tubes for oil or watercolor paint.

At Oflag IV D, a German captain told us in 1942:

" Dig no more underground passages: you will no longer escape by this means".

Ourselves, when we were prisoners in Oflag VI D in Münster, we followed, with the pendulum, the progress of the English or American planes coming to bombard the Ruhr and our "course of route" indicated to us if the alert trumpeted by the Kommandantur should or should not worry us. Finally, we kept up to date the map of the German posts guarding the border in the vicinity of Metz in order to inform the comrades whose escape was planned through this region: we had found some

something rather funny which was confirmed by an unfortunate comrade, taken back to France: on Sunday, the Germans suppressed one post out of two near Saint-Avoid. (We had made progress in dowsing since our conference in July 1940).

The uses of dowsing in times of war are countless; note:

- For the artillery: the search for the points of fall and the adjustment of the shots;
- For aviation: all route checks and searches in the event of forced landings;
- For the troops in cantonment: the search for drinking water in the event that the wells and springs are infected by the enemy;
- For defense against aircraft and for the navy: spotting enemy formations.

LESSON NINTH

THE LATEST TIPS

97. - THE MENTALITY OF THE RADIESTHESIST.

We have explained to you our method which, as you have seen, is absolutely general: we have repeated the same formulas for each operation at the risk of seeming tedious, but you must realize that we want to achieve certainty of the results by standardization complete. When you have become accustomed to the four phases concerning extremely varied operations, you will do as we do: you will no longer think about them and automatically your thought will do the usual work as automatically you close the door on leaving your home.

But you will never be able to dispense with asking the question with absolute precision.

Little by little you will acquire an assurance which will astonish your relatives but which you will accept without thinking about it and it will be good to reflect on the mentality of the dowser, that is to say on his psychological behavior towards his fellow men. .

It has been said that the dowser could only operate validly in a sympathetic or at least neutral environment: this is not exact. It is possible to succeed in a stormy, even hostile assembly, provided that:

1° have a clear method in which everything is rational, understandable and justified; it is now your case;

2° Be absolutely neutral, to the point of making fun of what the result will be (true or false), what people think of you, possible consequences, etc. This is very difficult, especially for a professional, a professor, a trader in dowsing and, in general, they do not risk it.

It is conceivable that, the dowsing discovery being a fact of the subconscious, it will not occur if the operator blocks his thought on very conscious considerations of lost reputation, biting mockery, declining turnover, etc.

In short, you have to achieve a detachment such that you always operate as if you were alone in the world, working for yourself with the aim of disinterested study: besides, every artist is there and you can compare the works of a painter between them, those he painted for work, those he made to order and finally those that were created for a competition.

Glues

Beware of the glue that is put to you by people who want to catch you at fault: you will get off to your credit if you get into the habit of not believing anything you are told or what people are looking for. to suggest to you. Notice that the regular exercise of dowsing leads you to such skepticism:

- a woman who thinks she has cancer in her throat simply suffers from a stomach ulcer healed in eight days;
- When a woman says she lost a piece of jewelry on the train, at a distant wedding, etc., in 95% of cases this piece of jewelry is found in her room;
- police affairs also make you very neutral in the face of the most vehement assertions.

After a long conference that we gave in 1951 in a neighboring capital, we did as usual a certain number of dowsing research on photos (physiological and psychological): the room only became frankly sympathetic after the incident. next:

A very old gentleman, with a white beard, surrounded by a compact group came to the podium and asked us:

" Can you tell from the photo if a person is dead or alive? - Perfectly, I

announced it in the conference.

- Then answer me for this child ".

He presented us with the photo of a child of about eighteen months: after a few measurements that you can guess and... a check, we gave him the photo and said to him:

Take your photo again: no need to tell you if you're alive but to stay alive for a long time take care of your liver which is very sick".

The humanity of the dowser

Because of what he can know when it is asked of him and even when it is not asked of him, the dowser worthy of this noble function is bound to a certain reserve. All is not good to say: we do not need to insist.

In particular, for a patient, you should never give anyone other than the doctor the complete list of what you have found, and this for two reasons:

a) in order to heal, the patient always needs to believe in healing: he must know the minimum about his condition;

b) Among the deficiencies observed, one is essential and its treatment, by improving the general condition, often causes the secondary deficiencies to disappear, of which it was therefore useless to speak. The whole man is ill:

it must not be forgotten.

However, we have in our hands a diagnosis made by a dowsing doctor and given to the consultant who learned with amazement that he had 27 illnesses: furious then joyful at such resistance, he did not cure anything and is doing very well.

98. - THE REPETITION OF OPERATIONS.

We have often been asked the question: "How many times do we have to do this experiment?".

If you have well understood the nature of the radiesthesic operation, you can answer this question yourself.

Let us distinguish two cases: that of the operation which one starts again with an aim of checking and that of different operations but of the same kind which one makes "in series" to acquire a good "training".

a) The operation restarted for verification

It is absolutely contrary to common sense to repeat a dowsing operation: indeed, you must undertake a search with a pendulum or a rod in the best possible conditions, so why start over? If you operate under bad conditions (fatigue, lack of preparation, distraction from the outside, preconceived idea, etc.) you are committing a big mistake which can stop your success for the future by lack of confidence in yourself and in dowsing.

The first operation must be the only one and it must be made to be the only one.

Moreover, our great experience of competitions has shown us that, when competitors hold à send several solutions to the problem posed, if there is an exact answer it is the one that corresponds to the first operation.

This is easy to justify: after the first operation the dowser cannot know the expectation completely neutral and his attention oscillates between the result already found and another: there are comparisons in his mind between these two solutions and the first can just as well be repeated as bad as rejected as good.

If you find the same result three times in a row, do not believe that it is verified; you may have fallen back into the rut of the first operation twice. You are not a manometer, an electroscope, a gas meter, etc., nor another stupid machine which after having given an indication is exactly as neutral and inert as before... You agree with us that the man is endowed with memory and the man who has made a measurement is different from the one who has not made it.

If you want a verification of your operation, have it redone by a colleague to whom, of course, you will not tell what you have found.

The search for the average

Some dowsers have put forward the idea of seeking, for a dowsing problem, several successive solutions and of making the average. It is difficult to find a more stupid reasoning: indeed, if you look for an individual three times in a row on a map and if you find Bordeaux, Calais and Brest, you are not going to announce that he is in... Tours!

Realize that out of three different solutions to the same problem, only one at most can be the correct one and that, consequently, the average of these solutions is always wrong: some minds may object that physics is teeming with examples of several measurements carried out with the aim of taking the average which will be the best possible measurement: we will point out that all the measurements of physics are exact, differing only by variations of little importance which one can suppose that they are distribute equally on either side of the precise measure (in the case of many measures). This is not at all the case in dowsing where the operator does something other than read a graduation and where, by the effect of the mistakes made, he can find 4 meters as well as 50 meters or 300 meters for the depth of a body of water.

b) Serial operations

Here is a very important point on which you must be informed definitively. We repeated voluntarily in this elementary course that the radiesthetic operation requires on behalf of that which carries out it a perfect attention: this attention is at the same time active in that it poses the problem, chooses the method and applies to the object of research and passive in the sense that, within the framework thus established, it awaits the manifestation of the solution. If you analyze what happens in the mind of the operator during the four stages of the operation, you will realize that there reigns an exceptional activity and tension (see § 74 again): this tension is the same than that of the thought which attaches itself to rediscovering a memory which slips away, it is the effort of

remembrance itself which cannot be sustained for long nor repeated several times in succession. Try to get a child who knows it by heart to recite a fable from LA FONTAINE ten times in a row: you can expect accelerated stammering. Similarly, if you have a musician play a series of similar pieces: to play them and to listen to them you need to have a special culture that makes you judge the differences that escape ordinary mortals. There is a risk, by doing series of searches of the same kind, of tiring the attention to the point of preventing the association of the reflex with the solution sought and the movement is done anyhow, out of weariness, just like a schoolboy tired by cascading questions to which he cannot immediately find the answers, says anything to "get it over".

Consequently the dowzers who know their trade cannot agree to engage in series of experiments supposedly intended to prove the existence of the dowsing by more frequent successes than would indicate it the calculation of the probabilities those which propose to such "demonstrations" simply prove that with dowsing they also ignore man and the calculation of probabilities itself.

The operator who searches for the seventh time for a coin in a book, for the ninth time for the jack of hearts in a certain number of cards, cannot pay the same attention to it as at the first time: attention demands for apply conditions of spontaneity, improvisation, surprise which cannot be maintained during a series of trials: we have read in a brochure (La Sourcellerie, Dr JARRICOT, p. 32)

" The distribution of successes per day shows on the first attempt of each day correct results in 100% of cases, on the second and third attempts of the same day a clear decrease in successes (71.4% on average): for the fourth daily attempt a drop in results of up to 42.3%, a result lower than mere chance data..."

This quotation illustrates what we have just said: yet doctor JARRICOT proposed recently a series of experiments to study the dowsing fact: one unfortunately found dowzers to deliver themselves to these anti-human operations which were, as we had announced it in advance, only a mumble without interest.

We ask you to consider each radiesthetic operation that you will undertake as a unique operation which requires on your part the bringing into play of all your intellectual faculties for the preparation and of your subconscious faculties for the revelation by conditioned reflex: consequently do it as seriously as if you sat down at your table to compose a masterpiece and then rested by changing your occupation.

99. - HOW TO MAKE PROGRESS IN RADIESTHESIA?

Do not believe that by operating very often you will acquire training which will automatically ensure you an increasing percentage of successes: this is no more true in dowsing than in the other arts.

Each art comprises a part knowledge and a technical part: the dowsing being a means of knowledge it is not surprising that one makes more progress there by knowing well what one does rather than by artifices of technique.

This is why we simplified the technique to the extreme (single method, single reflex, maximally standardized operation, easy-to-use material) which allowed us to see very clearly the truly human part of the operation.

So take advantage of this development which has taken a long time: each of your operations must be clear work for you, well prepared, where you see the importance of each gesture and each thought.

Doing what is essential and avoiding all that is useless, here is the secret of particular success and of progress in general: it is not by accumulating bad habits that one becomes a high-class practitioner.

From time to time, do an experiment for yourself, thinking deeply before doing it and after doing it, discussing every detail, looking for the best way to operate, phase by phase: whatever the result you will reap a huge profit.

But the operation which will bring you the most from the point of view of progress is the failed operation in which this discussion with yourself will have made you discover a fault on your part. This day will be for you a day of great victory, that which changes your class better than all the advancements and all the degrees. This is a mistake you will never make again Think of the joy of the motorist who could say to himself: "Never will I have more ignition failures" and then after a few other experiences would say the same thing for the tires, etc

You must think: but then if any error comes from a fault and if I do not commit any more fault I can become an infallible dowser! And you smile at the closeness of these last words here is the truth which earned us much mockery until the moment when the facts proved us right:

The four stages of the dowsing operation are naturally grouped into two parts: the first three are the work of thought, therefore of the conscious and the last is that of the subconscious.

The work of the subconscious is the very exercise of an animal faculty (more general than human), that which allows the conditioned reflex: now this reflex is marvelously infallible. You know the safety of the reflexes acquired by the motorist, by a trained animal... The error does not come from the conditioned reflex of the radiesthesist operator.

The work of thought, on the other hand, is very open to criticism:

we have seen colleagues embark on ill-prepared research where they could not succeed. Only in the way of asking the question one can find errors in power: a friend dowser however confirmed sought the residence of a young girl on a list of French departments and found it in the last of his list whereas it was in America, an error corresponding to a fault that we have foreseen in § 62 (you had to take a planisphere).

You thus arrive at the point where we were in 1941 when we defined the error in dowsing as consequence of a fault of the operator and when we, consequently, proclaimed that the dowsing was infallible.

So don't think it unreasonable to aspire to 100% success: you will achieve it in the branch where you are able to think without mistakes.

In this branch you will be able to guarantee your discoveries for the greatest good of your consultants and for your greatest satisfaction.

As for the other branches, your progress will require on your part an appropriate development of culture which will have nothing to do with dowsing.

Before leaving you, we tell you about a visit we made, in 1946, to a young woman following a conference we had given on psychological dowsing.

" I am doing well at the pendulum in underground research but what I would like to do are psychological studies as you have explained to us and read some of them. This must be exciting to penetrate to the depths of souls, not to be deceived by appearances..."

During the flow of words, we had the pendulum in our hands and, discreetly, took some measures: we then answered the: What should I do?

" Do you have a pendulum,

madam?" Yes, I have the

pendulum....

- Well! Put it in the drawer and...do psychology...eight hours a day...for...a year".

This true story is not understood by everyone; we hope it presents no mystery to you. Dowsing is a good girl who only asks to serve: it is still necessary to know how to ask her what is expected of her.

Maurice Le Gall

The “LE GALL” pendulum

The pendulum “LE GALL” is a bimetallic pendulum whose all the characteristics were studied in order to obtain the speed, the sensitivity and the safety of the dowsing operators.

SPEED AND SENSITIVITY.

- Every operator who has tried this pendulum has been amazed at how quickly they get the pendulum reflex. This rapidity is an essential condition for success, because waiting for the reflex is a critical period, during which suggestions of all kinds risk giving rise to a false solution.

The speed of the LE GALL pendulum is largely due to its perfect balance resulting from its shape and the use of light metal in its central and lower part. Under these conditions, the very weak impulses which cause the movement of the pendulum apply immediately to all its mass which then moves in the minimum of time.

SAFETY.

- If speed is a factor of precision for the dowsing operation, there are, however, still others: the balancing of a pendulum does not only require, in fact, a high center of gravity but also the distribution regularity of the masses around this center. The LE GALL pendulum, which is inscribed in a square, whose shape is hemispherical, responds perfectly to these mechanical balancing conditions.

This second balancing condition (distribution of masses around the center of gravity) is as important as the first (high position of the center of gravity). Thanks to its high-precision manufacture and its scientifically established characteristics, the LE GALL pendulum takes only perfectly clean movements and cannot, like most unbalanced pendulums, move in a way that the dowser has difficulty in recognizing. These false movements - impossible with the pendulum that we present - have the effect of disturbing the operator who, believing to see the reflex begin, is brought to support it unconsciously, thus removing any safety with the radiesthetic operation. The LE GALL pendulum does not know these parasitic movements, and when it announces a solution by its reflex movement, this one is clear, sure, without these burrs analogous to the stammering in the language. It is following fruitful tests that a well-known professional dowser told us: “The LE GALL pendulum is a pendulum which does not stutter...”.

THE WEIGHT OF THE PENDULUM.

- The LE GALL pendulum has been established so that it is the best in all dowsing operations and its weight of 40 grams is justified by the following two reasons:

Inside, in a building, during each operation, the dowser must look at a certain number of objects: various witnesses, measuring devices, documents, etc. If he operates with a light pendulum, he is forced to observe it, too, in order to see the direction of its movement. The 40 grams of the LE GALL pendulum spare him this concern, because we feel “his movement, hence an indisputable advantage which benefits the attention of the dowser and, consequently, his success. On the other hand, experience shows that it is useless to exceed the weight of 40 grams which would make the pendulum tiring and less sensitive.

Outside another question still arises: that of the action of the wind. The LE GALL pendulum, thanks to its weight and its squat shape, does not catch the wind and allows it to operate in all weathers.

A UNIQUE PENDULUM:

The very successful operators have long recognized that, if it is essential to rely on a single reflex, it is also necessary to use only one pendulum, in order to obtain a true automatism of the reflex and of the sensitivity. . The language of this unique pendulum thus becomes the dowser's instrument of expression.

The LE GALL pendulum is the one that best meets all needs and applies to all cases that may arise. It should be held, as a rule, at a length of chain equal to 5 centimeters.

Le pendule bimétallique « Le Gall ».
Fig. 10

LE GALL GRADUATE SECTOR

A large number of dowzers have thought of using as a reflex the direction taken by the pendulum when it passes from gyration to oscillation: by placing under the pendulum A GRADED SECTOR, that is to say a portion of a circle limited by two rays and graduated like an ordinary protractor, the direction taken by the pendulum is marked by the graduation.

To carry out a measurement, it is enough, after having placed the pendulum above the center of the sector, to agree that “the measurement will be the figure of the graduation towards which the pendulum will move while oscillating”.

Operators who have employed this technique have encountered a few difficulties:

a) Common sense first rejects any sector having an aperture greater than 180° for the good reason that the pendulum, oscillating on a diameter, does not indicate one extremity more than the other: the same plane of oscillation can define as well 300° as 210°. The graduated sector must even be less open than 180° because the 0 and the maximum would correspond to the same direction.

On the other hand, so that the graduated sector is well SEEN by the dowser, as we specified it in § 74, the opening of 120° is certainly the best.

b) The graduated sector must be very small (fragment of a circle with a small radius), since the pendulum oscillates by deviating from the vertical by only a few centimeters.

c) In order for the oscillation to be clearly marked on the graduated sector, the pendulum must end with a point: even in this case reading is not easy because the underside of the pendulum is not clearly visible.

In order to eliminate the disadvantages due to the technique exposed above, we have created the graduated sector of which the figure below gives a detailed explanation.

Sector opening is 120°; the extreme radii graduated 0 and 100 delimit it perfectly thanks to a design whose aesthetic character is only a consequence;

Fig. 11. — Secteur gradué « Le Gall »

The unevenness of the radii from 10 to 90 allows an extremely clear graduation despite the small dimensions of the sector. Finally, A GLASS shows the operator the underside of the pendulum, the tip of which, completely visible, comes to define by oscillating a precise direction which amounts to within 1% with a little practice (see: intuitive measurement § 74).

INSTRUCTIONS FOR USE OF THE GRADUATE SECTOR.

When you have correctly posed the question which must have a number as an answer:

Place the pendulum above the graduated sector so that the image of its tip, in the mirror, is at the center of the sector;

Give the pendulum a rotational movement of very small radius (a few millimeters).

So, thinking intently about what you are measuring, wait for the pendulum to swing and read the measurement as soon as the tip of the pendulum (seen in the mirror) touches the graduated rays. NOTE: We have performed, with this graduated sector on ice, thousands of dowsing measurements (age, health index, weight, pulse, blood pressure, temperature, water depth and flow, various percentages, psychological faculties, etc.), however we abandoned it in favor of the UNIVERSAL PROTRACTOR to which we give exceptional ease of use by juxtaposing three graduated sectors, specially adapted to the needs of medical dowsing. On the other hand, the graduated sector on ice imposes the immobilization of the operator's head: in fact, a displacement of his eyes would modify the apparent position of the tip of the pendulum with respect to the center of the sector.

When the dowser waits for the transformation of the waiting gyration or oscillation which measures, he is completely motionless, manipulating nothing with his left hand:

his attention is exercised with the maximum concentration and neutrality: this has been recognized by several professional dowsers who were kind enough to congratulate us for the development of this little "magic instrument" of extraordinary efficiency especially for training of the dowser and for the control of This training.

THE TIME CONSTANT.

Our graduated sector gives you a simple means of knowing the time necessary for the realization of the reflex that you expect in the third phase of the radiesthesic operation (§ 6).

We recommend the following experience: when you are ready to measure on the graduated sector, ask an assistant to tell you a number between 0 and 100 and look at the sector while waiting for the pendulum to indicate the announced number.

If your assistant has a chronograph that he starts by announcing the number and stops when you say "Top" to him as soon as the pendulum indicates the announced number, he measures exactly the time you need to get a reflex corresponding to a known number: this is your time constant.

As you will need at least equal time for a measurement of unknown value, you can also have a precise idea of your training and then check the progress you will have made by judiciously conducted exercises. You will verify the influence of the correct holding of the pendulum (§ 5), of the relaxation of the operation, of the freedom of your thought at the time of the exercise and you will be able to indulge in all kinds of experiments, for example check that your pendulum is, without a doubt, the one that gives you the minimum time constant.

IMPORTANCE OF THE TIME CONSTANT.

This importance escaped all those who wanted to study the dowsing operation and yet it is essential.

If you find that it takes you 3 seconds for your pendulum to indicate the number 37 or 56 which has been announced to you, you must deduce that 4 or 5 seconds will be necessary for you to obtain a dowsing measurement, i.e. say of unknown value. Under these conditions, you must conclude that, to work on a plan by exploration with a transparent finder, to work on the ground by advancing your right foot, in short, for any operation involving a

movement, you should stay still for 5 seconds on each point. Similarly, for a measurement with the universal protractor, you should stay 5 seconds on each number: if you move your finder, your foot or the needle of the universal protractor faster, you will find a wrong answer, all the more wrong as you work faster.

Now, it is necessary to work quickly to avoid the fatigue of the attention, the fatigue of the body and the appearance of the suggestions of the imagination.

The dowser with a strong time constant is therefore this dowser with "percentages of successes" which dishonors the profession and discredits it in the eyes of the learned world: in medical dowsing he will find a disease of the heart or a disease of the intestine for a disease of the stomach according to whether he will explore from the feet to the head or from the head at the feet.

The excessively strong time constant is responsible for all the errors committed by good dowsers as soon as it is no longer a question of motionless objects studied by a motionless operator: this is why "masters" seek to explain their failures by research on plan by absurd theories involving physical agents, occult influences, superstitions, etc.

You have to manage to get the pendular reflex in one second (two seconds being one maximum to be reduced); do and redo the test of your time constant several times: it will inform you about your behavior in the physiological part of the radiesthetic operation.

This measurement of your time constant will prove to you that any progress in the speed of the operation brings you closer to the infallibility which is the goal of any serious dowser.

We put a pendulum in the hand of a person who had no notion of dowsing and we made him do the experiment which consists in waiting for the pendulum to indicate on the graduated sector the number that we announced to him. This person was greatly surprised when she noticed the result: without her doing anything consciously, the pendulum held by her hand indicated the announced figure.

We hope that a very large number of individuals engage in this experience and then reflect on this bizarre phenomenon which reveals to them a part, however weak, of the dowsing fact. After these reflections they will no longer be able to doubt the existence of the conditioned reflex which is the basis of our art and without which it would only be a divinatory art without method and without security.

In summary, our graduated sector has become, after its existence as an accessory for the dowser, an object of study of primary importance for the operator who wants to keep himself in good shape and for the public who will discover, in its apparent simplicity, the true key of the dowsing world.

THE TRANSPARENT RESEARCHER LE GALL

Fig. 5. — Le chercheur transparent

This researcher is a rigid, colored and transparent sheet which makes it very easy to apply our method of dowsing research on a plan, sketch or anatomical board: the use of our method and, consequently, of this researcher, avoids errors, so common especially among beginners.

Manual:

First agree that the pendulum will rotate when the right edge of the seeker reaches the point receive on the plane. The right part of the seeker being then maintained at the top and horizontally, slide it on the plane until it has reached the sought point which will be designated by the gyratory movement of the pendulum. You obviously have to think hard about what you are looking for and focus your attention on the plan.

When the pendulum starts moving (or changes its movement), it means that the place sought on the map has just been touched by the rectilinear edge of the seeker. Immediately immobilize the latter. To find the precise point, a second dowsing operation is necessary: explore with a pencil or some other pointed object the rectilinear edge of the seeker, looking at it attentively and thinking strongly about what one is looking for, it being agreed that the pendulum will turn when the tip of the pencil will pass through the point sought. At this point, mark the point.

Remark:

The transparent finder is far superior to any ruler or strip of paper used by some operators because, with this finder, the entire plane or the entire anatomical board remains visible and the line of exploration is perfectly defined: two conditions for success which are thus exactly fulfilled.

THE UNIVERSAL REPORTER LE GALL

Fig. 9. - Le rapporteur universel « Le Gall »

Although it is in the form of a circle, it is made up of three sectors of 120 degrees which will be used separately to carry out measurements by means of a moving needle around the axis of the protractor:

- a) a sector graduated from 0 to 100 makes it possible to measure all the percentages and in general all the quantities whose measurement is between 0 and 100;
- b) a sector graduated from 100 to 220 makes it possible to measure the corresponding values: 100 to 220 or 10 to 22 (in the latter case, the tens are considered to be units)
- c) a sector graduated from 34 to 42, used to measure the temperature of the human body.

The central needle is made mobile by means of an operating button.

Instructions for use of the LE GALL protractor:

Let's take an example: measuring the pulse of a person placed near you.

Turn the dial (which is mobile around its axis) so that the 0-100 sector is on the right, the easily legible figures thus being in the normal direction of writing.

Take, in your left hand, the needle operating button.

We are then ready to carry out the control of the pulse by the normal dowsing operation which we repeat below:

- 1) Ask the question: what is the pulse of this person, that is, the number of pulsations of blood in his arteries in one minute.
- 2) Choose the method and the reflex-response: the pendulum will turn when the needle, while traversing the sector 0-100, will pass over the figure which indicates the number of pulsations of the blood of this person in one minute.
- 3) Thinking strongly about the pulse of this person and following with your eyes the figures in front of which the needle passes, wait for the pendulum (launched slightly in oscillation) to start turning.
- 4) Express the solution: announce the number on which the needle was when the pendulum began to turn:

It is that of the frequency of the pulsations in the examined person.

We will do the same to measure his temperature, his vitality, his blood pressure, etc. and - in general

- anything that can be measured.

Note I. - As no inscription is worn on the protractor, it can be used for any purpose. In practice, it is the 0-100 sector that is most often used and it can be used to measure millimeters, centimeters, meters, kilometers or any other measurement, depending on the value given to the unit.

Note II. - In the 0-100 and 100-220 sectors, only the tens are marked, but the units can also be easily measured: thanks to the dots which designate the halves of the tens (15, 25, 35, etc.), we can easily locate all the units (eg 41, 42, 43, 44, 46, etc.).

Do not forget that the measurements are intuitive since they are obtained unconsciously and not by real reading as in ordinary cases of measurement.

Here is how the needle should be handled: instead of moving it with regular slowness over the sector as if trying all the digits one by one, bring the needle in jerks from the middle of a sector division to the middle of the neighboring division asking: "Is it in this division that the number you are looking for is found?". With a little practice, quickly taken, one feels the division in which the measure is. All that remains is to explore this division to obtain the precise measurement.

In this way, we operate quickly and speed is one of the factors of success.

HOW I DISCOVERED URANIUM

TO THE PENDULUM AND TO... 400 KM.

Articles published in the Review "Initiation et Science", N° 42

An industrialist came to consult me one day for a theft in his factory and the conversation continued well beyond this small affair. He told me of his desire to sell the factory and equipment to devote himself to various prospecting.

" I have some knowledge of geology, he told me; if you were interested, we could combine our skills. The association of a dowser and a geologist must be of excellent performance.

- "I think so too", I replied.

And I showed him the duplicates of some research files established for mining companies.

- How do you operate, only on cards?

- Yes, on maps, sketches, various plans and aerial photos.

I am entrusted with these documents and I establish a file comprising two types of documents:

1° one or more layers which determine the locations of the deposits. For France, I generally start with the Michelin Map and end with an extract from the cadastral map.

(2) a table indicating for each deposit its importance and its average depth.

For very important deposits, I give a sketch representing the cut according to a line drawn on the tracing paper; this dimensioned section determines the dip which is so useful to know in order to predict the best operating conditions.

Here is an example:

- The industrial geologist seemed satisfied with this presentation of radiesthesic research but he wanted additional details:

"What do you call size of the deposit and average depth?

- I quantify the importance of 0 to 10, agreeing that 10 would correspond to the deposit dreamed up by the Company, one where everything would be exceptional: dimensions of the deposit, grade of the ore, ease of exploitation, etc... The average depth is that which corresponds to the middle of the thickness of the vein as you see it on the XY section (fig. 2).

- I find this fantastic and I would never have believed dowsing capable of providing such indications but you amaze me with your importance rating which seems to me quite random because of the uncertainty of the calibration; what is the importance 10 deposit?

- Your objection is valid, but practically this uncertainty does not offer any inconvenience; if the client of the dowser knows in the region or elsewhere a deposit already exploited he only has to ask the dowser to quantify the importance and the other measures will thus be used by comparison. Even without these reference measurements, the figures in the table determine the respective values of the deposits appearing on the tracing and can usefully influence the decision.

- Well! What should I do? Tell you what prospecting interests me and bring you the maps of the region where I would like to start?

- Yes; What is it about?

- I feel like looking for uranium.

- Why not?

- On the geological map of France, I have noted, apart from Auvergne, three regions where the granite soil gives hope for uranium at shallow depth: the Vosges... and... of uranium witness to do your dowsing research?

- Not at all since I know what I'm looking for: uranium ore. We'll see what's discovered."

The Monday following this conversation I began research on maps at 1/50,000 of the surroundings of Remiremont and in front of the very interested geologist I marked several points where my reflex as a dowser announced to me the presence of uranium ore; measuring the depths with my universal protractor, I had a pleasant surprise.

"Do you see this charcoal cross that I have just traced; you will find uranium there at less than 30 centimeters.

- Uranium in outcrops as in the Aveyron then; it is quite rare. I'm going to check it tomorrow with the latest model Geiger counter that I just bought for 250,000 francs. But I see that you have found a nice area which must be 600 meters in length; what is its depth?

- Look at the needle of the protractor and my pendulum reflex: I find in vertical section uranium ore from... 4 meters up to... 40 meters approximately. Here is for this deposit the line of the table which will be attached to the layer

Deposit	Importance	Depth	Thickness
VS	5	20	35

- Very well; while waiting for your complete work, I will look for your uranium at 25 centimeters and I will bring you back a piece of it".

What was done; I have since the following Thursday a fine piece of pitch-colored pitchblende (pitch, pitch) the size of half a "very fine" pea which was found at the place I had indicated at the depth of an iron of spade. Reddish stones with large black and radioactive streaks were also sorted for analysis by the Atomic Energy Commission.

Faced with this convincing result of the radiesthesic research, Mr. Pupetto, the industrial geologist, decided to exploit the deposit that my table indicated as the most advantageous.

In a few days, all the necessary formalities were completed. The Atomic Energy Commission, the Mines Department, the Prefect of the Vosges were officially informed and an exploration permit was granted. After agreement with the Mayors, the first trenches were dug and the uranium mines of Basse sur le Rupt (Vosges) and other places began to provide the precious ore which would be richer than that of the Black Forest according to a communication made by M Georges JURAIN at the Academy of Sciences.

Mining is carried out under the following conditions: the production of the mine is paid 8,000 francs per ton for a uranium content of 1/1000; condition of sale analogous to that of wine according to its degree of alcohol.

In short, this dowsing research was done simply in an atmosphere of friendly collaboration; on January 16, the geologist wrote to the dowser:

« We are currently four meters deep and it is getting very interesting. Bomb in the newspapers of the East”.

Obviously the opening of a uranium mine on radiesthesic data is a doubly interesting event since uranium is currently in fashion; but if one considers the dowsing technique in itself one sees that this one is in no way modified by the radioactivity of the matter sought. It is not because pitchblende (oxide of uranium associated with other metals) or autunite (phosphate of calcium and uranium) is capable of physical radiation that the dowser can base a research method on this. radiation. Even if the uranium from the Vosges radiated as far as Fontainebleau (and that of Brittany as well) the problem would still remain, a problem of knowledge.

Radiations are useless for the dowser although some colleagues affirm it without being able to say what they do with it: the very simple truth is that man can choose the knowledge he desires and obtain it by means of a technique made up of method and intuition, therefore entirely human: the search for uranium by dowsing therefore has absolutely nothing in common with the disintegration of the atom.

Maurice LE GALL.
